Taking our findings at their face value, it might be thought that it makes little difference whether the strip rats show no detectable effects of radiation because the radiation is genetically ineffective at very low dose-rates, or because its effects are completely counterbalanced by natural selection, or because an increase in genetic variance is completely absorbed by a corresponding decrease in environmental variance. So far as the parameters which we have used are concerned, that is certainly so. But we have used these entities to probe a wider problem. If it were true that radiation-induced genetic variance has been added cryptically, below the surface, to the iceberg called phenotypic variance, the same presumably would have happened with genes with major pathological effects which could not have been detected by our method. Whereas our findings thus give no positive indication of genetic damage to the rats living on the strip, they do not rule out the possibility of induced mutations lurking beyond the reach of our method.

GENERALIZATION OF EPIDEMIC THEORY

AN APPLICATION TO THE TRANSMISSION OF IDEAS

By Dr. WILLIAM GOFFMAN
Center of Documentation and Communication Research, School of Library Science, Western Reserve University
AND
Dr. VAUN A. NEWILL
School of Medicine, Western Reserve University, Cleveland, Ohio

ONE of the most fundamental problems in the field of information retrieval is that of determining the circumstances under which it might be necessary to introduce an information retrieval system as an aid to a given population of scientists. It is proposed that this problem be examined in terms of the transmission and development of ideas within a population. Specifically, the transmission of ideas within a population will be treated as if it were the transmission of an infectious disease, that is, in terms of an epidemic process. An attempt will be made to indicate the role of information retrieval in the development of such a process.

The Epidemic Model

Since the spread of disease in a population is to be our model for the transmission of ideas, it is appropriate to discuss the essential principles pertinent to this issue. These principles are a part of epidemiology. The necessary elements involved in the process of the spread of an infectious disease are those of : (1) a specified population ; (2) an exposure to infectious material. The members of the population belong to 1 of 3 basic classes at a given instant in time : (a) *infectives*, those members who are host to the infectious material ; (b) *susceptibles*, those who can become infectives given contact with infectious material ; (c) *removals*, those who have been removed for one of a variety of reasons such as death, immunity, hospitalization, etc. These latter members may have been either susceptibles or infectives at the time of their removal.

The entire process is time-dependent, that is, a sequence of events occurs which describes the process. An individual is exposed to infectious material either by direct contact with an infective or through some intermediary host or vector. The exposed person may either be resistant to the incoming organism, in which case the organism is rejected, or may be infected by it, in which case the invading organism proceeds on a course of development. The time interval in which the development takes place is called the 'latency period' (or incubation period), that is, the interval of time necessary for a susceptible to be transformed into an infective. In other words, the latency period is the time between the receipt of infectious material by a susceptible and the time at which he is in position to transmit infectious material to another susceptible, thus repeating the process. An epidemic occurs when the process of susceptibles being transformed to infectives crosses a certain threshold. (The American Public Health Association (1960) defined an epidemic as "the occurrence in a community ... of a group of illnesses of similar nature, clearly in excess of normal expectation.")

The process already described here does not take into account the almost endless number of complexities which actually arise. It is a model, that is, an idealization of the real situation in which the complex process is reduced to its essential properties.

Transmission of Ideas as an 'Epidemic' Process

In general, the 'epidemic' process can be characterized as one of transition from one state (susceptible) to another (infective) where the transition is caused by exposure to some phenomenon (infectious material). The process need not be restricted to infectious disease but is a more general abstract process that might be applied to many situations. All that is needed is the appropriate interpretation of the process elements, that is, susceptibles, infectives, removals, infectious material, intermediary host, latency period, disease, etc.

People are susceptible to certain ideas and resistant to others. Once an individual is infected with an idea he may in turn, after some period of time, transmit it to others. Such a process can result in an intellectual 'epidemic' (Table 1). For example, consider the development of psychoanalysis in the early part of this century. Freud was no less host to the infectious material of the 'disease' of psychoanalysis than the person carrying the organism capable of transmitting a cold, nor is his writing less of a 'vector' carrying the 'infectious material' than the mosquito as a carrier of malaria.

Moreover, Abraham, Ferenczi, Jung and Jones were no less 'susceptibles' who were infected by the ideas of Freud and who, after a certain latency period, themselves became 'infectives' than are those individuals infected by the droplets expressed by a cold carrier. Jung might represent an example of acquired resistance to the disease while the resistance of the medical community of Vienna could represent innate immunity. The development of the psychoanalytic movement in the early part of the twentieth century was in its way no less an 'epidemic' than was the outbreak of influenza in 1917 and 1918.

One can argue similarly that Darwin and evolution, Cantor and set theory, Newton and mechanics, and so on, were examples of 'epidemics' in the world of scientific thought which were instigated by the introduction of a single infective into a population. The analogy is not restricted to science; for examples such as Christ, Buddha, Moses and Mohammed can be cited in the

Table 1. Analogy between Infectious Disease and Intellectual Epidemics

Elements of the epidemic process	Elements interpreted in terms of Infectious disease epidemic	Intellectual epidemic
Host		
Agent	Infectious material	Idea
Infective	Case of disease	Author of paper
Susceptible	Person who will be infected given effective contact	Reader of paper who will be infected given effective contact
Removal	Death or immunity	Death or loss of interest
Vector		
Agent	Infectious material (as for host)	Idea (as for host)
Infective	Vector harbouring the agent	Paper containing useful ideas
Susceptible	Vector not harbouring the agent	All papers containing potentially useful ideas
Removal	Death	Deletion or loss

religious field and other examples can be given almost endlessly.

Although biological and intellectual epidemics can be considered as special cases of a general process, there are important differences. Intellectual epidemics are often desirable while biological ones usually are not. This difference, however, does not pertain to the structure of the processes but only to external factors which might be introduced. In one case, one usually wishes to enhance the process, while in the other to eliminate it.

Another important difference relates to the infectious material. In the biological case the infective individual produces infectious material that closely resembles that which started the process ; there has been little mutation or change. Such is not the case with the intellectual epidemic, for here some mutation or change of the original idea (infectious material) is prerequisite to placing it in print.

Ideas are transmitted by personal communication or by publication. An epidemic cannot develop within a given population unless there is effective contact between the susceptibles and infectious material. The purpose of an information retrieval system is to provide such effective contact where it does not already exist. If such is the case, an information retrieval system might be introduced even though such systems are limited to the transmission of ideas contained in published material.

The essential question is : when is it desirable to introduce a formal information retrieval system into the intellectual activity of a population of scientists? Here the epidemic model may be of value for it permits the rephrasing of the question in terms of epidemiological problems such as : (1) the transmission and spread of the disease ; (2) the prediction of the epidemic course ; (3) the discovery of the threshold densities of the population that might be passed before an epidemic can develop. The answer to these epidemiological questions might help to decide when an information retrieval system should be introduced.

Mathematical Models

There has been extensive development of abstract mathematical models in the theory of epidemics which can be put to general use. There are two types of models, namely, deterministic and stochastic. The deterministic approach represents the process as a system of differential equations while the stochastic approach describes the process as a finite state Markov process of either a discrete or continuous parameter (the discrete parameter is applicable where the latency period is constant, in which case the infectives occur in generations) depending on the physical situation. The stochastic representation, though generally more realistic, is mathematically more sophisticated. An excellent detailed treatment of this subject as related to infectious disease can be found in Bailey[1].

A Deterministic Model

The most natural avenue for exploring the process of the transmission of ideas within a population would seem to be by way of the literature produced by the members of that population. Although the published article is not the only way in which ideas can be transmitted, it does play an important part. We are interested in studying this role, for it is only in this respect that an information retrieval system can be justified at present. In terms of the epidemic process we are therefore concerned with the transference of infectious material, that is, ideas, between human hosts by means of an intermediary host or vector, namely, the written article.

We wish to study the spread of the 'disease' D within the population N of the discipline F. Consider a certain field (F) such as medicine and a certain subfield (D of F) such as medical epidemiology. The field (F) need not be as broad as medicine, but might be epidemiology, and mathematical epidemiology might be the subfield (D). N must be specified because D might develop into an 'epidemic' in some population N_1 but not in some other N_2. For example, the 'disease' of mathematical epidemiology will probably follow different courses in the fields of epidemiology, where it might become an 'epidemic', and in the field of mathematics, where it probably will never become an 'epidemic'. An additional example from the field of medicine might be the present epidemic of cancer of the lung among smokers that is certainly different from the pattern of development of the disease among non-smokers.

Let N_0 be the set of authors who have written papers in F at time t_0, where t_0 represents the starting time of the process. Let I_0 be the set of authors who have written papers in D at time t_0. Then I_0 represents the infective population at the beginning of the process. If it is assumed that there are no removals at time t_0, then $S_0 = N_0 - I_0$ represents the susceptible population at time t_0. (Removals constitute those members of N who for some reason or other are no longer producing papers in F.)

Let I'_0 be the set of articles produced in D by the members of I_0 at time t_0 and S'_0 be the set of articles produced by the members of S_0 at t_0. Then $N'_0 = S'_0 + I'_0$ constitutes the vector population at time t_0.

In general as the process develops we have $N = S + I + R$ and $N' = S' + I' + R'$, where R and R' represent removals. At time t_0, $R_0 = 0$ and $R'_0 = 0$.

The process might be described as follows : A member s of S is infected by a member of I'. After a certain length of time (latency period) s becomes an infective and gives birth to new infections in N' which in turn may infect other members of S and so forth. In other words s produces a paper in D in which he cites a paper in I'. (The member of I' might contain more than one idea (more than one type of 'infectious material') with respect to D. This same member of I' may contain ideas that could also infect members of a sub-field other than D. Our only interest in the member of I' is as a carrier of the 'infectious material' of D.) By producing this paper he has introduced a new infective in N'. He may also have cited papers in S' as well, so that he has infected or associated members of S' with the 'disease' D. The appearance of the paper written by s in D indicates that he has made the transition from the susceptible to the infective state.

Let β be the rate at which the members of S become members of I. Hence, β is the rate of infection in the population N. Let β' be the rate of infection in the population N'. Then β' represents the rate at which papers in S' are being cited by members of N who are producing papers in D.

As the process develops with time, a certain number of susceptibles and infectives in the host and vector populations are removed. In the case of the host population this removal might be loss of interest, death, etc. In the case of the vector population it might be lack of citation due to deletion, inaccessibility, etc. Let γ (γ') be the rate of removal of infectives I (I') and let δ (δ') be the rate of removal of susceptibles S (S').

Another aspect of the process as it develops is that new supplies of susceptibles and infectives are introduced into the populations N and N'. Let μ (μ') be the rate at which new susceptibles are introduced and let υ (υ') be the rate at which new infectives are introduced. That is, μ represents the rate at which new authors are introduced in F but not in D, while μ' is the rate at which new papers are introduced in F but not in D. υ represents the rate at which new authors are introduced in D and υ' the rate at which new papers are introduced into D.

The mathematical model to be presented includes the following states of transition of the host and vector populations within a short time interval Δt : the susceptible can remain a susceptible or become an infective

Table 2. States of Transition of the Host and Vector Populations*

State to which an individual belongs	
At time t	At time $t+\Delta t$
(1) Susceptible	Susceptible, infective or removal
(2) Infective	Infective or removal
(3) Removal	Removal

* In general the host and vector populations need not follow the same transitional patterns as in this case.

or removal, the infective can remain an infective or become a removal, and the removal must remain a removal (Table 2). (To keep the mathematical model simple in this presentation, we are not permitting immunes to lose their immunity and to return to the susceptible population.) The latency period is assumed to be zero so that infectives occur continuously with time. If we assume homogeneous mixing among the members of the populations, the total process can be deterministically described by the following systems of differential equations :

$$\frac{dS}{dt} = -\beta SI' - \delta S + \mu \quad : \quad \frac{dS'}{dt} = -\beta' S'I - \delta S' + \mu'$$

$$\frac{dI}{dt} = \beta SI' - \gamma I + \upsilon \quad : \quad \frac{dI'}{dt} = \beta' S'I - \gamma' I' + \upsilon'$$

$$\frac{dR}{dt} = \gamma I + \delta S \quad : \quad \frac{dR'}{dt} = \gamma' I' + \delta' S'$$

A threshold density of susceptibles can be obtained if we assume initial conditions of a single infective introduced into the host (N_0) and vector (N'_0) populations at time t_0, that is, $N_0 = (S_0, 1, 0)$ and $N'_0 = (S'_0, 1, 0)$. For an epidemic to develop from time t_0, the change in the number of infectives in both the host and vector populations must be positive. Hence, from the above differential equations, we obtain the threshold $\rho\rho'$ as follows :

$$\beta SI' > \gamma I - \upsilon$$

$$\beta' S'I' > \gamma' I' - \upsilon'$$

$$\text{or } \beta\beta' S_0 S'_0 > \gamma\gamma' - \gamma\upsilon' - \gamma'\upsilon + \upsilon\upsilon'$$

$$\text{and } S_0 S'_0 > \left(\frac{(\gamma - \upsilon)}{\beta}\right)\left(\frac{(\gamma' - \upsilon')}{\beta'}\right) = \rho\rho'$$

$$\text{where } \frac{\gamma - \upsilon}{\beta} = \rho \; ; \text{ and } \frac{\gamma' - \upsilon'}{\beta'} = \rho'$$

The epidemic curve which traces the development of the epidemic in time is given by the differential equation $\frac{dI}{dt} = F(t)$ with peaks at the points in time where $\frac{d^2I}{dt^2} = 0$. The size of the epidemic is given by the limit of I as t goes to infinity, that is, the size of the infective population I after a long period of time. This discussion indicates that an epidemic can only develop from time t_0 provided that the product of the host and vector susceptible population exceeds the threshold $\rho\rho'$. When a potential epidemic condition is present, the quantity of scientists and information is sufficiently large that given effective contact an epidemic can develop. It is at this time that an information retrieval system might be introduced.

If the population is already in an epidemic state, an information retrieval system can be introduced in order to maintain or increase the frequency of effective contacts between susceptibles and infectives. Hence, the points at which an information retrieval system might be usefully introduced into a population are either at the initial point or the peak of the epidemic process or at a time when intensification of the epidemic process is desired.

Other models different from the one we have presented could be constructed that would interpret the epidemic in a different manner. For example, a model can be elaborated by introducing two interacting populations with rates of migration from one population to the other. One population might consist of biostatisticians and the other of epidemiologists. The 'disease' could be statistical epidemiology. Then one might study the development of the field in terms of the interacting host and vector populations rather than in terms of single populations.

The Stochastic Approach

In a stochastic model of the process described above the actual number of new infectives occurring in a short time-interval would be replaced with the probability of a new case occurring in that interval. This type of mathematical treatment is particularly applicable when dealing with small populations.

An epidemic process within a large population can be characterized as a collection of epidemic processes within sub-populations. For example, the outbreak of an infectious disease in a community might more specifically be studied in terms of the household populations rather than the community as a whole. Similarly the intellectual epidemic process within the population of a certain discipline could be studied in terms of its sub-populations, that is, the 'disease' D of field F might be studied in terms of the sub-fields of F, indicating, from the point of view of information retrieval, where intellectual epidemics are developing in a given discipline.

Thus, a stochastic treatment of the epidemic processes would in general be more desirable because the size of the populations being studied has been reduced. Unfortunately a stochastic model of an epidemic process with a vector population does not exist as far as we know. Such a model is in need of development and attention is being given to this problem by the authors.

Deterministic models, however, can be very useful, particularly in dealing with large populations, and experiments have been designed for the purpose of testing the model presented above.

Discussion

The construction of a mathematical model of a complex physical situation involves a certain amount of simplification. This is because the purpose of the mathematical model is the description and prediction of the essential patterns of the physical process and not the achievement of its complete analysis.

A total understanding of the process requires studies complementary to the mathematical ones. In the case of the infectious diseases this means biological, ecological, and clinical investigations of the process as well as mathematical ; in the transmission of ideas, psychological, sociological, and linguistic studies.

Mathematics cannot indicate why exposure to a certain virus will lead to infection or why a certain article will infect the reader with an idea. These important questions must be answered elsewhere. However, mathematics can make important contributions toward an understanding of the epidemic process if one keeps its limitations in mind.

Of course, the usefulness of a mathematical model depends on : (1) being able to solve the model ; (2) obtaining reliable measurements in order to test it. These are by no means negligible problems, since even the most simple representations present difficulties in obtaining algebraic solutions. This is particularly true of the stochastic case. Additional problems are encountered in relation to defining populations and obtaining reliable estimates of the parameters of the process.

Although implementation of the epidemic model presents certain difficulties, much useful information concerning the transmission of ideas within a population might be obtained from the mathematical approach. It could help in answering several questions that are basic for the design and operation of information retrieval systems. These questions include : (1) Where and when is activity within a given discipline developing into 'epidemic' proportions ? (2) What is the expected

duration of this 'epidemic' activity? (3) What is the intensity of the 'epidemic'? (4) What are the classic papers of a certain discipline, that is, the initial infectives of an outbreak?

Information retrieval systems must be dynamic and should reflect the interactions between the researcher and the literature. It seems that the 'epidemic' approach is a workable method for describing and predicting certain fundamental aspects of this interaction.

Since the process of transmitting ideas, as in the case of an infectious disease, is not a single process within a population but a collection of interacting processes within sub-populations, it would seem that the notion of an all-encompassing information retrieval system spanning the totality of knowledge should be replaced by the notion of small dynamic interrelated systems that appear when needed and disappear when not needed.

'Epidemic' theory could have a wide range of applications other than to the transmission of ideas, for example, to the study of certain chronic diseases, divorces, accidents, etc., but these will not be elaborated on in this report.

This work was supported by AFOSR grant 403–64 and U.S. Public Health Service grant *AM* 06399–03.

NEWS and VIEWS

Director of the Rowett Research Institute, Aberdeen: Dr. D. P. Cuthbertson, C.B.E.

Dr. D. P. Cuthbertson, who will be retiring from the directorship of the Rowett Research Institute, Bucksburn, Aberdeen, on September 30, 1965, obtained his medical qualification in Glasgow and was for nearly twenty years lecturer in pathological chemistry and physiological chemistry in the Royal Infirmary, Glasgow, and in the University of Glasgow. He became an authority on the biochemical effects of injury, and particularly on the acute depletion of protein following injury. His work on the prevention and treatment of these changes became of especial importance during the Second World War. Cuthbertson worked for two years on the headquarters staff of the Medical Research Council before he was appointed director of the Rowett Research Institute, Aberdeen, in 1945. Under his influence the Institute grew rapidly in size and importance, and it is remarkable how Cuthbertson was able to direct so much work and produce an interesting report each year, summarizing work that had been published in 100 papers or more. He managed, however, to keep his own laboratory going and to give a number of lectures, which were published. He is an accomplished artist in water colours and a keen golfer, and will clearly be able to find something to do when he retires.

Dr. K. L. Blaxter

Dr. K. L. Blaxter, at present head of the Nutrition Department, Hannah Dairy Research Institute, has been appointed to succeed Dr. Cuthbertson as director of the Rowett Research Institute. Dr. Blaxter, who is forty-five, is a graduate of the University of Reading. He has been with the Hannah Dairy Research Institute since 1948. Before that he was a research officer at the Veterinary Laboratory of the Ministry of Agriculture, Weybridge. During 1946–47 he was a Commonwealth Fund Fellow at the University of Illinois, Division of Nutrition, under Prof. H. H. Mitchell. With the exception of a period of war service with the Royal Artillery, he was a research assistant at the National Institute for Research in Dairying from his first graduation until going to Weybridge. Dr. Blaxter was Clive Behrens Lecturer in the Faculty of Agriculture, University of Leeds, during 1958–61; 1960 Thomas Baxter Prizeman and Gold Medallist (for research on the nutrition of dairy cattle); National Research Council of Canada visiting lecturer to the Universities of British Columbia, Manitoba, Saskatchewan and Alberta in 1964; 1964 Royal Agricultural Society Gold Medallist (for research on the nutrition of farm livestock). He also gave the Fernhurst Lecture to the Royal Society of Arts in 1962, lectures to the Professors Council of the University, Uppsala, and to the Berlin Academy of Sciences, D.D.R., in 1962, and the third Samuel Brody Memorial Lecturer in the University of Missouri in 1964. Dr. Blaxter's work has been concerned with the nutritive value of home-grown foods for dairy cattle, food intake and food utilization, protein requirements and protein metabolism of dairy cattle and calves, hyperthyroidism in the ruminant and the use of iodinated protein, hypomagnesæmic tetany, vitamin E metabolism and muscular dystrophy, energy metabolism and the energy requirements of cattle, and their relation to the environment. In 1962 his monograph entitled *The Energy Metabolism of Ruminants* was published. Dr. Blaxter is a member of numerous learned societies and is a member of the joint Agricultural Research Council–Medical Research Council Development Commission sub-committee on the monitoring of radioactive fall-out and of the Working Party on Ruminants of the Agricultural Research Council's Technical Committee on Nutrient Requirements of Farm Livestock.

Ministry of Aviation: Director of Engine Research and Development (1): Mr. Dennis H. Mallinson

Mr. D. H. Mallinson has been appointed director of engine research and development (1), Ministry of Aviation, in succession to Dr. J. Remfry, who has retired from the Public Service. Born in 1921, Mr. Mallinson was educated at Prince Henry's Grammar School, Otley, before going to the University of Leeds in 1939. He graduated with honours in applied mathematics in 1942 and was posted as a junior scientific officer to the Engine Department of the Royal Aircraft Establishment. As a member of the small but growing turbine division under Hayne Constant and W. R. Hawthorne, he was employed on engine performance investigations and particularly on the analysis of results from the flight tests of the pioneer jet aircraft. Transferring with the Royal Aircraft Establishment's Turbine Division to Power Jets, Research and Development, Ltd., he remained on engine performance work and was in charge of the Performance Section when the National Gas Turbine Establishment came into being. In 1949, following a period of about a year in which he acted as technical and administrative assistant to the deputy director (Mr. Peter Lloyd, the present director-general of engine research and development), Mr. Mallinson became a member of the National Gas Turbine Establishment's ramjet research team under Mr. R. P. Probert, concentrating first on thermodynamics but later encompassing fuel control systems and combustion development and finally assuming responsibility for the full-scale ramjet test vehicle programme. This programme was successfully completed in 1957 and from then until early 1963 he was superintendent of the Engine Research Division at the National Gas Turbine Establishment in charge of work on propelling nozzles, control systems and high-speed ramjets. He transferred to Ministry of Aviation Headquarters, London, in February 1963 as assistant director responsible for engine project assessment and continued in this post until receiving his present appointment. Dennis Mallinson is a district commissioner of the

Boy Scouts Association and is responsible for scouting in the Odiham District of Hampshire.

Counsellor, Defence Research and Supply, British High Commission, Ottawa: Mr. G. L. Hunt

Mr. G. L. Hunt, who has been appointed Counsellor, Defence Research and Supply, British High Commission, Ottawa, received his training at H.M. Dockyard School, Portsmouth, and the Imperial College of Science and Technology, where he graduated with honours in electrical engineering. After some time in industry, where he worked first on the development of carrier telephone systems, and later on thermionic valves, he joined the Royal Aircraft Establishment Radio Department, to continue in the field of valve research and development. In 1945 he was appointed assistant-director, electronics research and development, Ministry of Aircraft Production, where he was responsible for valves, components and test equipment. Later he changed to electronic systems work to be responsible for aircraft navigation systems and electronic warfare systems. In 1957 he returned to the Royal Aircraft Establishment as senior principal scientific officer to take charge of a division of the Radio Department which has embraced groups working on air–sea warfare, passive electronic warfare and radar techniques. He will be taking up his new appointment some time in October 1964.

U.S. National Academy of Sciences Advisory Group

An *ad hoc* committee of scientists and engineers has been formed by the U.S. National Academy of Sciences to advise Congress on certain national problems pertaining to scientific research. This is the first time in its 101 years of existence that the Academy has been called on to provide continuing advice to Congress. The group will be under the chairmanship of Dr. G. B. Kistiakowsky (professor of chemistry, Harvard University, and chairman of the Academy Committee on Science and Public Policy). An initial survey is being undertaken jointly by the Academy Committee on Science and Public Policy and the House Sub-committee on Science, Research and Development, under the chairmanship of Congressman Emilio Q. Daddario, to determine the areas in which the Academy is best equipped to give advice.

The *ad hoc* group has been asked to look into the following questions: (1) What level of Federal support is required for the United States to maintain a position of leadership through basic research in the advancement of science and technology and their economic, cultural and military applications? (2) What judgment can be reached on the balance of support now being given by the Federal Government to various fields of scientific endeavour, and on adjustments that should be considered, either within existing levels of over-all support or under conditions of increased or decreased over-all support? Although the Academy is composed entirely of Americans who have gained distinction in the natural sciences and engineering, membership in the present advisory group has been broadened to include social scientists in the fields of business administration, economics and public administration. Because of the breadth of the questions as well as the diversity of the views of the membership, the final report of the group will present individually signed statements rather than seek a formal consensus. In addition, the report will summarize the views of the individual contributors and tally their responses to specific questions. It will be delivered to the Daddario subcommittee before the end of the year.

Academic Forecast for the United States, 1965–75

A science resources planning study by Dr. W. A. Consolagio, entitled "Sustaining Academic Science, 1965–75", and reprinted from *The Educational Record*, estimates that during this period 2·6 million bachelor's degrees will be awarded in the United States in science, engineering and mathematics, together with 480,000 master's degrees and 130,000 doctor's degrees. For this output, a full-time science and engineering faculty of 173,000 will be required, 95,000 of whom hold doctorates, and, in academic science and engineering, man-power at trainer and trainee level will approximately double between 1965 and 1975. Instructional costs for the decade are put at 28,000 million dollars, with 15,000 million dollars for research, 7,000 million dollars for assistance to Fellows and Scholars, and 2,500 million dollars for information services, and a like sum for improving education in science and mathematics below this level. Dr. Consolagio suggests that the vital question is not the national need for such man-power, but whether the nation has the resources to train all who seek such training; whether it can, in fact, afford this effort, conservatively estimated at 65,000 million dollars.

Science and Technology in Relation to Politics

The third issue (Summer 1964) of *The Technologist* is devoted to a series of articles on science and technology in relation to politics, and an editorial article, "The Politics of Maturity", suggests that the type of society created by science and technology demands a policy of maturity. Mr. Denzil Freeth writes on the Conservative and Mr. A. Albu on the Labour attitude. Dr. S. Toulmin contributes a shortened version of his paper, "The Foundations of Scientific Policy", and Lord Bowden is interviewed on the technologist in politics. Drs. F. E. Nord and M. K. Malhotra describe the pattern of the organization of scientific research in the United States, Dr. D. W. Hill discusses technology as a vocation, Mr. E. Minshall deals with research and the atmosphere of the colleges of advanced technology, and Dr. R. A. Buchanan contributes a rather circumscribed bibliographical review on science and Government. Despite an occasional naïveté, the number gives a useful conspectus of present debate on the topic.

Diploma in Technology

The report of the National Council for Technological Awards for the period April 1963–March 1964 records 8,718 students attending 122 courses leading to the diploma in technology; 3,211 were first-year students. The diploma in technology conferred on 1,073 students during the year brought the total conferred since 1958 to 3,092, while there are now 106 registered candidates for membership of the College of Technologists, an award which was gained by four students during the year. Of 4,318 industry-based students in engineering, 61 per cent were wholly supported by industry and 39 per cent assisted by public funds for the academic part of the course; for 1,058 students in other technologies the corresponding figures are 65 and 35 per cent. The overall failure rate for entrants to courses in 1959–60 was 31 per cent (32 per cent in engineering and 28 per cent in other technologies). Of 933 entrants to colleges of advanced technology, 68 per cent gained the diploma of technology; for 228 entrants to regional and other colleges the figure was 71 per cent. A list of 131 courses at 31 colleges now recognized by the Council as leading to the diploma in technology is appended, as well as lists of industrial organizations which have provided industrial training and of approved external examiners.

Industrial Archæology

Much has been written of the various industries of the Sheffield area but, for one reason or another, the history of the South Yorkshire glass industry has been neglected. A small excavation was recently organized by the Sheffield Museum at the Catcliffe glasshouse, when it was threatened with destruction. As a result of the interest then aroused, and the discovery of a number of pieces of authenticated local glass in private hands, an exhibition of South Yorkshire glass was arranged at the Sheffield Museum in March and April 1963. The Museum

has a collection of glass, assembled by the late Joseph Kenworthy and attributed to the Bolsterstone glasshouse. An account of the history of the industry has been prepared by the deputy director, Mr. G. D. Lewis] (*The South Yorkshire Glass Industry*. Pp. 4. Sheffield: The City Museum, 1964. 6*d*.). The author directs attention to an increasing awareness of the lack of knowledge concerning many of the fast-disappearing industrial monuments which played an important part in Britain's technological development. Of this destruction, the Catcliffe glass-cone speaks eloquently. It is the last survivor of at least six such cones known to have been built in the area and is the oldest in Europe; only five others remain in Britain.

Archæology in Northern Rhodesia and Turkey

In the journal *Man* for May–June 1964, besides a number of interesting anthropological articles, there are two of more archæological importance. Prof. Desmond Clark directs attention to a small number of special-shaped stone vessels from Northern Rhodesia which he equates with some already known from South-West Africa (Waterbeg) and Tanganyika. He further suggests an affinity with others from further north in East Africa, and postulates a small migration of a pastoral people passing south and south-west. The article is illustrated. No dates can be given. There is also an account of some crude and primitive animal paintings in a small cave site in the Taurus mountains in Turkey. The site is not far from the town of Seydişiher. The cave is visible from miles away in the east-facing side of a hill called Dolmus Tokadi. There are well-worn tracks up to the site. Prof. Solecki, of Columbia University, does not suggest a date earlier than the Neolithic, and compares the new finds with those from Çatal Hüyük, some 85 km to the east, over the mountains, on the Konya plain described a few years ago by James Mellaat. Another somewhat similar find of a painted ibex has been cited by Y. Bostanci from near Beldibi, 140 km to the south-west over the Taurus Mountains. All these rock-shelter sites form an interesting group.

Commercial Oil Production in Australia

A few months ago a brief account was given of the Moonie oilfield, Queensland, the successful results of exploratory drilling there, the potentialities of the area, and particularly the start of a pipe-line from Moonie to Brisbane, 187 miles long (*Nature*, 201, 1080; 1964). On March 25, 1964, the Queensland State Minister for Mines, Mr. Evans, unveiled a plaque at the Moonie field to commemorate a great occasion: the beginning of commercial oil production in Australia. It is recorded that full-scale pumping of the oil through the 187-mile, 10-in. pipe-line then officially commenced, and that production installations are fully automated in the field, all operations being monitored from a central control station at Moonie (*The Australian Mineral Industry Quarterly Review*, 16, No. 4; June 1964). The list of failures in the search for petroleum resources in Australia during half a century or more is depressingly long, but enterprise, determination and patience have at last deservedly met with commercial success. Fully backed by the Commonwealth Government, implementing the Petroleum Search Subsidy Act, 1959, the Moonie strike, though not spectacular by world standards, is an obvious incentive to the vigorous pursuit of more as yet undefined oil-pools in Queensland, if not elsewhere in the Australian continent. In the section on petroleum in this number of the *Review* there is a summary of the present exploratory operations, from which it is clear that Queensland has a strong lead over the other territories in Australia in the matter of drilling activities, judged by the number of wells and total footage completed. It is a measure of progress that drilling activity in Australia in 1963 broke all records and showed an increase of more than 60 per cent over the records for 1962 in both the number of wells and annual footage.

Range Action in Table Bay Harbour

Range action in Table Bay Harbour is well known and is of frequent occurrence. It consists of regular oscillations of the water surface which are initiated by oscillations of similar period in the sea outside the harbour rather than directly by wind or barometric pressure changes. The spectrum of such long waves, recorded at a point on the west coast of the Cape Peninsula, has been examined by Prof. J. and Dr. Mollie Darbyshire (*South African Journal of Science*, 60, No. 6, June 1964). The natural periods of oscillation of the Duncan Dock have been calculated and the selection, by the dock itself, of certain periods from the broad band of the external spectrum is indicated. The amplitude of the shorter oscillations of period 1–6 min is dependent on the amplitude of the ordinary surface waves, whereas the longer ones, of period 15–60 min, are associated with oscillations of the water mass on the continental shelf caused by atmospheric pressure disturbances. Examples of both types of range action, taken from the tidal records in the Duncan Dock, are described.

Urea as a Fertilizer

Urea has held promise as a fertilizer for many years because it contains much more nitrogen than the popular nitrogenous fertilizers, is readily soluble in water and undergoes rapid hydrolysis to liberate ammonia. It is, in fact, an intermediate in the decomposition of calcium cyanamide, which was the first nitrogen compound to be synthesized from atmospheric nitrogen on a commercial scale, and has been used in large quantities as a fertilizer. The commercial production of urea was rather slow to develop and it has been manufactured in the main to satisfy the demand for urea–formaldehyde resin. Some of the earlier agricultural experiments with urea were discouraging since biuret could be present in amounts that were toxic; furthermore, under certain conditions the ammonia arising from hydrolysis of urea could impair the germination of seeds and adversely affect young seedlings; and finally, loss of ammonia from the soil reduced the efficiency of urea as a source of nitrogen in comparison with ammonium salts or nitrates. A fully documented account of the advantages and disadvantages of urea as a fertilizer, of its behaviour in different soils and of the results from field experiments with a variety of crops is given by J. K. R. Gasser in *Soils and Fertilizers* (27, No. 3. Pp. 175–180. Commonwealth Bureau of Soils, Rothamsted, 1964). The uncertainties regarding its value are cleared up and the precautions necessary in order to achieve parity with other nitrogen fertilizers are described. This is a timely review of the position and with the collected references on the subject will be a valuable guide to anyone interested in this particular fertilizer, which is now produced industrially from ammonia and carbon dioxide on a very large scale and sold at a price comparable with other nitrogenous compounds.

Fellowships in Medicine

The following appointments have been made by the Medical Research Council to fellowships in medicine to be held in the United Kingdom, the United States, Canada and Taiwan for the academic year 1964–65.

Clinical Research Fellowships

Dr. P. A. Murphy, registrar, Radcliffe Infirmary, Oxford, to the Department of the Regius professor of Medicine, Oxford; Dr. P. Richards, registrar, St. George's Hospital, London, to the Department of Medicine, Post-graduate Medical School, London; Dr. R. Summerly, registrar, St. Thomas's Hospital, London, to the Medical Research Council Unit for Research on the Experimental

Pathology of the Skin, Birmingham; Mr. P. Vig, Institute of Dental Surgery, Eastman Dental Hospital, London, to the Department of Orthodontics, Institute of Dental Surgery, Eastman Dental Hospital, London; Dr. J. L. Wilkins, registrar, St. Mary's Hospital, London, to the Pædiatric Research Unit, Guy's Hospital Medical School, London.

Medical Research Council Travelling Fellowships

These fellowships replace the Rockefeller travelling fellowships. Dr. M. C. Brain, senior registrar, Department of Medicine, Hammersmith Hospital, London, to the Hæmatology Division, Johns Hopkins Hospital, Baltimore, Maryland; Dr. C. D. Holdsworth, registrar, Medical Unit, Royal Free Hospital, London, to the Department of Physiology, Harvard Medical School, Boston, Massachusetts; Dr. A. H. G. Love, lecturer in medicine, Queen's University of Belfast, to the United States Naval Medical Research Unit, Taipei, Taiwan, and the Gastroenterology Unit, Massachusetts Memorial Hospital, Boston, Massachusetts; Dr. H. Newey, J. J. Graves Medical Research Fellow, Department of Physiology, University of Sheffield, to the Biophysical Laboratory, University of Harvard, Boston, Massachusetts; Dr. V. Parsons, senior registrar in general medicine, Royal Sussex Hospital, Brighton, to the Arthritis Unit, Massachusetts General Hospital, Boston, Massachusetts; Dr. T. H. Williams, lecturer in experimental neurology, Department of Anatomy, University of Manchester, to the Department of Anatomy, Harvard Medical School, Boston, Massachusetts.

Sir Henry Wellcome Travelling Fellowships

Miss M. R. Daniel, cell physiologist, Strangeways Research Laboratory, Cambridge, to the Division of Histology, Ontario Veterinary College, Guelph, Canada, and the Department of Microbiology, the University of Michigan, Ann Arbor, Michigan; Mr. R. P. Gould, senior lecturer in histology, Middlesex Hospital Medical School, London, to the Department of Neuroanatomy, Harvard Medical School, Boston, Massachusetts; Mr. N. Maclean, assistant lecturer, Department of Zoology, University of Edinburgh, to the Rockefeller Institute, New York; Dr. G. Meachim, lecturer in pathology, University of Sheffield, to the Department of Animal Biology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia; Mr. J. L. Provan, senior lecturer, Surgical Unit, University College Hospital Medical School, London, to the Cardiovascular Laboratories, Massachusetts General Hospital, Boston, Massachusetts.

U.S. Public Health Service Fellowships

Dr. M. H. Evans, senior lecturer, Sherrington School of Physiology, St. Thomas's Hospital Medical School, London, to the Department of Physiology, University of Utah, Salt Lake City; Dr. N. L. Jones, senior registrar in respiratory research and senior tutor, Postgraduate Medical School, London, and honorary senior registrar, Hammersmith Hospital, London, to the Cardiovascular Research Institute, University of California Medical Center, San Francisco, California; Dr. J. R. Ledsome, lecturer in physiology, University of Leeds, to the Cardiovascular Research Institute, University of California Medical Center, San Francisco, California; Mr. J. H. P. Main, lecturer in oral pathology, University of Edinburgh, to the National Institute of Dental Research, Bethesda, Maryland.

Alexander Pigott Wernher Memorial Trust Fellowships in Ophthalmology and Otology

Dr. A. J. Bron, junior registrar in ophthalmology, Guy's Hospital, London, to the Wilmer Institute, Johns Hopkins Hospital, Baltimore, Maryland; Dr. P. P. Hakim, registrar, Dudley Road Hospital, Birmingham, to King's College Hospital and the National Hospital for Nervous Diseases, London.

The Royal Society: Research Fellowships

THE Committee representing the Royal Society and the Armourers and Brasiers' Company has appointed Dr. G. A. Chadwick, of the Department of Metallurgy University of Cambridge, to the Armourers and Brasiers' Company research fellowship in metallurgy to work on the effect of the interfacial energy term on the microstructure of eutectic alloys at the Department of Metallurgy, Cambridge. The Committee representing the Royal Society and the University of Sheffield has appointed Dr. R. N. Dixon, of the Department of Chemistry, University of Sheffield, to the Sorby research fellowship to continue experimental and theoretical investigations of the electronic spectra of small molecules at the Department of Chemistry, Sheffield.

Announcements

PROF. A. R. J. P. UBBELOHDE, professor of thermodynamics and head of the Department of Chemical Engineering and Chemical Technology in the Imperial College of Science and Technology, London, and director of the Salters' Institute of Industrial Chemistry, has been elected a corresponding member of the Göttingen Akademie der Wissenschaften.

IN recognition of the centenary of the Cleveland Institution of Engineers, Middlesbrough, which is an Affiliated Local Society of the Iron and Steel Institute, the Institution has been awarded the Medal of the Iron and Steel Institute. This Medal, which was established in 1960, is presented on special occasions to Societies which have, in the opinion of the Council of the Institute, rendered exceptional service to science or industry over a long period. The Medal, which is of gold, has previously been awarded to the Royal Society (1960), the Verein Deutscher Eisenhüttenleute, Düsseldorf, Germany (1960), and Jernkontoret, Stockholm, Sweden (1962).

THE Arthur Stanley Eddington Memorial Lecture for 1964 on "I believe . . ." will be delivered by Dame Kathleen Lonsdale in Cambridge on November 6. Further information can be obtained from the Eddington Memorial Trust, Sedgwick Museum, Cambridge.

A SYMPOSIUM on "Space Environment Simulators", sponsored jointly by the British Interplanetary Society and the Society of Environmental Engineers, will be held at Northampton College of Advanced Technology on November 17. Further information can be obtained from the British Interplanetary Society, 12 Bessborough Gardens, London, S.W.1.

THE first inaugural presidential address of the Institute of Mathematics and its Applications will be delivered by Prof. M. J. Lighthill (Imperial College of Science and Technology, University of London) at a meeting of the Institute to be held at King's College London on November 25. Further information can be obtained from the Institute of Mathematics and its Applications, 29 Gordon Square, London, W.C.1.

CORRIGENDUM. It is regretted that due to a delay in receiving proofs the following corrections could not be made to the communication entitled "Instability of Temperature Ice-sheets owing to a Feed-back Mechanism" by M. L. Lliboutry (*Nature*, 203, 627; 1964): throughout the communication "temperature ice-sheets" should read "temperate ice-sheets", and also "C_0" should be "c_0". Lines 33–35 of the left-hand column on p. 629 should read: ". . . In fact, it has been proved[6] that E must be equal to 1 near the bergschrund and to δ near the front".

THE JOHN INNES INSTITUTE

DR. K. S. DODDS, director of the John Innes Institute, in his annual report* of the work of the Institute, anticipates that with the removal of the Institute to a site near the University of East Anglia it will be appropriate to re-fashion its research activities in the light of modern requirements of agricultural research. Meanwhile, the contents of the report suggest that the Institute maintains its high traditions in genetical research.

The work of the Institute is concerned both with fundamental genetical research and with plant breeding. The Department of Genetics is concerned mainly with the former and work has continued on genetical control of the enzyme NADP-linked glutamate dehydrogenase in *Neurospora* and new mutants and new complementation relationships are reported. Work has continued on the genetics of *Ustilago* with special reference to the effect of inhibitors of DNA synthesis on mitotic crossing-over. The enzyme nitrate reductase has also been investigated in *Ustilago* mutants some of which are unable to utilize nitrate or nitrite. The results suggest that the ammonium ion acts as an inhibitor of nitrate reductase rather than by repressing the formation of the enzyme. The work also suggests that induction of nitrite reductase lags behind that of nitrate reductase. These findings have implications for nitrate metabolism of higher plants. Investigations on *Antirrhinum majus* show that changing the environmental conditions during growth affects the germinal as well as the somatic mutation rate.

Further work in the Department of Cell Biology confirms that much of the rapidly labelled ribonucleic acid in the cell nucleus undergoes breakdown within the cell, largely in the nucleus, to acid-soluble end-products, and it is concluded that much of this short-lived nuclear RNA does not serve as a template for synthesis of protein either in the nucleus or cytoplasm and its function remains obscure. Little is known concerning the relative amounts of DNA and RNA in different parts of the cell nucleus, and attempts are being made to elucidate this on isolated nuclei of different species of higher plants of varying chromosome size. A new technique for isolating nucleoli will help in separating RNA fractions of the nucleus. In cultures of plant callus cells it has been discovered that chlorophyll formation is more adversely affected by certain synthetic auxins than carotenoid formation, but prolonged treatment with high levels of auxins did not impair the ability of the cells to synthesize chlorophyll and on restoration to a lower level they resumed synthesis. In all the callus cultures investigated the rate of carotenoids to chlorophylls was consistently higher than in leaves.

The possibility of devising mathematical models to interpret responses to selection is being continued by the Department of Applied Genetics. Other topics under investigation in this Department include the relative distribution of tomato mosaic virus in susceptible and resistant strains and the genetics of the tomato and the garden pea. The prevalence of the tendency for English garden peas to throw rogues is attributed to the narrow genetic base on which English garden peas are established, many varieties having common ancestors.

The Department of Potato Genetics is responsible for maintaining the Commonwealth Potato Collection and it is providing material for countries interested in potato breeding. Within the Department it provides material for studying the genetics of cultivated diploids, a necessary preliminary to the establishment of useful commercial varieties. Disease resistance and tuber dormancy are also under investigation. The discovery that seed and tuber dormancy may be under a common biochemical control will help to establish stocks of known dormancy.

With Mr. W. J. C. Lawrence's retirement from the Department of Physiology and Plant Culture the results of his work on the rogue tomato are summarized. Investigations into the effects of day and night temperatures on growth of tomato seedlings indicate that optimum temperature régime is a constant temperature close to 25° C but is dependent on the light intensity. Day temperatures affect growth more than night temperatures. The developing leaves respond to temperature more than the cotyledons. Contrary to general belief, it is found that respiratory loss is unaffected by night temperature and in fact a high night temperature is beneficial in stimulating leaf growth by increased cell multiplication. In glasshouse experiments, relatively high night temperatures are found to be beneficial to young plants even under conditions which are at variance with normal commercial practice.

MEDICAL RESEARCH AND THE WORLD HEALTH ORGANIZATION

*THE Medical Research Programme of the World Health Organization, 1958–1963** should be read by all who wish to know what the World Health Organization is doing and has done in the field of medical research. It is a comprehensive survey of the intensified programme of medical research on which the Organization first embarked in 1958. Before that year the promotion of research had, of course, been an integral part of the work of the World Health Organization. In this volume, the director-general, Dr. M. G. Candau, gives for the first time in print a comprehensive report of the medical research programme of the Organization.

The report begins with a general account of the origin, objectives, nature and methods of the programme and the promotion and co-ordination of the work done by co-operative effort in many countries. The programme is directed essentially at the solution of problems that are better tackled by co-operative effort than by local groups, but it is not merely concerned with those projects which the World Health Organization helps financially. Some of the work helped by the Organization involves the collaboration of experts in several scientific disciplines, such as chemistry, pharmacology, biology and epidemiology. Others are carried out in clinical departments in various countries.

A wide range of subjects is discussed in the report and they are grouped under the following five headings: (1) "Communicable Diseases", that is, virus diseases, enteric and diarrhœal diseases, tuberculosis, leprosy, malaria, bilharziasis, diseases caused by spirochætes and filarial nematode worms, other diseases caused by para-

sites and zoonoses. (2) "Non-communicable Diseases", that is, cancer, cardio-vascular, intestinal and rheumatic diseases. (3) "Public Health Practice". (4) "Human Biology and Pharmacology", including sections on immunology; the biological standardization, efficacy, and safety of drugs; human reproduction and genetics (the last-mentioned being the subjects of two recently published issues of the *Technical Report Series*, No. 280† and No. 282‡). (5) "Environmental Health", under which are included the control and resistance of insect and molluscal vectors and their resistance to insecticides and molluscicides.

Annexes to the report by the director-general give the names of the members of the Organization's International Advisory Committee on Medical Research; details of the meetings of the Organization's Scientific Groups and other research meetings; information about its co-operative research projects and about grants awarded to workers in various countries and the subjects for which the grants were given; as well as information about the Organization's Reference centres and collaborating laboratories in various countries. THE WORLD FEDERATION OF SCIENTIFIC WORKERS

THE *Charter for Scientific Workers and the Constitution of the World Federation of Scientific Workers*, which was formulated soon after the foundation of the Federation in 1946, has now been re-issued in order to make the work of the Federation more widely known*.

The Federation claims to be the only considerable organization promoting co-operation between representatives of both the East and the West which has survived the rigours of the 'cold war'; it now represents more than 200,000 scientific workers in some 30 States.

The *Charter* first affirms the responsibilities of scientific workers: (1) to science, in promoting the integrity of scientific work and resisting the suppression or distortion of scientific knowledge, by full publication of results, co-operation with other scientific workers regardless of racial or national barriers, and by securing the growth of science with due regard to the balance between fundamental and applied science; (2) to the community, by studying the implications of science, by endeavouring to ensure that all knowledge is widely understood and used, and by searching for new ways of utilizing scientific knowledge, especially in fighting famine and disease and in improving conditions of life and work, as well as by studying all aspects of public administration so as to ensure that scientific methods are fully used; (3) to the world, by maintaining the international character of science, by studying the underlying causes of war, by assisting agencies seeking to prevent war, by building stable bases for peace, by working against the diversion of scientific effort in preparation for war, and by resisting movements inspired by anti-scientific ideas. Secondly the *Charter* is concerned with the state of science and scientific workers in securing that science is adequately financed, that results of research are rapidly developed and applied, that research is planned to take into account the intrinsic developments of fundamental science, that the needs of communities are scientifically assessed, and that it is ensured that scientific workers participate actively in the formulation of policy at all levels. Thirdly, the *Charter* is concerned with the opportunities of becoming a scientific worker, including secondary education and university education, and opportunities for part-time studies. Fourthly, it is concerned with facilities for employment of scientists; fifthly, their conditions of work; sixthly, the organization of scientific work, and, finally, the special needs for science in under-developed countries.

Accordingly, the *Constitution* details the aims of the Federation as being to promote understanding and co-operative action between member organizations in assisting it and its constituent members: (*a*) to work towards the fullest utilization of science in promoting peace and welfare of mankind and to ensure especially that it is applied to help solve the urgent problems of the time; (*b*) to promote international co-operation in science and technology, particularly in close collaboration with the United Nations Educational, Scientific, and Cultural Organization; (*c*) to encourage the international exchange of scientific knowledge, and of scientific workers; (*d*) to preserve and encourage the freedom and co-ordination of scientific work both nationally and internationally; (*e*) to encourage improvements in teaching science and to spread as far afield as possible the knowledge of science and its social implications; (*f*) to achieve a closer integration between the natural and social sciences; (*g*) to improve the professional, social, and economic status of scientific workers; (*h*) to encourage scientific workers to take an active part in public affairs, and to make them more conscious of, and more responsive to, the progressive forces at work within society. Membership of the Federation is open to any organization of scientific workers or any group of such organizations in any country, subject to meeting the definitions of scientific workers and qualifications given in the appropriate clause of the *Constitution*.

* *Charter for Scientific Workers and Constitution of the World Federation of Scientific Workers*. Pp. 15. (London: World Federation of Scientific Workers, 1964.)

PROGRESS IN CONCRETE RESEARCH

REFERRING to the activities of the Cement and Concrete Association in his introduction to the report for 1963*, the Hon. Leo Russell, director-general of the Association, stresses particularly the decision of its member companies to increase the income of the Association during that year, made necessary not only by rising costs but also to allow for considered expansion of important projects in the field of concrete research. "Apart from enabling the Association to carry out more effectively the work to which it is already committed, the increased resources will make it possible to undertake some much needed new research and development work".

The report is impressive in its survey of the many research problems and development schemes present in the 1963 programme. In the research section, the subjects include: the constitution of anhydrous cements and cement minerals; reactions in the system CaO—SiO_2—H_2O; cement hydration; problems in chemical analysis;

* Cement and Concrete Association. Report for the year 1963. Pp. 108. (London: Cement and Concrete Association, 1964.)

damping capacity of concrete; concrete strength testing; problems associated with excessively high water/cement ratios; high-strength concrete; fineness of cement; methods of measuring workability. The section on research on the design of structures is noteworthy for its treatment of model testing of structures such as bridges (Manchester Skyway Bridge) and buildings (Metropolitan Cathedral at Liverpool). A further section of the report deals with research on methods of construction. In this connexion: "One of the most interesting experiments recorded . . . is the construction of a length of *B* 6247 in Lancashire as a trial to examine the effects of the omission of expansion joints. Observations and measurements on this project are continuing, but early results suggest that the development of stress in the concrete indicates little difference between sections with and without expansion joints".

The section of the report on information services provided by the Association is fully comprehensive. These include: education; library facilities; publications; liaison with Press, radio and television; films; exhibitions; organized visits; lectures and discussion meetings. In the matter of library facilities, there has been recently issued a *Catalogue of Publications of the Cement and Concrete Association currently available for Distribution in the United Kingdom*†. This is an informative and valuable publication and should be in the possession of all concerned with the Association's literature on cement and concrete. It lists the following titles (among others): advisory booklets and leaflets; prestressed concrete; roads and road bridges; concrete as a material; technical memoranda; library abstracts; translations; Cement and Concrete Association reprints; bound volumes (for sale); research reports. Many of these publications are available for free distribution; those to be purchased are clearly so marked.

Recently, there has also been published an important booklet entitled *The Flexural Strength of Plain Concrete: Its Measurement and Use in Designing Concrete Mixes*, by P. J. F. Wright‡. Fundamentally the thesis here presented is that usually the quality of concrete is judged by its crushing strength, less attention being directed to the functions of tensile and flexural strength. Where failures in concrete roads occur, it is argued, these generally arise from tensile stresses. A critical examination of the flexural strength of concrete has accordingly been made, based on a great deal of small- and large-scale experimental work. Writing in the foreword to this publication, Sir William Glanville, director of road research, says: "A study was first made of methods of testing. This led to the introduction of a British Standard method for flexural testing. Using this standard test, the strength of a range of concrete mixes was investigated. The type of aggregate proved to be important. A section of the paper describes the way in which the data obtained may be used in designing concrete mixes and compares mixes based on compressive and flexural strength requirements". It is pointed out that the use of flexural strength of concrete for specification and control purposes has not as yet been widely adopted in road construction in Britain, but there is little doubt that the data recorded in this paper will be closely examined by highway engineers and others concerned with design and durability, and failures, of concrete roads.

SONIC INVESTIGATIONS ON INTERNAL DAMPING IN SOLIDS

A SYMPOSIUM entitled "Sonic Investigation on Internal Damping in Solids" was held at Imperial College, South Kensington, during August 6–8, 1964. It was organized by the Acoustics Group of the Institute of Physics and the Physical Society, and sixteen speakers contributed papers.

It is some thirteen years since the last symposium on this subject was organized jointly by the Physical Society and the Institute of Metals[1]. The gap of thirteen years, far from representing lack of interest in the subject, rather indicates that papers concerning it are often relevant in other contexts. For example, the International Conference[2] on Crystal Lattice Defects, held in Tokyo in 1962, included seventeen papers on internal damping. In the present symposium, besides measuring techniques, such matters as the influence of third-order elastic constants on apparent internal damping, the effects of microcracks and structural changes on the damping of ceramics and the choice of rubbers for highly efficient shock absorbers were discussed.

In the thirteen years since the last internal damping conference in London, interest has widened in non-metals like quartz, spinels and sapphire, in polymers, and in semiconductors, which at that time were academic curiosities. At that time the role of dislocations in internal damping was only beginning to be understood although it was predicted at that meeting that such damping should possess strongly directional properties and experiment has since verified this. At that time, too, little had been done with frequencies over 20 Mc/s, but now frequencies of 70,000 Mc/s have been used in damping work. These high-frequency waves can now propagate because of the modern development of crystals of very high purity and perfection, such as silicon, germanium and sapphire, which possess so few irregularities that little scattering occurs (except from thermal phonons) even with wavelengths as small as 800 Å. Moreover, in modern high-purity metals, the mean free path of the electrons may be comparable with that of ultrasonic wave-lengths, so that interaction can occur and Fermi surfaces can be delineated. Phonon–phonon interaction, and the interaction of waves with nuclear spin and with electron spin, have only been investigated within the past dozen years. Another development of great potential importance concerns semi-conductors, such as cadmium sulphide, which also possess piezoelectric properties. In single crystals of this substance electrons can be mobilized either by an electric field or by bright light and can increase attenuation, often dramatically. When, however, the electron drift field velocity exceeds that of the ultrasonic waves, in place of attenuation, useful amplification of the ultrasonic wave can occur (see Fig. 47, p. 251, of ref. 8).

A broad outline of the subject was given in the introductory address by Dr. R. W. B. Stephens (Imperial College) and continued by Mr. G. Bradfield (National Physical Laboratory) with emphasis on experimental techniques covering a wide range of frequency, temperature and pressure—from 1/1,000 c/s to many megacycles, from absolute zero to 1,100° C and at pressures up to 1,000 bars. It was stressed that the techniques were diversified not only by these wide conditions but also because of the enormous spread of loss angle values from around unity down to 3×10^{-6} so that an embarrassing variety of equipment is involved. Prof. J. F. W. Bell (Royal Naval College, Greenwich) described a magnetostrictive method of test which would give at least qualitative information at temperatures as high as 2,300° C for both longitudinal and torsional modes.

Internal friction becomes manifest in solids subjected to homogeneous cyclic stress, as in torsional pendulum devices, in standing wave phenomena (as in the resonance of rods or disks) and in travelling wave packets, wide in relation to a wave-length, which progress with only a slight divergence limited by diffraction effects. Joint friction between lumped elements limits accuracy in the first manifestation but, using the second, that is, resonance techniques, a useful degree of accuracy can be obtained even for Q values (π/decrement) as high as 30 million or more, a value for a good crystal of silicon. With travelling waves, however, accuracy is difficult to obtain in such a material for modest frequencies up to, say, 100 Mc/s, for relatively great corrections have to be made for the wave packet divergence and, because multiple end reflexions are used, further large corrections must be made for imperfect specimen-transducer joints and for mode changing at encounter with lateral boundaries. These difficulties (see also ref. 3) were discussed by Dr. M. Redwood (Queen Mary College) together with the consequences of practical imperfections in transmitting and receiving electronics; he also touched on the pulse broadening effects due to frequency-dependent internal damping.

Nevertheless, using these travelling wave techniques, relative values are often useful enough and, as Prof. R. Truell pointed out, some of the difficulties soon disappear at higher frequencies, say, at 1,000 Mc/s where, even in single crystals, the attenuation per centimetre is several decibels so that specimens a few centimetres long are adequate. At these high frequencies (*c.* 4,000 Mc/s) and low temperatures this attenuation constant starts off as a high power (*c.* 4) of the absolute temperature but only increases as a low power (*c.* $\frac{1}{2}$) of the frequency.

Waves in Heavily Absorbing Media

Travelling waves, however, present considerable difficulties with high decrements, around 0·13 or more as in polymers and, for example, in polycrystalline lead. Prof. H. Kolsky (Brown University) described the propagation of a sharp pulse into a viscoelastic solid where both the phase velocity and the attenuation are highly frequency-dependent. A pulse, initially very narrow, soon develops a characteristic shape which broadens linearly with range. He had found[4,5] that waves in polycrystalline lead rods behave somewhat like this, but in these rods not only is the anelasticity frequency-dependent but the stress–strain relation is non-linear. In such materials, in general, the bulk modulus loss angle is only a fraction of the shear modulus loss angle. Prof. Kolsky pointed out that, besides the progressive wave shape change, when a sharp pulse encounters an interface between two bodies matched at one frequency but differing largely in the frequency-dependence of their complex characteristic impedances, very curious wave shapes are reflected.

Mr. M. F. Markham (National Physical Laboratory) pointed out that geometrical path length corrections must be applied to the Kono[6] method of measuring polymer internal damping, using travelling waves encountering a slab obliquely when immersed in a liquid. He agreed with Prof. Kolsky's separation of the real and imaginary parts of the bulk modulus K', K'' from the real and imaginary parts

$$(K' + 4/3G') + i(K'' + 4/3G'')$$

of the modulus involved in travelling longitudinal wave propagation, with the help of the corresponding rigidity modulus components G' and G'', derived from shear wave propagation. He supported Mr. G. Bradfield's suggestion that the partition of waves at interfaces when decrements were in the region of unity or more might have to be calculated by introducing complex characteristic impedances into the Knott equations. However, he avoided such difficulties by using two polymer samples of different thicknesses.

Interaction with Conduction Electrons

Dr. K. Mackinnon described measurements in which electron movement in metals caused absorption of the sound wave; frequencies from 10 to 500 Mc/s were used. In order to achieve adequate interaction the mean free path of the electrons must be of similar magnitude to the sonic wave-length. Single crystals of great purity (*c.* 2 p.p.m.) were used, and the experiments were made at low temperatures to avoid scatter from thermally-induced singularities. Two techniques were used, with and without a magnetic field. In the latter, because the Fermi velocity of the electrons is about 300 times the sound-wave velocity, only electrons moving nearly parallel with the sonic wave-front interacted. Much more interaction occurs using a magnetic field to cause the electrons to orbit with a diameter equal to an integral number of sonic wave-lengths for peak absorption. Thus these maxima appear at equal intervals in the value of the reciprocal field. The absolute value of the absorption need not be known. The orbit properties define the Fermi vector in k space and adjustment of the attitude of the magnetic field vector relative to the crystal axes permits scanning of the Fermi surface and its delineation. Metals such as Cu, Ag, Au and Sn have been thoroughly examined and some features of the zinc and cadmium[7] surfaces are also known. With H. V. Böhm, Dr. Mackinnon had investigated Landau levels in, for example, zinc. The ultrasonic method is often as convenient as the Haas–van Alpen magnetic susceptibility method for obtaining information concerning Fermi surfaces.

Lattice Anharmonicity Effects

Because the non-linearity of lattice forces is related to harmonic generation, and, via phonon–phonon interaction, to attenuation measurements, the extent of this non-linearity can yield information on apparent internal damping. Mr. R. T. Smith (Imperial College) described his method of measurement of the travel times of shear and longitudinal waves passing transversely through a bar under axial compression. The changes in velocity were linearly related to this stress and permitted determination of these third-order elastic constants. For an isotropic polycrystalline solid, only three such constants were needed so that the variation of c_{44}, c_{66} and c_{22} sufficed.

Prof. R. Truell (Brown University), well known for his work on internal damping and wave propagation[8], discussed one of the most spectacular of modern sonic investigations concerning non-linearity of the lattice forces and its influence on the generation of a second harmonic wave. This can build up in amplitude linearly with range as the original wave travels along. The energy in this double-frequency wave must be drawn from the fundamental wave and results in its attenuation, that is, there is apparent, but not necessarily real, internal damping. Indeed, it is possible that thermal loss does not necessarily occur. He described carefully designed electronics at 10–20 Mc/s which permitted the accurate measurement of this second harmonic production. Lattice anharmonicity results in thermal expansion because of thermal waves, and consequent static stress produces second harmonics. Indeed, dislocations can give rise to second harmonics because of their stress fields. Thirdly, the presence of charge carriers can cause second harmonic generation in strongly illuminated materials with both photoelectric and piezoelectric properties, such as cadmium sulphide. In this, in single crystal form, the relative attitudes of the sonic wave vector, the direction of the light and the crystallographic axes markedly influence attenuation. In discussion it was pointed out that subharmonic production was mathematically possible; it had not yet been sought experimentally. It had, however, been demonstrated that lattice anharmonicity could lead to beams at sum and at difference frequencies

originating from the intersection of two strong sonic beams.

Interaction with Charge Carriers in Piezoelectric Solids

Dr. P. D. Southgate (Illinois Institute of Technology) described other investigations on cadmium sulphide at about 225 Mc/s using a drift field to cause sonic wave amplification. He had found that the mobility of charge carriers in it was much lessened by trapping mechanisms, about half of the carriers being affected. The presence of a travelling sonic wave could result in a drift field voltage, and noise modulation could arise on the sonic wave due to the electronic processes which were occurring.

Interaction with Dislocations

Internal damping measurements offer information concerning the nature of dislocation movements, which may be stress-dependent or otherwise. This damping can be at least partially explained in terms of the Granato and Lücke theory (ref. 8, p. 178), while the Bordoni peaks in f.c.c. solids behave broadly in accordance with the built-in kink theory of Brailsford (ref. 8, p. 207), a refinement of the theory of Mason, Seeger *et al.* The Granato–Lücke theory was investigated in work reported by Mr. T. Hinton and Dr. J. G. Rider (Battersea College of Technology), who made damping measurements on a series of lead–indium alloy single crystals (chiefly of 0·05, 0·15, 0·25 and 0·50 per cent In) and on lead–tin alloys, using longitudinal resonance at about 4 kc/s either at room temperature or at about 300° C. Various strain amplitudes were used and the damping was separated into strain-dependent and strain-independent components. The former could be interpreted, over a limited range of composition, to vary as the fourth power, as predicted by the Granato–Lücke theory. The break-away stress on these f.c.c. alloys appears to be 5–100 times below that found by static tests. This is in line with the findings of Hasiguti *et al.*[10] on b.c.c. iron (see, for example, equation 23.11 of ref. 8). The solute-dislocation binding energy was four times that deduced from Cottrell's expression.

Dr. P. D. Southgate (Illinois Institute of Technology) reported on an extension of his previous work[9] on Bordoni peaks in hard crystals of silicon and of magnesium oxide. One set of crystals was cut as tuning forks (100 c/s–600 c/s) and another as bars (100 kc/s in longitudinal resonance). Dislocations were introduced systematically. With these two frequency ranges and damping data up to 1,400° C, the activation energy of the silicon Bordoni processes was established as about 1·6 eV. When the calculated core widths of the kinked dislocation were plotted for copper and silicon at various temperatures, normalized against melting point, silicon had only about a third of the core width of copper although the general shapes of the curves were similar. Comparing activation energies for silicon and indium antimonide, it was interesting to note that these were in the ratio of 2·6 which was roughly the ratio of their electron energy gaps. Magnesium oxide behaved markedly differently from silicon, its decrement being distinctly dependent on strain amplitude. For this (and as found also by Hinton and Rider) the plot of log (strain × decrement) as ordinate against reciprocal strain was not the straight line predicted by Granato and Lücke (see equation 22.1 of ref. 8) but was distinctly concave upwards. α-Quartz is an example of a common single crystal the damping of which has been examined up to 70,000 Mc/s. It is suggested now that this damping is not primarily due to dislocations; much is due to phonon viscosity but some is contributed by ionic impurities trapped during growth. Natural crystals have remarkably uniform damping, but Dr. A. Seed (Standard Telephones and Cables, Ltd.) reported comparisons of synthetic crystals showing that the damping increased about ten-fold with doubling of growth-rate ($\frac{1}{8}$ mm to $\frac{1}{4}$ mm/day). A large damping peak existed at about 60° K which was about 10 times smaller at the lower rate. It was much reduced by X-ray irradiation and was split into two (*c.* 30° K and *c.* 80° K) suggesting that paired ions were responsible. The magnitude was strain-independent. Working in the range 5–100 Mc/s he had established that in accordance with theory, damping should vary in the ratio of shear moduli for various cuts; the BT cut had about twice the damping of AT cut. At room temperature the decrement of both dropped roughly linearly with frequency (*c.* 10^{-6} at 10 Mc/s on AT cut).

Prof. Truell remarked that α-quartz had far more damping than artificial sapphire when the latter is really pure. In discussion it was pointed out that though these were both trigonal crystals, the c_{14} constant of quartz was proportionately greater and this cross-term might affect mode distribution and hence increase phonon–phonon interaction.

Damping in Composite Bodies

Of less fundamental significance, though of great technological importance, were three papers by Dr. J. C. Snowdon, Mr. A. R. Payne and Dr. N. F. Astbury. Dr. Snowdon (Pennsylvania State University) had carefully analysed available damping and elasticity data on natural and synthetic rubbers and allied polymers by the reduced variable method over temperatures mainly from 5° to 35° C, and at frequencies from 1 to 10,000 c/s, and had applied this information in the first instance to the calculation of the efficacy of shock absorbers consisting, for example, of a mass supported by a rubber spring[11]. This exercise appears to show that the interaction between damping peak width and the inevitable relation of modulus drop to temperature imposed an upper limit on shock absorber efficacy whatever composition of rubber was tried; some slight improvements could be obtained with paralleled springs of differing composition, and with more complex mechanical structures. Mr. Payne (Natural Rubber Producers Research Association) reported on rubber damping and elasticity. He had found that, with a certain proportion of filler, such as carbon black, the damping was little affected by the nature of the rubber. Indeed, in certain circumstances, the rubber could be replaced by a paraffin liquid, the system retaining similar dynamic damping, and apparent elasticity and anelasticity, and some similarity of strain dependence. He thought, as did Dr. Snowdon, that the need was now not so much for new polymers for such things as tyres and shock absorbers, as for improved methods of dispersing filler in binder and achieving chemical bonding.

Dr. Astbury (British Ceramic Research Association) reported on work carried out at the British Ceramic Research Association[12]. The investigation of the sintering process covered widely different materials—brick, domestic and bone 'china', porcelain (including electrical insulation) and sintered alumina; the loss angles varied from 0·01 to 10^{-5}. The damping varies nearly linearly with pore volume but is nearly invariant with frequency. One type of ceramic which is clay-based acts like a crystalline phase in a glassy phase with pores up to 20 per cent of volume; devitrified glass is similar but without the pores, and fine 'china' porcelain would be mainly vitreous with perhaps 5 per cent of closed pores. There seem to be fine cracks, especially around the pores, and these seem to be responsible for a great deal of the damping; structural changes occurring during damping–temperature runs, however, such as the α-β-cristobalite change at 100°–200° C and the α-quartz change at *c.* 570° C, are reflected in fluctuations in both damping and elasticity. In discussion it was suggested that the great volume change in the former might react with the micro-crack system to give damping peaks. An important problem concerns the desirability of internal damping in ceramics to reduce the risk of fracture from shock waves.

In the symposium as a whole the damping of rocks to earthquake waves (< 1 c/s) and to seismic exploration waves (10–150 c/s) was not discussed, and little was said about frequencies of 5,000 Mc/s and upwards. Little emerged in discussion concerning equipment design and techniques, although no doubt useful interchanges of information occurred privately. Little common ground is shared between workers on metals and hard single crystals on one hand, dealing with loss angles down to 3×10^{-8}, and workers on polymers dealing with loss angles of 0·1–1·2 radians. Even so, an occasional symposium, in which such widely diverse fields of interest are included, serves a useful purpose. G. BRADFIELD

TENTATIVE CLASSIFICATION OF FOOD IRRADIATION PROCESSES WITH MICROBIOLOGICAL OBJECTIVES

WE were recently asked, as members of an expert group, to define the main types of irradiation process applied to foods for microbiological reasons, and to suggest names for the types recognized. This article briefly records our joint conclusions.

With any kind of process for the preservation of food, two different broad microbiological objectives can be distinguished. In the first, the aim is to kill all micro-organisms of significance in the food, and, where achieved by heating, the process is commonly called sterilization, though a few micro-organisms may remain alive but quiescent; this is the condition well known to food technologists as 'commercial sterility'. For this type of heating process, the French have a special name *appertization*, commemorating Nicolas Appert, who invented it. The second broad objective is to kill many, but by no means all, of the micro-organisms. When achieved by heating, this is called pasteurization; it may be done either to kill pathogenic organisms in particular, or to reduce the number of viable micro-organisms generally and so improve keeping quality.

The same broad division of objectives applies to irradiation, so that hitherto radiation processes have commonly been separated, from the microbiological point of view, into radiation sterilization and radiation pasteurization. However, we did not regard this classification as adequate, or these terms as very suitable.

Sterilization is at best an abstract concept, which cannot be verified experimentally over any sizable number of packages, and special difficulties arise with an irradiation process. While viruses are comparatively easily killed by heat, such killing cannot be guaranteed with any process of irradiation alone, under conditions practicable with foods. Consequently sterilization, in the commonly understood sense of producing almost complete absence of viable micro-organisms, cannot be reliably achieved with radiation at present.

Pasteurization, again, is normally understood to kill most viruses, but this certainly cannot be achieved with the relevant doses of radiation. Moreover, as was pointed out at the European Meeting on the Microbiology of Irradiated Foods (F.A.O./I.A.M.S., Paris 1960 (ref. 1)), in the case of radiation treatment the term pasteurization is undesirably ambiguous, being used to describe processes with two distinct aims, one aim concerned with public health and the other not, which in some countries would require different legislative treatments. Even with heat processing, a different term is needed: for example, milk for cheese-making is sometimes heated to diminish its population of micro-organisms, but the heat treatment is less severe than that defined as pasteurization; the need for a term to describe this procedure has been plain for ten years, and was recognized by the International Dairy Federation, which provisionally proposed the word *thermization*.

We therefore suggest the following working definitions for the main types of irradiation treatment intended to kill micro-organisms in foods:

Sterilization by irradiation would be the application to foods of doses of ionizing radiation which produce sterility, that is, total absence of all viable micro-organisms as determined by any known method. This state cannot at present be guaranteed with any radiation process practicable with foods.

Among the attainable microbiological objectives, we recognized three types distinguished according to objective, and defined as follows:

Type I is the application to foods of doses of ionizing radiation sufficient to reduce the number and/or activity of viable organisms to such an extent that very few, if any, are detectable in the treated food by any recognized method (viruses being excepted) while no spoilage or toxicity of microbial origin is detectable no matter how long or under what conditions the food is stored in the absence of recontamination.

Type II is the application to foods of doses of ionizing radiation sufficient to reduce the number of viable specific non-spore-forming pathogenic micro-organisms (other than viruses) so that none is detectable in the treated food by any standard method.

Type III is the application to foods of doses of ionizing radiation sufficient to enhance keeping quality by causing substantial reduction in the numbers of viable specific spoilage micro-organisms.

It will be evident that *sterilization by irradiation* and *Type I* treatments have both been indiscriminately covered by the term radiation sterilization, while radiation pasteurization also has covered treatments of both *Types II* and *III*.

The following are the names we suggest for these types of treatment: *Type I, radappertization*; *Type II, radicidation*; *Type III, radurization*; and the reasons for these suggestions are given as follows.

The prefix *rad-* or *radi-* stands for the radiation used. (Lat. *radiare*, to shine). We could not think of any term which would indicate more precisely what kinds of

radiation are intended. The prefix *gamma* is too restrictive, excluding types of radiation which might be used. The form *radio-* promotes confusion with Hertzian waves. Terms like *cold pasteurization* may lead to confusion with different means, other than heat, of attaining the same objectives.

The aim of *radappertization* is just the same as that of appertization, to produce the condition of *commercial sterility*. With the prefix *rad-*, there is an almost exact description of the *Type I* process. Appertization has always been understood to imply a heat treatment, but the prefix *rad-* clearly discounts this. There is the inconvenience that English-speaking bacteriologists, not aware of the work of Nicolas Appert, are not yet accustomed to use the word appertization. We consider, nevertheless, that the aptness of the term radappertization far outweighs these objections.

The term *radicidation* derives from Lat. *radiare*, to shine, and *occidere*, to kill. The common use of the root *-cide* in words like germicide and bactericide has given it a more general connotation than would be desirable here, where the implication is towards some particular species. Hence, the specificity of aim implied in *Type II* treatments is not apparent in the term radicidation; and the best solution seems to be the usage, for example *Salmonella* radicidation, as one might say *Salmonella* disinfection. Further, radicidation bears misleading resemblance to radical, radish, etc., derived from Lat. *radix*, root. An alternative variation, radioccidation, is rejected because of written resemblance to radio and spoken resemblance to oxidation, besides possible confusion with Occident. Another alternative, irracidation, derived from *irradiation* and the root *-cide*, does not evidently contain the root *rad-*; and has the further inconvenience of seeming to entail an unnecessary prefix of ir- to the corresponding terms radappertization and radurization.

Radurization, based on *rad-* plus Lat. *durare*, to last or endure, expresses well the aim of the *Type III* process, to make the food more stable by means of radiation. The obvious defect of this term is that it does not indicate any connexion with microbiology. Further, it seems to verge on barbarism when rendered into French.

We submit that the foregoing classification of types of radiation treatment is logical; and adequate, for the present, because it seems premature to try to deal now with conceivable but as yet ill-defined combinations of radiation with, for example, heat or chemical preservatives.

As regards the terms we have suggested to designate the main types of treatment, however, we do not claim that they are anything more than the best we can suggest. We shall be interested to hear further suggestions.

VARIABILITY OF THE STRONTIUM-90 AND CÆSIUM-137 BURDEN OF NATIVE PLANTS AND ANIMALS

By L. L. EBERHARDT

Biology Laboratory, Hanford Laboratories, General Electric Company, Richland, Washington

KNOWLEDGE of the inherent variability of radionuclide burdens of plants and animals is obviously of considerable importance in planning any kind of radiological survey of such populations, whether for research or health-protection purposes. A potentially important additional feature of such knowledge is the prospect of making some inferences about the manner in which radionuclides may be distributed over the landscape, which in turn may have a direct bearing on the course of such materials through a food web and, in extreme circumstances, on the radiation exposure of individual items of the biota.

The work recorded here is primarily concerned with materials originating in world-wide fall-out, and is restricted to the biologically important, long-lived nuclides strontium-90 and cæsium-137 (half-life approximately 30 years). Two sources of data, the Nevada Test Site and National Reactor Test Site (Idaho), receive radionuclides of local origin, but no attempt will be made here to evaluate the relative importance of contributions of local and world-wide origin. Only data on native plants and animals have been used here, principally to avoid uncertainties about origin of domestic animal food supplies, and 'pooling' of samples from large areas.

Where possible, I have used only records obtained over relatively short-time intervals on areas of restricted size.

It is generally accepted that the bulk of world-wide fall-out is brought to the ground by precipitation, and it thus seems logical that variation in the local distribution of precipitation will contribute heavily to the variability of radionuclide deposition. The intensity of rainfall may influence radionuclide deposition[1], and presumably features of topography and wind direction and force will have important local effects on physical deposition.

Radionuclide burden of vegetation may be influenced by plant phenology, in regard to the season and duration of exposure relative to periods of maximum precipitation, and by surface characteristics of leaves and stems[2]. Very likely density of the stand of vegetation and the prospects for overlayering or stratification may also have a bearing

on local variation in exposure to radionuclides, but these factors do not seem to have been investigated in any detail so far.

Animal food habits are clearly important in determining uptake of radionuclides. Seasonal changes in food sources can also be expected to interact with the factors determining radionuclide burden of vegetation to influence both levels and variability. On a local scale, evidently the size of 'home range' or 'cruising radius' of individual animals may be of importance in the sense that accumulation of biologically active (that is, metabolized) radionuclides by animals may be regarded as some sort of averaging or integrating process in time.

Many more factors presumably affecting variation in radionuclide burden may have been demonstrated, or might be proposed, but the purpose of the present report is to present a measure of variability. Much additional attention to details of mechanism and form seems important, but largely beyond the scope of presently available data and knowledge.

The coefficient of variation (standard deviation divided by mean) is used as a measure of variability here. Choice of this measure has been predicated in part on the results, that is, on the fact that the coefficient of variation seems to hold constant over a relatively wide range of mean concentrations of radionuclides, and in part on the form of the available records. Nearly all the data examined here are limited to very small samples in any one area or time-period, usually ranging between three and ten radionuclide determinations per set. Such small samples pose technical statistical difficulties in characterizing variability (for example, form of the distribution function, utility of the higher sample moments, weighting, etc.). I have arbitrarily elected to compute a coefficient of variation for each sample, and to combine the coefficients by weighting by sample size. Justification for the procedure lies largely in the empirical observation that plots of individual coefficients against the means show no evidence of trend in the data used here.

The utility of the coefficient of variation lies in its being a 'dimensionless' measure (expressed as a ratio or percentage), thus permitting comparisons over a wide range of materials, and the ready calculation of sample sizes required for relative precision in designing a sampling survey.

Coefficients of variation for burdens of strontium-90 and cæsium-137 (Table 1) are surprisingly consistent over a wide range of plants and animals. Values for strontium-90 range from about 0·30 to 0·45, while those for cæsium-137 appear somewhat lower, ranging roughly from 0·25 to 0·35. Various factors possibly affecting individual sets of data are indicated in notes appended to Table 1. With one exception (Maryland white-tailed deer), the bone–strontium-90 values were calculated in terms of picocuries (10^{-12} c.) per g calcium (strontium units). Analysis of the Alaskan caribou data in terms of picocuries per g standard dry weight yields virtually the same coefficient of variation. The plant data were calculated on the standard dry weight basis, while soil-levels were on a unit area basis. All cæsium-137 values were expressed in units per g dry weight.

The influence of analytical technique on these values is difficult to appraise, since the data come from a number of different sources. Presumably sample mass, length of counts, detection system, chemical processing, and other factors involved in analysis for radionuclides could contribute substantially to the observed variability. Appraisal of variation due to analytical technique for the caribou muscle content of cæsium-137 is possible, since most of the samples were run in duplicate or triplicate, starting with nearly equal masses (about 1,200 g) of muscle tissue from individual animals. Average 'within-sample' coefficients of variation for 34 duplicate and 32 triplicate caribou muscle samples were 0·04 (in both sets), suggesting a relatively small contribution due to technique for our data. A similar calculation on 42 duplicate strontium-90 in soil[3] yields a coefficient of variation of 0·05, again indicating a minor contribution from technique. Five 'blind duplicates' on strontium-90 in deer bones[4] yield a coefficient of variation of 0·06.

Table 1. COEFFICIENTS OF VARIATION FOR STRONTIUM-90 AND CAESIUM-137

Area	Organism	Total sample size	Coefficient of variation	Sampling period	Notes	Ref.
		Strontium-90 in bone				
Alaska	Caribou	57	0·47	Month	*a*	6
Idaho	Jackrabbits	87	0·30	Year	*b*	5
	Antelope	41	0·41	Year	*b*	5
	Deer and elk	28	0·44	Year	*b*	5
	Coyote	42	0·44	Year	*b*	5
Nevada and Utah	Jackrabbits	43	0·45	Month	*c*	7
	Jackrabbits	57	0·30	Day	*d*	7
	Jackrabbits	222	0·32	Year	*e*	7
California	Black-tailed deer	36	0·34	Year	*f*	4
Maryland	White-tailed deer	67	0·26	Month	*g*	8
		Strontium-90 in plants				
Alaska	Lichens	18	0·34	Month	*a*	6
	Sedges	25	0·25	Month	*a*	6
	Willows	10	0·30	Month	*a*	6
	Caribou rumen contents	53	0·28	Month	*a*	6
		Strontium-90 in soil				
Nevada		367	0·20	—	*h*	7
'World-wide'		32	0·24	—	*i*	3
		Cæsium-137 in muscle tissue				
Alaska	Caribou	59	0·36	Two weeks	*j*	9
		Cæsium-137 in plants				
Alaska	Lichens	56	0·22	Day	*k*	10
	Sedges	66	0·30	Day	*k*	10
	Willow	35	0·26	Day	*k*	10
	Caribou rumen content	55	0·24	Two weeks	*k*	9

a, Caribou were collected in the general area bounded by Kotzebue, Point Hope, and Anaktuvuk Pass (in the Brooks Range), all above the Arctic Circle, in 1960 and 1961. Plants were collected in the Cape Thompson area in summers of 1959, 1960, and 1961. *b*, Data on jackrabbits used here are those given for the Taber area (Table 2 of the reference), which is cited (p. 457) as an 'offsite control station'. Data for the other species are that of Table 1 in the reference, and source of the samples is described on p. 455. *c*, Data are from Table 1 of the reference, and are for an area 13 miles from the Nevada Test Site, established as a 'close-in fall-out area' (p. 45). *d*, Data are from Table 2 of the reference, and are for an area '99 miles from Ground Zero at the Nevada Test Site'. Only those collections indicated as having been made on a single day are used here. Inclusion of two additional samples (from Table 2), identified as 'May, 1960' and 'May, 1961' increases the average coefficient of variation to 0·46 for this area. *e*, Data are from Table 3 of the reference, and are for a sequence of distances from the Nevada Test Site, ranging from 0 to 432 miles. Dates are given only as '1958' and '1959'; but the small collections at each of the 18 sites may well have been made on single days. There seems to be no indication of a trend in magnitude of the coefficient of variation with distance from the Test Site. *f*, Data are those of Table 1 of the reference, grouped into periods approximately one year in length, starting with 1954. Individual animals ranged in age from 13 to 24 months. *g*, Coefficients of variation were computed from data arranged by age-class and would presumably be somewhat larger if age (to the year) had not thus been excluded from consideration. The value for the 13–20 month class is 0·32, very nearly that given for black-tailed deer of the same age-group. *h*, Data from Tables 1, 3, and 4 of the reference cited. *i*, Data from Tables *A* and *B* of the reference cited. Coefficients of variation were calculated for the replicate locations labelled '*A*' and '*B*' at each site, thus pertaining to 'within-site' variability. Weighted value multiplied by $\sqrt{2}$ to adjust for use of replicate samples at each subsite. *j*, Data were retabulated for two-week collecting periods within a given river drainage or other restricted area. All caribou records used in this article are from essentially the same set of animals. *k*, Data are essentially those of the references cited, but were regrouped in varying degree in the computations used here, and stem from an analysis for design of later samplings.

The results reported here should not be interpreted as meaning that the coefficient of variation for levels of these two radionuclides is everywhere roughly constant. Calculations covering large areas yield appreciably higher values, as would be expected on the basis of real differences in radionuclide levels over large areas or time-periods. Relative variability increases rapidly as levels approach 'detection limits', or 'background' counts. Further, extensive data on jackrabbit bone strontium-90 levels in the vicinity of chemical processing plants[5] yield many coefficients of variation well over unity.

I have been unable to locate data on cæsium-137 analysis of sizable samples of native plants and animals other than the Alaskan data reported here. Limited data from the state of Washington obtained in a present investigation of fall-out in natural ecosystems suggest very much the same values as those obtained from the Alaskan data.

Rather larger samples than are now available appear desirable for making satisfactory inferences about the actual form of the distribution of radionuclide burdens in individual plant and animal samples. The observed relative constancy of the coefficient of variation does, however, suggest that the logarithmic transformation may be suitable for statistical analysis of such data.

This work was performed under contract *AT*(45–1)–1350 between the U.S. Atomic Energy Commission and the General Electric Co.

RADIUM-226 IN DIET AND HUMAN BONE FROM SAN JUAN, PUERTO RICO

By NAOMI A. HALLDEN and Dr. JOHN H. HARLEY
Health and Safety Laboratory, U.S. Atomic Energy Commission, New York

THE relationship reported here between radium-226 in the diet and radium-226 appearing in the bone of Puerto Ricans is particularly interesting, since the daily radium intake is a factor of three lower and the calcium intake is a factor of two lower than that of a standard Western diet.

For the past few years the Health and Safety Laboratory has been performing measurements to enlarge our knowledge of the natural activity levels in the biosphere. This programme is pertinent because man is most likely in equilibrium with this environmental activity, whereas this is not true of the artificially produced radionuclides, such as strontium-90, from radioactive fall-out. An understanding of the equilibrium situation may very well shed considerable light on non-equilibrium situations, for example, where the relationship between diet and bone levels of strontium-90 is sought.

In 1963 this Laboratory performed analyses for radium-226 on samples of diet and human bone collected in our tri-city diet programme[1]. The average dietary intakes in New York, Chicago and San Francisco were found to be 2·3, 2·1 and 1·7 pc. ^{226}Ra/day. Since the average calcium intake in these cities is 1·05 g/day[2] the radium intake may be expressed as 2·2, 2·0 and 1·6 pc. ^{226}Ra/g calcium, respectively. The corresponding human bone levels were found to be 0·032, 0·031 and 0·026 pc. ^{226}Ra/g calcium. This implies a rather uniform observed ratio[3] between the radium to calcium ratio in bone to that in the diet of about 0·015.

In this present work, two Puerto Rican diet samplings, spaced one year apart, were obtained for the Health and Safety Laboratory's ^{90}Sr programme. Samples of human vertebræ were also obtained from Puerto Rico as part of the same programme.

In all cases, the individuals were living in San Juan for a few years before their deaths and are known to have been lifetime residents of Puerto Rico. Their ages at death ranged from 15 to 60 years. The individuals in this investigation were all in an extremely low income group. The calcium intake is approximately a factor of two lower than that typical of the continental United States. Also, the calcium contribution from milk is about 35 per cent as contrasted to 60 per cent for the urban United States.

The radiochemical determination of ^{226}Ra in human bone and in vegetation samples has been reported in detail elsewhere[4,5]. In brief, for human bone, 10 g of ashed vertebræ, barium carrier, and ^{133}Ba tracer for recovery were dissolved in hydrochloric acid, and $RaBaSO_4$ was precipitated in buffered medium. After centrifuging and decanting, the $RaBaSO_4$ precipitate was dissolved in alkaline tetra-sodium EDTA. Radium was determined by an emanation technique[5], where the gaseous daughter ^{222}Rn was counted overnight in a 2-l. ion chamber. In these chambers 1 pc. ^{222}Rn yields 225 c.p.h. and the backgrounds for eight different chambers range from 6 to 10 c.p.h.

The radium blank for reagents used in this bone procedure is 0·02 pc. The average recovery of the twenty-seven Puerto Rican bone samples based on the ^{133}Ba tracer yield was 97 per cent, while eighteen test samples with added radium gave 94 per cent recovery.

Radium and barium in the Puerto Rican vegetation samples were isolated as chromates as part of the procedure for determination of ^{90}Sr in these same samples. The barium chromate precipitate was dissolved in dilute perchloric acid and radium again measured by the emanation technique. Recovery of radium from these Puerto Rican vegetation samples was determined radiometrically from ^{85}Sr tracer yield data on each sample. The ratio of ^{85}Sr and ^{133}Ba yields from twelve experimental vegetation samples was 1·00 ± 0·08, so the ^{85}Sr is an adequate tracer.

The results for the two Puerto Rican diet surveys are shown in Table 1 in terms of pc. ^{226}Ra/kg of original material. Based on average consumption figures compiled by

Table 1. Radium-226 Content of Puerto Rican Diet Samples

Category	Items in composite	Dietary intake (kg/yr.)	Content of original material (pc. ^{226}Ra/kg)			
			g Ca/yr.	Survey I (Jan. 1962)	Survey II (Jan. 1963)	Average ^{226}Ra consumed per year (pc.)
Dairy products	Liquid milk	68	66·6	0·15	0·08	7
Rice	Rice	65	52·6	—	0·28	18
Beans	Beans	22	22·2	2·74	0·83	40
Codfish	Codfish	10	9·1	0·31	0·61	5
Viands	Plantains, bananas, yautia	55	9·9	1·81	2·46	118
Other vegetables	Pumpkins, onions	6	2·6	0·76	1·22	6
Fruits	Mangos, oranges, guanabana, mamey	25	5·8	0·83	0·67	19
Bakery products	Bread	20	16·2	1·86	1·49	34
Water		400 litres	—	0·007	0·007	3
Total			185 g Ca/yr.			250 pc./yr.

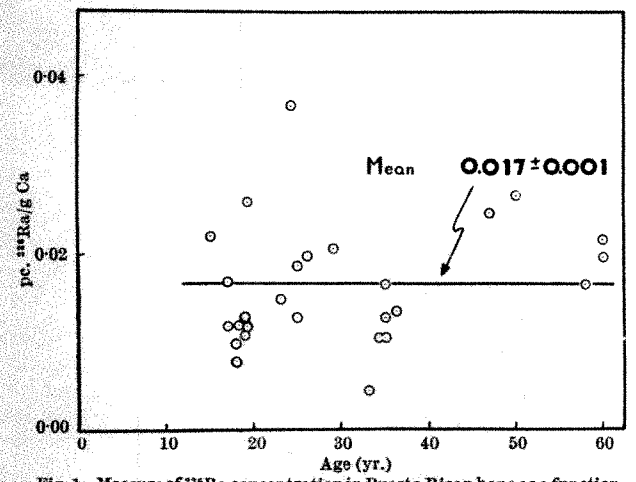

Fig. 1. Measure of ^{226}Ra concentration in Puerto Rican bone as a function of age. The solid line is drawn through the mean of all data

J. Rivera of this Laboratory, after consultation with scientists from the University of Puerto Rico and the Department of Agriculture of the Commonwealth of Puerto Rico, these results may be converted to quantity of ^{226}Ra consumed per year. This is also tabulated in Table 1. The calcium intake of people living on this diet was estimated from calcium measurements made on the ash from these samples[6] and is 185 g per year.

The results for the human bone samples are plotted in Fig. 1 as a function of age. In order to compute the value pc. ^{226}Ra/g calcium from the measured value pc. ^{226}Ra/g of bone ash, the mean value 0·037 ± 0·02 g calcium per g of ash was used. It has been determined in this Laboratory from some 115 samples that this factor is constant with age and the error in using this mean value is slight.

The mean ^{226}Ra content of Puerto Rican human bone and the standard deviation of the mean is seen from these data to be 0·017 ± 0·001 pc./g of calcium. This value is to be compared with the dietary intake computed from Table 1 of 1·35 pc. ^{226}Ra/g calcium. From these measured bone and diet values an observed ratio can be computed for Puerto Rico of 0·013, which compares quite well with observed ratios already noted in New York, Chicago and San Francisco of 0·015, 0·016 and 0·016.

This study shows that individuals on a low-milk, low-calcium diet exhibit the same bone to diet radium–calcium ratio (*O.R.*) as those on a 'normal' Western diet. The maintenance of the *O.R.* over such widely differing radium and calcium intakes indicates that the uptake of radium in the human skeleton may be controlled by the dietary calcium intake.

We thank Isabel M. Fisenne and Salvatore Garafalo for performing the chemical separations and Helen W. Keller for the radon measurements.

ROTATIONAL STRUCTURE IN THE CHEMILUMINESCENCE SPECTRUM OF MOLECULAR OXYGEN IN AQUEOUS SYSTEMS

By Dr. A. U. KHAN and Prof. M. KASHA
Institute of Molecular Biophysics and Department of Chemistry, Florida State University, Tallahassee, Florida

MOLECULAR oxygen was identified, in a previous communication[1], as the origin of the red chemiluminescence observed in the reaction of hydrogen peroxide with OCl^- (or Cl^2) in alkaline solution, following earlier work of Seliger[2] and others. Our observations of a second very strong narrow band in the chemiluminescence spectrum permitted the correlation of the observed 1567 cm^{-1} spacing with the vibrational frequency of ground state oxygen. Considering two alternative interpretations, we tentatively assigned the bands to the $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ transition of O_2, displaced to higher frequency by solvent interaction. Several additional investigations have been published in the meantime, broadening the observations and their possible interpretation[3–6].

Because this chemiluminescence reaction is a vigorous, heterogeneous reaction, and especially because, as Ogryzlo *et al.*[4] have shown, a whole series of different O_2 electronic transitions is involved in the chemiluminescence spectrum, it is of interest to learn which transitions could possibly originate from solvated oxygen species, and which from gaseous oxygen. The hydrogen peroxide reactant is solvated, the reaction intermediate[7] O—O—Cl^- is also solvated, and yet ultimately the end-product is ground-state O_2 in the gaseous state. We have undertaken spectroscopic investigations at higher resolution in order to gain more detailed information on this problem.

In our new experiments a special externally silvered flow cell was used, permitting continuous bubbling of tank chlorine, through a vertically oriented sintered glass filter, mounted behind a 'Pyrex' observation window, into flowing 0° C alkaline 10 per cent hydrogen peroxide. Since we were determined to investigate the fine structure of extremely faint bands at moderate spectroscopic resolution, precautions were taken for very long periods of operation (3–5 h). The Steinheil 'Universal' spectrograph *GH*, with 3 large glass prisms, and with 640/650 mm collimator/camera *f*/10 optics in an infra-red setting was used, yielding a dispersion of approximately 41 Å per mm in the region of 7000 Å. This arrangement, which was adequate to reveal rotational fine structure in glow discharge spectra of O_2 gas, was used in all the experiments reported. Eastman *I–N* water hypersensitized infra-red spectroscopic plates, sensitive to approximately 9000 Å, were used throughout.

The $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ emission in gaseous O_2, first observed by Kaplan[8], was examined (0–0 band) at high resolution by Branscomb[9]. His analysis indicated that, although the pure Q branch is missing as expected for this case, nevertheless R_Q and P_Q branches accompany the R and P branches, respectively, in a fashion characteristic of spin-intercombinations. A definite gap in each vibration–rotation band can then be expected as a prominent feature at moderate resolution, between the R, R_Q, and P, P_Q band systems. Krishna and Llewellyn in this laboratory have investigated the *RF* electrodeless glow discharge spectrum of gaseous oxygen at moderate resolution[10], and have observed the strong 0–0 band and the much weaker 0–1 band of the $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ transition. Their

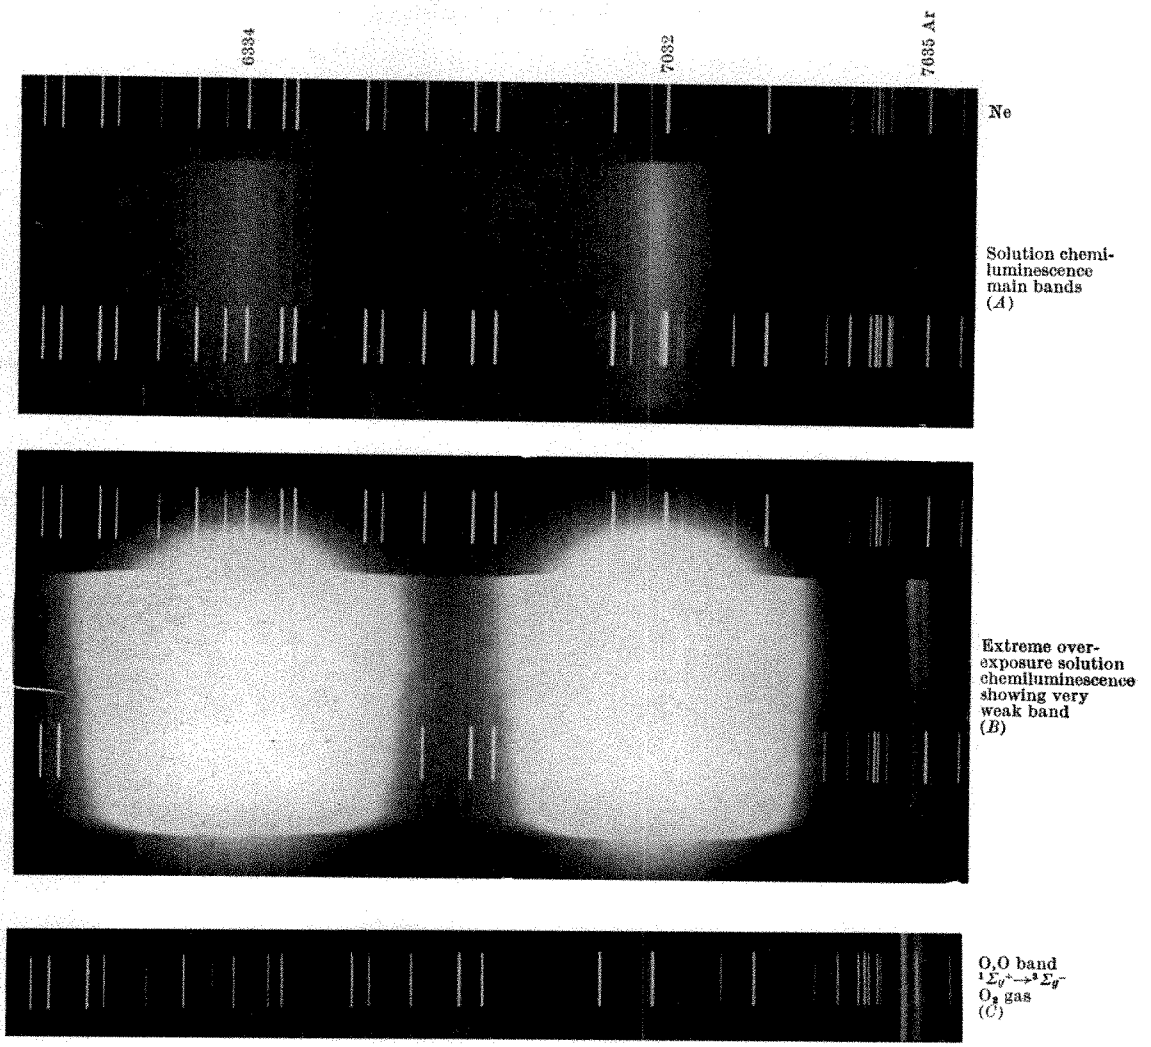

Fig. 1. Chemiluminescence spectra at higher spectral resolution for the reaction of alkaline hydrogen peroxide with chlorine, compared with *RF* electrodeless discharge spectrum of gaseous oxygen (after Krishna and Llewellyn[16]). *A*, slit 0·25 mm, exposure 5 min; *B*, slit 0·50 mm, exposure 5 h; *C*, slit 0·25 mm

plates show partially resolved rotational structure (rotational band flutings are clearly visible on the original plates), with a pronounced gap in each band. A print of one of their plates for the 0–0 band is shown in Fig. 1*C*.

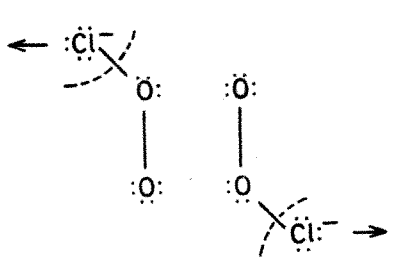
The solution chemiluminescence main bands (H_2O_2 + Cl_2 reaction), which we previously reported[1] at 6334 Å and 7032 Å at low resolution, are shown in a weak exposure (5 min) in Fig. 1*A* at moderate resolution. There is no suggestion of any fine structure or unsymmetrical band contour in the observed diffuse bands; at 50 per cent plate blackening the bands appear much broader and represent their actual half-width more accurately, because of this more nearly linear response region of the plate. The diffuseness and anomalous relative intensity of these bands require a special interpretation, which we shall discuss later.

In a few somewhat strenuous experiments, extreme over-exposures of the chemiluminescence spectrum were photographed. This required 5 h of continuous bubbling of chlorine, wider spectrograph slits, and careful maximization of the optical arrangement. The typical spectrum is shown in Fig. 1*B*. The main chemiluminescence bands are now seen as extremely broad regions of emission. But the (strongest) weak band previously noted by us, and observed more extensively by Browne and Ogryzlo[4], is now seen to reveal definite rotational structure, and to coincide perfectly with the 0–0 band of the $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ transition of gaseous O_2, investigated by Krishna and Llewellyn[16]. (As noted in the legend of Fig. 1, the slit used for the solution chemiluminescence was twice that used in the gas discharge experiment, but the rotational gap is still clear; curvature of the slit image at the top end of the band is the result of our collimator focus setting.) The results described require the unique interpretation that the band system observed near 7635 Å originates from $^1\Sigma_g^+$ excited O_2 trapped inside a gas bubble. That a very small fraction of the O_2 molecules produced could emit light as gaseous O_2 is not surprising. Browne and Ogryzlo reported 0–0, 1–1 and 0–1 bands for the $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ transition and 1–0 and 0–0 bands for the $^1\Delta_g \rightarrow {}^3\Sigma_g^-$ transition of oxygen; we believe that all these extremely weak bands originate from gaseous oxygen from within the bubbles during (or after) the chemiluminescence reaction (also assumed by Browne and Ogryzlo). Higher resolution investigations should reveal structure in all of these bands.

The observed diffuseness of the main chemiluminescence bands, and their occurrence at 6334 Å and 7032 Å, requires consideration of several alternative interpretations:

(1) The bands may represent the $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ transition in hydrated O_2, shifted by 2,593 cm^{-1} to higher frequency by the solvent interaction.

(2) The bands may represent the superposition of quantum states[11] transition $2(^1\Delta_g) \rightarrow 2(^3\Sigma_g^-)$ brought



about directly by the interaction of two $^1\Delta_g$ excited O_2 molecules in the gas phase.

(3) The bands may represent the superposition of quantum states transition $2(^1\Delta_g) \rightarrow 2(^3\Sigma_g^-)$ brought about indirectly by the interaction of two Cl—O—O⁻ intermediates in solution, with emission from the solvated O_2 collision pair, and assuming negligible solvation shift.

Concerning case (1), our present experiment leaves room for a solvent-displaced $^1\Sigma_g^+ \rightarrow {}^3\Sigma_g^-$ transition to occur, since the bands reported by Ogryzlo *et al.*[4] for this transition are clearly for excited O_2 gas in the bubbles. The fact that Arnold, Ogryzlo and Witzke were able to observe very weak bands at 6340 Å and 7030 Å in electrical discharge also in gaseous oxygen still leaves some doubt because of the possibility of minute traces of water in such systems[12]. Griffith's crystal field calculations[6] for hydration of oxygen indicate that exactly such a high frequency shift could be found as suggested by this interpretation case; moreover, the $^1\Delta_g$ state is shifted downward in energy by the crystal field interaction, which could account for its non-observation as a hydrated species. A decisive experiment needed here is to observe the $^1\Sigma_g^+ \leftarrow {}^3\Sigma_g^-$ absorption of O_2 in water solution. Because of the extreme forbiddenness of this transition, a high-pressure, long-path experiment is essential.

Concerning case (2), it was proposed by Stauff and Schmidkunz[13] that the combination or superposition transition proposed for certain absorption bands in liquid oxygen by Ellis and Kneser[11] could account for the chemiluminescence band at 6334 Å because of the obvious coincidence of wave-length with the 0–0 band of the $2(^1\Delta_g) \rightarrow 2(^3\Sigma_g^-)$ absorption in liquid oxygen. Ogryzlo *et al.*[4] also favour this interpretation. Although these superposition bands have been referred to as "O_4 bands" no stable complex is required by the transition mechanism. We are inclined to reject this interpretation involving the direct interaction of two singlet excited gaseous oxygen molecules, liberated by the primary chemiluminescence reaction and emitting from within the gas bubbles. We would expect more single-molecule emission. (The relative yield of $^1\Delta_g \rightarrow {}^3\Sigma_g^-$ is undetermined, but may be large[4].) However, the $^1\Sigma_g^+$ and $^1\Delta_g$ states are highly metastable, and the enhanced probability of the superposition transitions could account for the dominating observability of the proposed $2(^1\Delta_g) \rightarrow 2(^3\Sigma_g^-)$ transition. An absolute quantum yield determination for the overall chemiluminescent reaction could assist in securing this interpretation. We are not certain what rotational structure should be expected for O_2 pairs, or weak O_4 complexes, but the diffuseness and broadness of the two main chemiluminscence bands argues against a gas phase emission.

Case (3) is a modification of case (2) which we believe is more in accord with the mechanism of the primary reaction[7]. We consider that the (ground-state) intermediate Cl—O—O⁻ may be relatively stable toward solvent chemical interaction, but is highly unstable toward reaction with another Cl—O—O⁻. We next picture the vigorous elimination, on collision of intermediates, of two Cl ions simultaneously, leaving (perforce) two singlet oxygens in collisional proximity:

Thus, emission of combination or superposition transition would be favoured over single molecule singlet → triplet emission. This could account for the apparent dominance of the superposition transitions, but then one would expect not only the emission from the $2(^1\Delta_g)$ states, but also from the $2(^1\Sigma_g^+)$ and $(^1\Sigma_g^+ + {}^1\Delta_g)$ states[11,14,15]. Perhaps the failure to observe these additional combination or superposition bands is an argument against case 3 (and case 2) as possibilities. Ogryzlo and co-workers have assumed that the greater 'quenching' of the $^1\Sigma_g^+$ state of gaseous O_2 by H_2O molecules favoured the formation of $2(^1\Delta_g)$ states of collision pairs of O_2 over other combination states. This suggestion could apply equally well to case 3, especially because we assume all events take place in the liquid phase. Case 3 assumes that Griffith's crystal field hypothesis[6] is invalid, and that the solvent shift of the transition is negligible.

The general character of the main chemiluminescence bands for the reaction calls for additional comment. Investigations[14,15] of the absorption spectrum of O_2 in the liquid and solid states, and at high pressures in the gas, show band contours and relative band intensities which differ markedly from those observed and expected for unperturbed gaseous O_2. The Franck–Condon intensities for the transition in the latter case are of the order 10/0·4/0·001 for the 0–0, 0–1 and 0–2 bands, respectively. Like the condensed phase and high pressure spectra, the main chemiluminescence bands also show anomalous 0–1 intensity relative to the 0–0 band, whereas the 0–0 and 0–1 weak bands reported by Browne and Ogryzlo[4] suggest apparently normal intensity ratios, confirming the assignment of these weak bands to gaseous oxygen.

At this stage we do not find it possible to decide unequivocally between case (1) and cases (2) or (3), until we have high resolution investigations of the gas phase $2(^1\Delta_g) \rightarrow 2(^3\Sigma_g^-)$ bands (with assurance of no hydration), understand the rotational structure expected for these superposition transitions, or have direct absorption data for the $^1\Sigma_g^+ \leftarrow {}^3\Sigma_g^-$ transition for O_2 dissolved in water.

The main purpose of these investigations is to gain information on the metastable electronically excited states of molecular oxygen originating from inorganic and organic peroxide breakdown. If, as we believe, the metastable $^1\Sigma_g^+$ or $2(^1\Delta_g)$ states can be generated for oxygen dissolved in water, such a metastable species could play a very important part in reaction mechanisms. In the gaseous state the $^1\Sigma_g^+$ state has a mean lifetime of about 7 sec; in water solution this could be diminished several orders of magnitude, but even such a resulting lifetime would be a long one in terms of reactions in the liquid phase.

We acknowledge the use of a plate obtained by Drs. V. G. Krishna and A. Llewellyn for the electrodeless discharge of gaseous O_2. This work was supported by contracts with the Physics Branch, U.S. Office of Naval Research, and with the Division of Biology and Medicine, U.S. Atomic Energy Commission. A special grant from the Charles F. Kettering Foundation to one of us (M. K.) is acknowledged with thanks.

ORIENTATION OF PYROPHYLLITE SYNTHESIZED IN SLOWLY STRAINED MATERIALS

By Dr. W. D. MEANS
Geology Department, University of Otago
AND
Dr. J. ROGERS
New Zealand Geological Survey, Chemistry Department, University of Otago, Dunedin

A DISTINGUISHING feature of slates is parallel orientation of minute platy grains of mica and other phyllosilicates. The familiar splitting property called slaty cleavage arises from this grain orientation pattern, or fabric. It is generally recognized that the mica in slates grows during metamorphism and that its orientation results from anisotropic stress conditions or consequent flow in rock bodies, but there is no general agreement on the geometric relation between slaty cleavage and directions of stress or flow[1]. Experiments with model materials[2] have shown that random platy particles can be made parallel by deformation of an enclosing plastic matrix.

The following describes exploratory experiments in which the phyllosilicate, pyrophyllite, was synthesized hydrothermally in slowly strained materials. Pyrophyllite fabrics were obtained that are broadly similar to those of micas in slates.

Experiments were run at 425°–475° C and 1,000 atm. water pressure, conditions under which pyrophyllite had been grown by previous workers[3]. Three starting materials were used: a quartz–kaolin claystone and 4 : 1 molecular mixtures of amorphous silica–chi-alumina and amorphous silica–amorphous alumina. The reactions were:

$$\underset{\text{kaolin}}{Al_2Si_2O_5(OH)_4} + 2SiO_2 \rightarrow \underset{\text{pyrophyllite}}{Al_2Si_4O_{10}(OH)_2} + H_2O$$
$$\underset{\text{quartz}}{}$$

$$4SiO_2 + Al_2O_3 + H_2O \rightarrow Al_2Si_4O_{10}(OH)_2$$

The claystone, from the Gore Lignite Measures, Southland, New Zealand (*S*171/220461), contained some illite and had the appearance and consistency of blackboard chalk. X-ray diffractograms, electron micrographs and differential thermal analysis indicated a platy variety of kaolin. The claystone lacked visible stratification in hand specimens but contained kaolin and illite grains with basal planes preferentially parallel to bedding. Cylinders were cored normal and parallel to bedding and fitted in open-ended brass jackets 15 mm long, with internal diameters of 10 mm and external diameters of 12·7 mm.

The oxide mixtures provided homogeneous starting materials with minimum orientation. Chi-alumina is a poorly ordered alumina[4], and that used (Merck chromatographic) gave typical diffuse X-ray reflexions. The amorphous alumina (prepared by heating May and Baker aluminium nitrate to 350° C under reduced pressure) and the silica ('Mallinckrodt' analytical reagent silicic acid, 12 per cent loss on ignition), gave no X-ray reflexions and were optically isotropic. Cylinders of the oxide mixtures were formed by pressing the powder into brass jackets with internal diameters of 10 mm or 12·7 mm, depending on whether the piston was intended to bear on the specimen and jacket together—or on the specimen alone (Fig. 1). The larger type of jacket and specimen were supported by a thick steel cylinder to limit radial expansion.

The specimens were compressed axially at constant strain rates (3–13 per cent/day) by a stainless-steel piston (12·7 mm diam.) in a stainless-steel pressure bomb 36 cm high which was held in a press. The lower 15 cm of the bomb was surrounded by a furnace and the upper third was cooled by an air jet to prevent leakage of water pressure through the piston seal (a graphite–asbestos chevron packing). Water vapour filled the interior of the bomb and had access to the specimens.

Fabrics of the experimental products were assessed by examination of thin sections and by comparison of the X-ray diffractometer peak heights obtained from a surface cut parallel to the cylinder end (1–3 mm from an end) with those from a surface normal to the cylinder end. Exterior surfaces were usually not mineralogically representative of the interior (for example, rich in kaolin, cristobalite). The approximate amounts of pyrophyllite lying parallel and sub-normal to the surface irradiated were indicated by the heights of the basal peaks and of the *hk*0 peak at about 20° 2θ (Cu $K\alpha$ radiation).

After more than 2 days at 450° C and 1,000 atm. water pressure abundant pyrophyllite was found in unstrained claystone cylinders which had not been deformed. Pyrophyllite grew more slowly in unstrained cylinders of amorphous silica and chi-alumina under these conditions. Reaction occurred in three days, but unreacted material remained, especially in the centre of the cylinder, after eleven days. Thin sections and X-rays showed pyrophyllite with basal planes preferentially parallel to bedding in unstrained cylinders of claystone. By contrast the pyrophyllite in an unstrained chi-alumina–silica cylinder showed no detectable preferred orientation in thin section and only weak orientation was suggested by X-rays.

The deformation experiments were of two types determined by the arrangements of piston, etc., shown in Fig. 1: (*a*) shortening accompanied by radial expansion; (*b*) shortening with little or no radial expansion. The chief observations from experiments of type (*a*) were:

(1) Claystone cylinders compressed normal to bedding and shortened less than 50 per cent had pyrophyllite fabrics with no marked differences from those of unstrained cylinders.

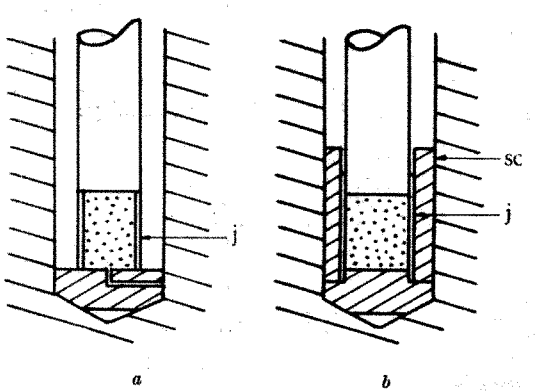

Fig. 1. Arrangement of piston, specimen, and brass jacket (*j*) for (*a*) deformation with radial expansion, (*b*) deformation with radial constraint provided by thick steel cylinder (*sc*)

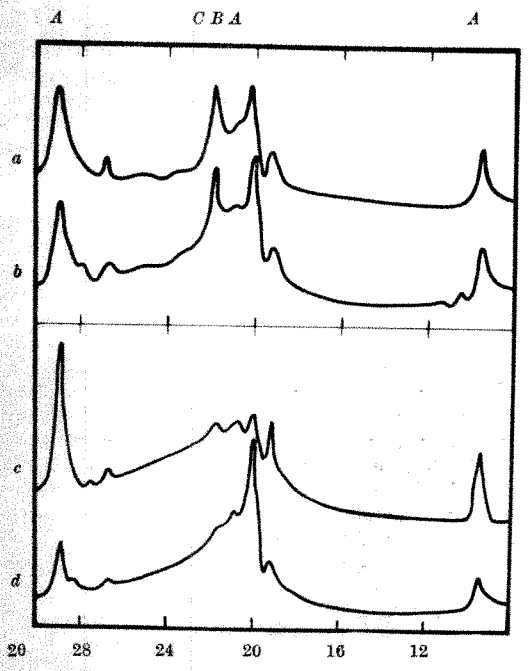

Fig. 2. Diffractometer traces from unstrained and strained chi-alumina–silica cylinders. All surfaces of comparable size. Copper $K\alpha$ radiation. *a*, Surface parallel to and 3 mm from end of cylinder held without strain for 11 days at 1,000 atmospheres water pressure and 450° C. *b*, Surface normal to end of cylinder *a*. *c*, Surface parallel to piston face and 1·5 mm from end of cylinder shortened 42 per cent in eight days at 1,000 atmospheres water pressure and about 475° C. *d*, Surface normal to piston face in cylinder *c*. *A*, 00*l* reflexions from pyrophyllite. *B*, *hk*0 reflexions from pyrophyllite. *C*, 101 reflexions from cristobalite

(2) A claystone cylinder compressed parallel to bedding and shortened 65 per cent in six days at 1,000 atm. water pressure and about 475° C contained pyrophyllite and mica crystals predominantly oriented with basal planes parallel or sub-parallel to the piston face, and thus at a high angle to the initial orientation of bedding. In this experiment the jacketed cylinder expanded radially and met the walls of the bomb at about 60 per cent strain.

(3) A chi-alumina–silica cylinder shortened 75 per cent in eleven days at 1,000 atm. water pressure and about 425° C contained pyrophyllite predominantly with basal planes parallel or sub-parallel to the piston face. This cylinder also expanded to meet the walls of the bomb at about 60 per cent strain. Pyrophyllite grains comprised about 20 per cent of the specimen except at its base, where there was a 0·3 mm oriented layer of pure pyrophyllite.

When radial expansion was restricted in experiments of type (*b*), oriented pyrophyllite was also obtained with oxide specimens as follows.

(4) A chi-alumina–silica cylinder shortened 42 per cent in eight days at 1,000 atm. water pressure and about 475° C contained about 50 per cent of pyrophyllite, again mainly with basal planes parallel or sub-parallel to the piston face. Diffractometer traces from this material are shown in Fig. 2 along with traces from an unstrained cylinder for comparison.

(5) An amorphous alumina–silica cylinder shortened 60 per cent in 4·5 days at about 475° C and water pressures fluctuating between 500 and 1,000 atm. had a pyrophyllite fabric similar to (4). A representative part of this specimen is shown in thin section in Fig. 3.

In all claystone cylinders shortened more than a few per cent some irregular slickensided fracture surfaces were characteristic. These made no regular angle with the cylinder axis and were typically at least a millimetre apart. In the claystone cylinder shortened 65 per cent there were fracture-free blocks up to 2 mm across. The deformed oxide cylinders showed very few fractures in thin section and were more coherent than deformed claystone cylinders. The cylinders deformed 42 per cent and 75 per cent had hardnesses of 3 and 4 on Moh's scale. Claystone specimens changed colour from white to grey with increasing deformation. Oxide specimens remained white.

The optical and X-ray methods of examining products detected marked preferred orientation but did not allow

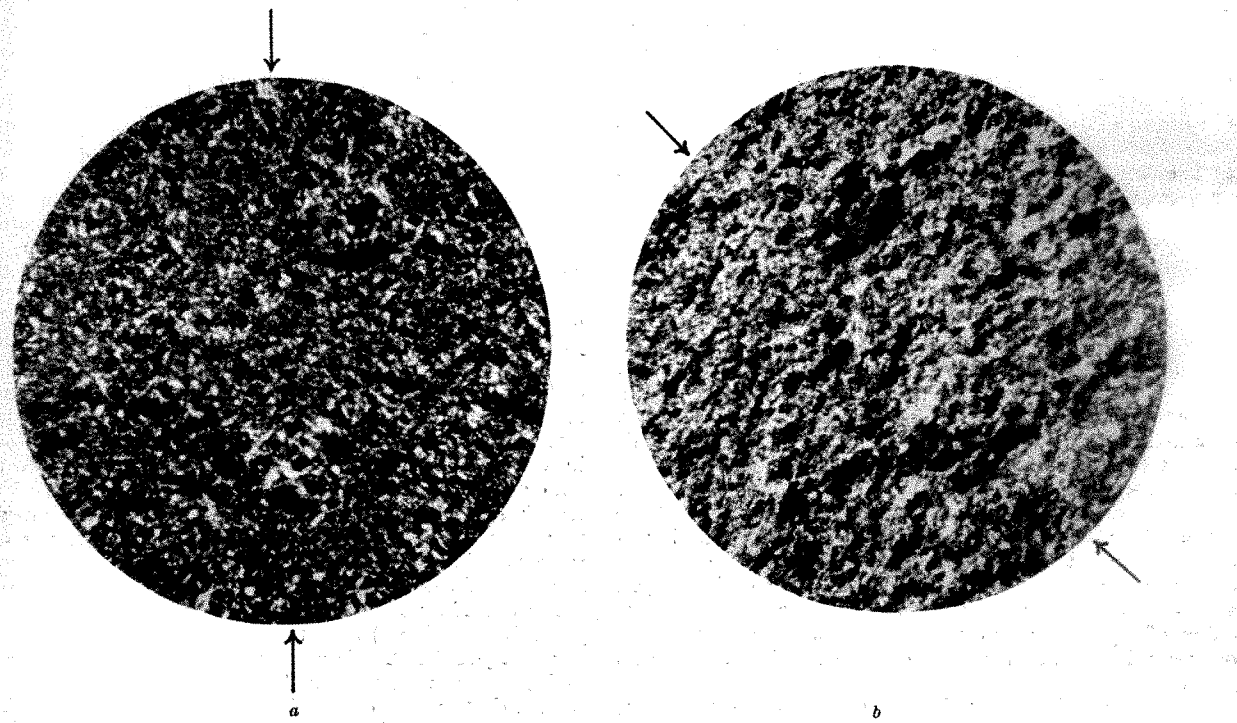

Fig. 3. Thin section normal to piston face from amorphous alumina–silica cylinder shortened 60 per cent. Field diameter 0·5 mm. Crossed nicols. *a*, Trace of piston face E–W; *b*, trace of piston face in 45° position. Most grains illuminated in *b*; but dark in *a* are pyrophyllite oriented with trace of (001) parallel or subparallel to trace of the piston face

detailed description of the fabrics, for example, whether more pyrophyllite lay parallel to the piston face or at 5° or 10° to it. There were indications in thin sections of some deformed oxide cylinders that most of the pyrophyllite lay at some such small angle to the piston face and that it was concentrated in poorly defined symmetrically oriented zones that made a moderate angle (30°–40°) with the piston face.

Strain and grain orientation mechanisms in these experiments are incompletely known. Strain in claystone cylinders was accomplished at least in part by rupture and relative movement of blocks. In oxide cylinders intergranular slip on a fine scale almost certainly occurred. In all experiments there were movements on an ionic or molecular scale during chemical reaction and these probably contributed to total strain. Oriented overgrowth on kaolin and illite grains may have been responsible for mimetic orientation of pyrophyllite in unstrained claystone cylinders. In the deformation experiments orientation may have resulted from rotation of crystals, from nucleation or growth of crystals in certain orientations, or from a combination of these mechanisms.

Pyrophyllite was the main phyllosilicate grown in most experiments with the claystone. Specimens containing muscovite as the only phyllosilicate were prepared by adding potassium carbonate to the bomb. This was not done regularly, however, because the strongest basal X-ray reflexion of muscovite overlaps with the strongest quartz reflexion and because of the difficulty of distinguishing reflexion intensity changes from recrystallization of illite from those marking synthesis of muscovite.

Temperatures, strain rates and growth rates were probably higher in the experiments than in natural slate-producing environments; effective confining pressures may have been lower at least in the experiments involving radial expansion. The experiments demonstrate that an oriented fabric can form while a phyllosilicate is synthesized hydrothermally from material undergoing slow strain.

The experiments were performed in the high pressure-temperature laboratory of the Chemistry Department, University of Otago. The assistance of Mr. V. G. Tyrrell and Mr. E. McKenzie in making the apparatus, and also the preparation of electron micrographs of the claystone by the Physics and Engineering Laboratory, Department of Scientific and Industrial Research, is gratefully acknowledged. The claystone was collected by Mr. D. G. Bishop, and Mr. N. Miller calibrated the strain gauges. We also thank Mr. B. W. Collins, Prof. D. S. Coombs and Dr. M. S. Paterson for their advice.

FACTORS INFLUENCING THE RADIO-PROTECTION OF TISSUE CULTURE CELLS BY SULPHYDRYL COMPOUNDS

By A. J. VERGROESEN, Miss L. BUDKE and Prof. J. A. COHEN

Medical Biological Laboratory, National Defence Research Organization T.N.O., Rijswijk, Z.H., Holland

In previous publications[1–3] results were described indicating that the radio-protective action of cysteamine at the cellular level increases with higher concentrations of this sulphydryl compound. Révész and Bergstrand[4] demonstrated that higher concentrations of cysteamine in the medium resulted in an increased intracellular non-protein sulphydryl content. At equimolar concentrations of the compound this increase appeared to be of a closely similar magnitude as the amount of radio-protection found in our tissue-culture system. These results suggest that radiation protection is dependent on the concentration of the non-protein-bound sulphydryl content effected in the protected cell. Vos *et al.*[2] reported that cysteamine provided a better radio-protective effect than cysteine at equimolar concentrations. Since the dissociation constant of the –SH group of cysteamine (pK $8{\cdot}50 \pm 0{\cdot}14$) is different from that of cysteine (pK $8{\cdot}9 \pm 0{\cdot}2$) at the physiological pH of 7·3, this will result in important differences in the $-S^-$ ion concentration at equimolar concentrations of these compounds. This suggested that not the concentration of –SH groups but that of their dissociated form, namely, the $-S^-$ ions, might be responsible for the protection against radiation. Two types of experiments were performed to test this hypothesis. First the radio-protective effect of equimolar concentrations of sulphydryl compounds of different pK values was determined and secondly the radio-protective effect of equimolar concentrations of a given sulphydryl compound was measured in culture media at different pH values.

The amount of radiation damage caused by X-irradiation (physical constants: 250 kV, 15 m.amp, half-value layer 1·9 mm copper, filtration 1·5 mm copper corrected, dose rate 200 r./min, maximal back-scatter) was assayed by the loss of reproductive integrity of human kidney cells[1–3]. The cells were cultured at 37° C during 13 days, using Puck's feeder layer technique[5], in modified Petri dishes, consisting of glass rings fitted with a 'Melinex' bottom. The culture medium consisted of 0·5 per cent lactalbumin hydrolysate in Hanks's salt solution and 5 per cent calf serum, supplemented with 100 I.U. of penicillin and 0·1 mg of streptomycin/ml. For the experiments it was essential that the pH of the solution remained constant during the whole prophylactic incubation period before and during irradiation. Therefore another culture medium[6], wherein Hanks's solution was replaced by a phosphate buffered salt solution, was used to dissolve the sulphydryl compounds. The pH of this culture medium was 7·3 and could be varied between pH 6·3 and pH 8·3. This medium was also used before and during the irradiation of non-treated cells and of the cells made anoxic by flushing with oxygen-free nitrogen[1,3]. All solutions were freshly prepared, added to the cells 10 min before irradiation and removed directly afterwards by washing three times with the standard culture medium. The dose-reduction factors (DRF) were calculated by drawing the best fitting curve through the experimental points and dividing the X-ray dose giving 10 per cent survival of the treated cells by the dose giving the same survival of the non-treated cells.

First, different sulphydryl compounds with diverging pK values (Table 1) were tested in equimolar concentrations at pH 7·3. Their radio-protective effects expressed in DRFs are presented in Table 2. Since it is not excluded that anoxia caused by autoxidation of the sulphydryl compounds is partly responsible for the radio-protective action, the experiments were repeated under anoxic conditions. Anoxia was established by flushing

Table 1. *p*K VALUES AND PERCENTAGES OF DISSOCIATED –SH GROUPS OF THE TESTED SULPHYDRYL COMPOUNDS AT *p*H 7·3

Sulphydryl compound	*p*K	Percentage –S⁻ at *p*H 7·3
Cysteamine	8·50 ± 0·14	4–8
d- and *l*-Cysteine	8·9 ± 0·20	1–2·5
l-Glutathione	9·28 ± 0·07	1·0
Thioglycol	9·60 ± 0·03	0·5

Table 2. DOSE REDUCTION FACTORS (DRF) OBTAINED WITH DIFFERENT CONCENTRATIONS OF SULPHYDRYL COMPOUNDS (Incubation before irradiation: 10 min at room temp.)

Sulphydryl compound	DRF at *p*H 7·3

Thioglycol	2·5	2·9	3·3	3·6

Table 4. DRF OBTAINED WITH CONSTANT CONCENTRATIONS OF A SULPHYDRYL COMPOUND AT DIFFERENT *p*H VALUES (Incubation: see Table 2)

Sulphydryl compound	Concentration (mM)	DRF at *p*H		
		6·3	7·3	8·3
Cysteamine	16	2·3	3·5	4·8
l-Cysteine	32	3·0	—	4·4
Thioglycol	100	2·8	2·9	3·8
Thioglycol	200	—	4·0	4·7

Table 5. DRF OBTAINED WITH CONSTANT CONCENTRATIONS OF CYSTEAMINE UNDER ANOXIC CONDITIONS AND AT DIFFERENT *p*H VALUES (Incubation: see Table 2)

Pretreatment (10 min)	DRF at *p*H		
	6·3	7·3	8·3
Nitrogen	2·4	2·5	2·5
Nitrogen + 8 mM cysteamine	3·7	4·1	4·7
Nitrogen + 16 mM cysteamine	4·1	4·5	4·9

with oxygen-free nitrogen during the incubation with a sulphydryl compound in a modified closed culture vessel[3]. After 10 min of this treatment less than 15 p.p.m. of oxygen could be demonstrated with a Hersch cell[7] connected with the outlet of the culture vessel. The DRF values obtained after this combined pretreatment at *p*H 7·3 are presented in Table 3. It will be seen that with the exception of thioglycol the radio-protective potency of the sulphydryl compounds increases with decreasing *p*K value. The differences in effect between *d*- and *l*-cysteine in equimolar concentrations are relatively small but might indicate that the steric configuration near the –S⁻ group is of some importance for the mechanism of radio-protection. Thioglycol gave a better radio-protection than could be expected from its low –S⁻ concentration at *p*H 7·3. Dewey[8] postulated on account of his experiments with *Serratia marcescens* that at higher concentrations the –OH group of thioglycol is responsible for a radio-protective effect in addition to the effect of the –SH group. High concentrations of various alcohols also provided in our tissue-culture system a considerable radio-protective effect (Vos, to be published). For this reason it seems reasonable to explain the deviating protection of thioglycol on account of its –OH group.

Next we tested our hypothesis by changing the *p*H of the solution and keeping the concentration of the sulphydryl compound constant. It could be shown that the cells could withstand a 30-min exposure to culture media at a *p*H varying between 6·3 and 8·3 without loss of plating efficiency. The results of pretreatment with cysteamine, *l*-cysteine and thioglycol at different *p*H values are presented in Table 4. Variation of the *p*H of the medium did not influence the radiosensitivity of the otherwise untreated cells. These experiments were repeated under anoxic conditions to exclude the possible influence of variation in the degree of hypoxia at the different *p*H values. The results are presented in Table 5. From both groups of experiments it follows that the radio-protective effect of equimolar concentrations of a given sulphydryl compound increases with increasing *p*H.

The results presented here indicate a correlation between the radio-protective action of the sulphydryl compounds and the extent of their dissociation in the medium. The concentration of the –S⁻ ion thus depends on the *p*K value of the sulphydryl compound, the concentration of the compound and the *p*H of the medium. Kohn and Gunter[9] earlier reported that the radio-protection of *E. coli B* and *B/r* by *l*-cysteine was less at *p*H 5·3 than at *p*H 7·8 ; this result was confirmed by Dewey[10] in similar experiments with *Serratia marcescens*. More experimental evidence will be required to prove our hypothesis. At present our work is extended to include more thiol compounds and their penetration into the cells. The present hypothesis might be of value in the search for more powerful radiation protectors.

We thank Dr. O. Vos for his advice and Dr. A. W. Kaandorp, Chemical Laboratory of this Organization, for determining *p*K values.

DEVELOPMENT OF RIBONUCLEIC ACID POLYMERASE IN CELLS INFECTED WITH ENCEPHALOMYOCARDITIS VIRUS AND THE SYNTHESIS OF SINGLE- AND DOUBLE-STRANDED RNA BY THE ISOLATED POLYMERASE

By DR. E. HORTON, DR. S.-L. LIU, DR. L. DALGARNO, DR. E. M. MARTIN and DR. T. S. WORK

National Institute for Medical Research, Mill Hill, London, N.W.7

THE replication of viral RNA in cells infected with the small RNA-containing viruses is thought to be catalysed by an RNA-dependent RNA polymerase the synthesis of which is induced by the invading viral genome. Franklin *et al.* have described the presence of such an enzyme in HeLa cells infected with poliovirus[1] and in *L* cells infected with mengovirus[2]. In both instances, the polymerase catalyses the incorporation of

nucleoside triphosphates into RNA in the presence of actinomycin *D*, in contrast to the normal cellular DNA-dependent RNA polymerase. The enzyme could not be detected in uninfected cells, and its activity increased concurrently with the increase in intracellular titre of virus.

The RNA polymerases of Krebs II ascites tumour cells infected with murine encephalomyocarditis (EMC) virus have been examined by Cline, Eason and Smellie[3]. They found a polymerase which differed markedly from that described by Franklin's group. This enzyme was present in uninfected cells and its activity increased during infection in a manner unrelated to the growth of the virus. It was present in both nuclear and cytoplasmic extracts and was sensitive to ribonuclease. The enzyme reaction product was not characterized other than by demonstrating its lability to alkali.

The methods for extraction and assay of polymerase used by Cline *et al.* differed from those used by Franklin *et al.*, and the possibility therefore arises that more than one polymerase may be induced during infection. As part of an examination designed to locate the site of synthesis of viral RNA in Krebs cells infected with EMC virus, we have re-examined the situation as far as the virus-specific RNA polymerase is concerned. We have found that two types of polymerase are present in the infected cell. One of the enzymes is similar to that found in polio- and mengo-infected cells and it is probably concerned in catalysing the synthesis of progeny viral RNA.

Preparation of RNA polymerase from infected cells. Krebs II ascites tumour cells were prepared as a suspension ($1{\cdot}5 \times 10^7$ cells/ml.) in Earle's medium containing 3 μg/ml. of actinomycin *D*. EMC virus (3–5 plaque forming units/cell) was added and the suspensions left overnight at 4°. Virus growth was initiated by raising the temperature to 37°. Details of the incubation of cells and assay of virus are given in ref. 4. Samples of about 10^9 infected or control cells were removed 5·5 h after initiation of infection, washed with buffered saline, then with 0·25 M sucrose–1 mM $MgCl_2$ and then suspended in 20 times their packed cell volume of water. The cells were disrupted with a Dounce homogenizer[5] and *tris*-hydrochloric acid buffer, *p*H 8·3, and $MgCl_2$ were added to a final concentration of 0·1 M and 5 mM respectively. Sodium chloride was added to a final concentration of 0·5 M and, 10 min later, the homogenate was diluted with an equal volume of water. The suspension was centrifuged at 600*g* for 10 min, and the supernatant centrifuged for a further 60 min at 100,000*g*. The pellet from this spin was suspended in 0·25 M sucrose–1 mM $MgCl_2$ and assayed for its ability to catalyse the incorporation of ^{14}C–ATP into acid precipitable products in the presence of actinomycin. The assay method was based on that described by Baltimore and Franklin[2]. The results are summarized in Table 1.

Table 1. RNA Polymerase Activities of Infected Cell Homogenates

	Incubation mixture	AMP incorporated (μμmoles/mg protein)
Complete	none	135
,,	uninfected cells	10
,,	omit CTP, GTP, UTP	103
,,	omit $MgCl_2$	45
,,	omit phosphoenol pyruvate	33
,,	add ribonuclease	97
,,	add deoxyribonuclease	150

Homogenates from cells infected with EMC virus for 5·5 h were prepared as described in text. The assay mixture contained *tris*-HCl *p*H 8·3, 35 μmoles; triphosphates of cytidine, guanosine and uridine, 90 mμmoles each; ^{14}C–ATP (spec. act. 1·55 c./mole), 90 mμmoles; phosphoenol pyruvate, 5 μmoles; pyruvate kinase (C. F. Boehringer and Soehne), 10 μg; $MgCl_2$, 5 μmoles; actinomycin *D*, 1 μg and 0·1 ml. of enzyme preparation containing about 1 mg protein. The final volume was 0·4 ml. 50 μg ribonuclease (C. F. Boehringer and Soehne) and 10 μg deoxyribonuclease (Sigma Chemical Co.) were added where indicated. Incubation was for 15 min at 37°. All activities were corrected for radioactivity in a control incubated at 0°.

Preparations from cells infected for 5·5 h with EMC virus showed appreciable incorporation of ^{14}C–ATP and therefore contained an actinomycin-resistant polymerase. Incorporation, which was negligible in preparations from uninfected cells, required Mg^{++} and an ATP-generating system. The reaction was only partly dependent on the presence of all four nucleoside triphosphates. Deoxyribonuclease did not reduce the incorporation, and it was only partially inhibited by the addition of 50 μg of ribonuclease. The properties of this enzyme preparation from EMC virus-infected cells, therefore, are very similar to those described by Baltimore and Franklin[2] and by Baltimore[6] for their mengovirus-infected L-cells and poliovirus-infected HeLa cells.

Localization of polymerase activity. The sedimentation behaviour of the polymerase from EMC-infected cells was investigated by differential centrifugation. Krebs cells were infected with EMC virus for 5·5 h, washed and disrupted as before. The homogenate was treated at 0° for 10 min with 0·5 M NaCl and diluted with an equal volume of water. This suspension was then fractionated into 'nuclear', large particle and small particle fractions by centrifugation at 600*g* for 10 min, 40,000*g* for 15 min and 100,000*g* for 60 min, respectively. Each fraction was suspended in a small volume of sucrose–$MgCl_2$ solution and assayed for its ability to incorporate ^{14}C–ATP into acid-insoluble products in the presence of actinomycin.

Table 2. Distribution of RNA Polymerase Activities among Subcellular Fractions of Infected Cells

Fraction (*g*-min)	Virus growth when collected (% of final)	Incubation mixture	AMP incorporated (μμmoles/mg protein)
Nuclei (6×10^5)	80	Complete	35
	80	omit CTP, GTP, UTP	20
Large particle (6×10^5)	50	Complete	690
	50	omit CTP, GTP, UTP	300
	50	Complete plus ribonuclease	363
Small particle (6×10^6)	40	Complete	151
	40	omit CTP GTP, UTP	350
	40	Complete plus ribonuclease	26

Assay conditions as for Table 1

The results (Table 2) showed that most of the activity was localized in the large-particle fraction and here all four triphosphates were required for maximum activity. It was unaffected by the addition of mercaptoethanol. Added EMC viral RNA caused only a 20 per cent stimulation of synthesis. The optimum *p*H for polymerase activity in the large particle fraction was 8·0–8·4. In all these respects the enzyme preparation resembles that found by Baltimore and Franklin[2] in polio- and mengo-infected tissue cultures. The large particle fraction does, however, contain some enzyme activity which could be assayed by the addition of ATP alone. This latter 'homo-polymerase' activity was more concentrated in the small-particle fraction and the presence of all four triphosphates inhibited ATP incorporation by the second enzyme. The homo-polymerase activity of the small-particle fraction explains the apparent lack of a specific requirement for all four triphosphates in the assay of the total particle fraction (Table 1). The nuclei contained negligible amounts of actinomycin-insensitive polymerase activity.

Time course of appearance of polymerase activity. Cell suspensions incubated with 5 μg/ml. of actinomycin were taken at various intervals after the initiation of infection with EMC virus. The large-particle fraction was isolated and assayed for actinomycin-insensitive RNA polymerase activity. Samples were also taken for assay of intracellular virus by the hæmagglutinin assay[4]. The results are summarized in Fig. 1. It can be seen that the polymerase activity, which is negligible during the first 3 h, rises to a maximum at about 5 h after infection, and thereafter falls off. The rise in enzyme activity parallels

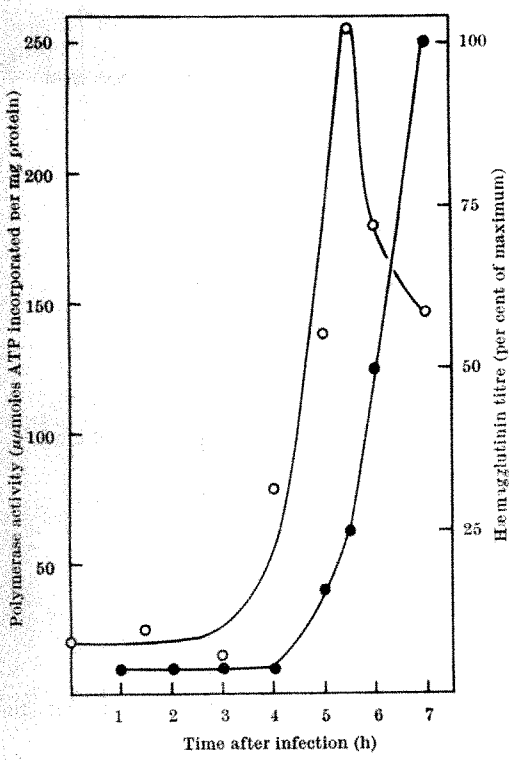

Fig. 1. Time-course of appearance of RNA polymerase activity during infection. ○, RNA polymerase of the large particle fraction from cell homogenates; ●, titre of intracellular virus

the rise in virus titre, but takes place about 1·5 h beforehand. As we have shown previously that the synthesis of the RNA of the mature progeny virus takes place about 1·5 h before the appearance of an equivalent amount of whole virus[7], it is probable that the formation of the enzyme assayed in these experiments was coincident in time with, and responsible for, the appearance of progeny viral RNA.

Nature of the product. The product formed on incubation of the large-particle fraction from infected cells with ^{14}C–ATP was hydrolysed with 0·3 N KOH at 35° for 18 h. It was found that 87 per cent of the radioactivity was rendered soluble in 0·5 N perchloric acid. In one experiment, uridine triphosphate labelled in the α-position with phosphorus-32 was included in the reaction mixture and the product was hydrolysed with alkali and the nucleoside monophosphates separated by electrophoresis[8]. The distribution of radioactivity between the monophosphates of cytidine, adenosine, guanosine and uridine was 27·3, 24·6, 16·7 and 31·4 per cent, respectively. It is evident from these results that the RNA synthesized by the large-particle enzyme was a heteropolymer containing all four nucleotides in normal proportions.

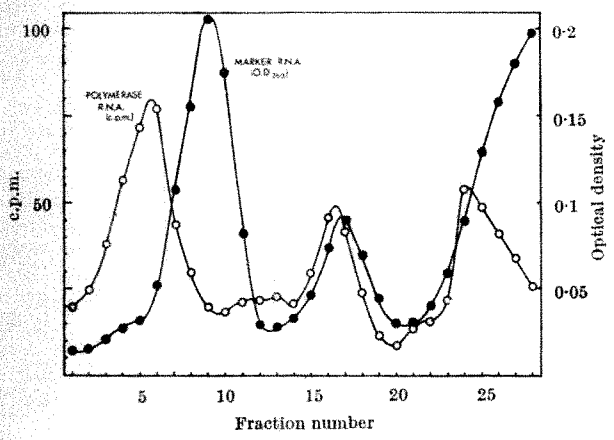

Fig. 2. Sedimentation of the enzyme reaction product on a sucrose gradient. The incubation mixture (0·45 ml.) was thawed with bentonite (2·5 mg) and Krebs cell ribosomes (1 mg) added. Five per cent sodium dodecyl sulphate in 0·05 M potassium phosphate buffer, *p*H 7·4 (3 ml.), was then added and the mixture stirred for 3 min at 37°. It was cooled and 3 ml. layered directly on to a 5–20 per cent sucrose gradient containing 0·1 M NaCl, 10 mM *tris*-HCl *p*H 7·0 and 1 mM EDTA and centrifuged at 0° for 16 h at 24,000 r.p.m. ○, Radioactivity of RNA synthesized by polymerase; ●, optical density of marker RNA

To characterize the product further, its sedimentation behaviour on a sucrose gradient was investigated. After incubating the large-particle fraction with ^{14}C–ATP, the reaction product was mixed with Krebs cells ribosomes, treated with 5 per cent sodium dodecyl sulphate and centrifuged through a sucrose gradient. The gradient was sampled in the usual way and examined for distribution of acid-insoluble radioactivity and optical density at 260 mμ. As shown in Fig. 2 the radioactivity sedimented in three distinct peaks: (1) a fast peak sedimenting well ahead of the 30 *S* ribosomal RNA marker; (2) an intermediate peak of about 20 *S*; (3) a slowly sedimenting peak of 4–6 *S*. When the reaction product was run on a sucrose gradient together with RNA extracted from purified EMC virus, the fastest peak corresponded with the viral RNA marker ($S_{20,w}$ = 37 *S* (ref. 9)). The molecular weight of one of the products of the enzyme reaction is therefore similar to that of the RNA of the mature virus particle.

Montagnier and Sanders[10] have reported the isolation from EMC-infected Krebs cells of a double-stranded RNA (20 *S*) which is resistant to digestion with pancreatic ribonuclease. The product obtained from the incubation of the large particle fraction with ^{14}C–ATP was therefore treated with 1 μg/ml. of ribonuclease at 20° for 30 min before detergent treatment and centrifugation on a sucrose gradient. The 37 *S* peak of radioactivity was abolished, but the intermediate 20 *S* peak remained. Hence, this latter material may be identical with the double-stranded RNA reported by Montagnier and Sanders.

When analysed by the sucrose gradient technique the product obtained by incubation of the small-particle enzyme, either with ATP alone or with all four triphosphates, showed only a single major component, which, when compared directly, sedimented in a similar manner to the 4–6 *S* component obtained with the large-particle enzyme and with *E. coli* transfer RNA, the latter used as an optical density marker. The small-particle enzyme appears therefore to catalyse an actinomycin-insensitive incorporation of ATP into transfer RNA, probably into its terminal position, and is similar to that described by Franklin[11].

From the results presented here we deduce that the infecting RNA of EMC virus directs the synthesis of RNA polymerase which catalyses the incorporation of nucleoside triphosphates into two types of RNA—a single-stranded molecule, probably the RNA of the mature virus, and a ribonuclease-resistant form which is most likely double stranded. The relationship of these enzyme products to each other and their involvement in the replicative process is at present being investigated.

Cline *et al.*[4] described an actinomycin-insensitive RNA-dependent polymerase from EMC-infected Krebs cells which was stimulated by the addition of yeast RNA, and was not localized in any particular cell fraction. It was present in uninfected cells. The properties of this polymerase differ greatly from those of the large-particle enzyme described here. It is possible that Cline *et al.* have assayed an enzyme of the type we have observed in the small-particle fraction. This enzyme may not be directly concerned with the synthesis of viral RNA.

Baltimore[3] has reported the formation of reaction products similar to ours when an enzyme from polio-infected HeLa cells was incubated with ^{32}P-labelled GTP. This polymerase was mainly localized in a cytoplasmic fraction sedimenting at 600,000*g*-min. The polymerase of mengo-

infected *L* cells was only partially sensitive to ribonuclease and showed a marked dependence on the presence of all four nucleoside triphosphates and Mg^{++} (ref. 2). In all these respects, and in optimum *p*H and time course of appearance during infection, the polymerase found in EMC-infected Krebs II ascites cells is remarkably similar to the polymerase of mengo- and polio-infected cells.

We thank Dr. R. M. S. Smellie for a gift of ^{32}P–UTP, and Mr. H. D. Brown of Merck, Sharp and Dohme, New Jersey, for a gift of actinomycin *D*. This work was carried out during the tenure of a Damon Runyon Foundation fellowship by E. H. and of a Melbourne University travelling scholarship by L. D.

APPLICATIONS OF ISO-IMMUNE CYTOLYSIS USING RADIOLABELLED TARGET CELLS

By Dr. ARNOLD R. SANDERSON

McIndoe Memorial Research Unit, Blond Laboratories, Queen Victoria Hospital, East Grinstead, Sussex

MANY investigations of iso-immunity have benefited from the use of inbred (isohistogenic) strains of animals, and, of the few species available, the mouse is the most common choice, because of the large background of genetic information available, together with rapidity of breeding and relatively easy economic maintenance of a defined colony. Assays of humoral iso-immunity in mice, which are usually based on agglutination or damage of cellular targets, have a number of drawbacks. Erythrocytes may not possess all the antigens characteristic of their strain of origin[1], while dissociated nucleated white cells may be difficult to prepare in a homogeneous form. Furthermore, the estimation of a humoral effect may be imprecise, as in agglutination, or unduly prolonged, as in cytotoxic tests judged by counting of stained cells. Nevertheless, a great deal of semi-quantitative information about strain specific antigens has been gained by the use of hæmagglutination[2], hæmolysis[3,4], and cytotoxicity[5]; recent modifications[6,7] have been aimed at the development of more objective and quantitative assays.

For stricter quantitation and more definitive analysis of humoral iso-antibodies and iso-antigens in cytotoxic studies, the principal requirements are an easily obtained homogeneous suspension of cells which have a complete spectrum of strain-specific antigens and which release quantifiable substances on lysis. These requirements have been closely approached by the use of mouse lymphocytes which are labelled with chromium-51, and the release of radioisotope effected by specific antisera and guinea-pig complement (*C′*) is used to determine the extent of lysis. Chromium-51 is frequently used in hæmolysis studies, where Weinrach, Lai and Talmage[8] first pointed out that the smaller quantity of cells required enabled a higher *C′*: cell ratio and allowed more precise kinetic determinations. Goodman[9] first suggested the use of chromium-51 as a label for other kinds of cells and used a rabbit anti-Ehrlich (mouse) tumour heteroimmune system, while Wigzell[10] found that the mouse (*C57BL*) tumour, *EL*4, similarly labelled, served as a satisfactory target cell in iso-immune studies. *In vivo* labelled (^{3}H-thymidine; ^{14}C-amino-acids) mouse tumour cells have also been used[11,12] in iso-immune systems.

In the work recorded here normal mouse lymphocytes were used in preference to tumour cells in order to avoid possible complications due to antigenic disparity between a tumour and its specific host, be these differences qualitative or quantitative[4]. The amenability of the assay to precise microanalysis has been studied and several applications are recorded.

The cytolytic assay. The test system used is as follows: lymph nodes from a normal mouse are gently teased apart in Medium 199 (ref. 13) containing 0·1 per cent bovine plasma albumin (Armour Co. Ltd., Eastbourne, Sussex), which is used throughout as diluent. (Manipulation of the small quantities of material involved is achieved by the use of Lang-Levy constriction micropipettes[14] manufactured in the laboratory[15].) A coarse sinter (porosity 0) is used to remove gross debris and clumps of cells, while allowing the passage of dispersed lymphocytes, which are collected by centrifugation and resuspended in a small volume of medium. An equal volume of $Na_2{}^{51}CrO_4$ solution (Radiochemical Centre, Amersham, supplied as 1 mc. samples in isotonic saline, *p*H 7), containing 50–100 μc./μg, is added and the cells are labelled by incubation for 2 h at 37° C. Excess label is removed by washing several times with medium and the cells are finally suspended at $5–6 \times 10^6$/ml.; dead cells rarely exceed 4 per cent. Dilutions (to 0·2 ml. final volume in small tubes, 100 mm × 75 mm) of antiserum are made in medium which contains *C′*. Appropriate controls containing heat-inactivated *C′* and normal mouse serum are always included. The concentration of *C′* used is the maximum amount which will cause less than 5 per cent lysis per h of labelled lymphocytes in the presence of normal mouse serum. An aliquot of labelled, washed, lymphocytes is added to each tube, which is then sealed with a rubber stopper and rolled in an inclined rack, to ensure adequate mixing, at room temperature. After an appropriate time, depending on the purpose of the experiment, reaction is terminated by addition of 0·3 ml. ice-cold versene in isotonic saline at *p*H 7·5 to each tube over the same staggered intervals as was used to add the cells. The tube contents are mixed, centrifuged, and a convenient portion of supernatant solution is removed for estimation of the radioisotope released. The total radioactivity present in an aliquot of lymphocytes is also measured.

Parameters affecting the assay. Using the quantities of radioisotope mentioned above, between 15 and 40 per cent of the available label is incorporated, dependent on the time, temperature and cell concentration during incubation. Bunting, Kiely and Owen[16] have shown that up to 50 per cent of available chromium-51 is incorporated into rat lymphocytes under similar conditions and on osmotic lysis is released in some bound

form not re-incorporated on incubation with further unlabelled cells. Microscopic examination of lymphocytes before and after labelling did not reveal any difference in form or motility, although the dead cell (trypan blue) count decreased, presumably due to fragmentation and solubilization during incubation at 37° C. The 50 per cent titre of an antiserum measured using cells which had been labelled for 2 h was indistinguishable from that obtained using cells labelled for 4 h, showing that labelling of cells did not increase their fragility. Furthermore, it has been reported[17] that tumour cells labelled with chromium-51 under very similar conditions to the above show no evidence of impaired viability. These considerations suggest that for the duration of labelling and subsequent lysis the presence of radioisotope does not alter the lytic characteristics of the lymphocytes, a conclusion which is supported by an accumulation of evidence from erythrocyte labelling[18,19].

Careful attention to reaction time and temperature was necessary to ensure reproducibility. The guinea-pig complement used was from a pool of animals: it required absorption with mouse cells (spleen) before use in order to reduce blanks, and proved stable for several weeks when stored sealed and frozen at −20° C. Not all the incorporated radioisotope is released from cells on complete lysis, although all cells are dead as judged by trypan blue staining: a maximum of 60–70 per cent of the label incorporated is usually released. For reasons to be discussed later it is believed that the measurable extent of label release is dependent on the degree of damage suffered by the strain of lymphocytes in question together with the amount of insoluble bound isotope removed by centrifugation, and is not necessarily a reflexion of heterogeneity in the cell population with respect to fragility or antigenic content.

After subtraction of control values, which for acceptance should be less than 5 per cent of the maximum release, the degree of lysis caused by antiserum may be calculated. Maximum isotope release is taken to be 100 per cent lysis and is usually arranged to occur in several tubes at the higher concentrations of antiserum. Occasional prozones are seen which are presumably due to an anti-complementary effect of mouse serum or the presence of some other inhibitor[20] of immune lysis effective at high mouse serum concentrations.

When the foregoing factors are taken into consideration, the assay as described yields results which are as precise as those obtained in the classical rabbit antisheep hæmolysis[21]. When analysed by the method of von Krogh[22], which uses an empirical expression to relate lysis to antiserum dilution, results such as those shown in Fig. 1 were obtained.

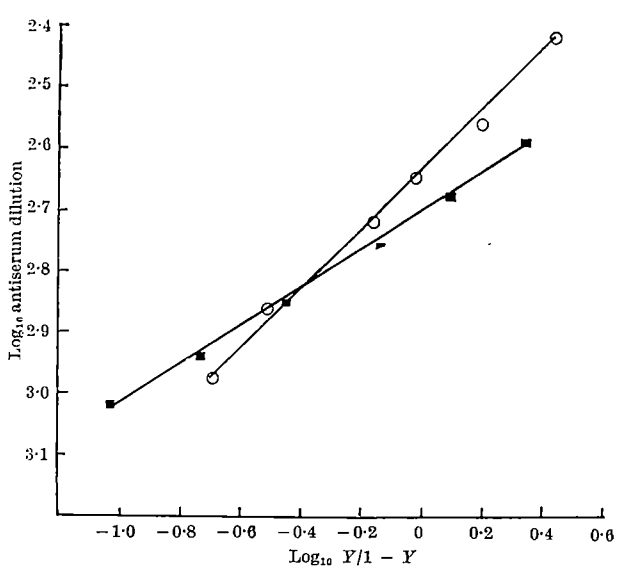

Fig. 1. Von Krogh analysis of cytolysis. Y is the fraction of cells lysed. ○, Lysis of *C3H* lymphocytes with *DBA*/2 anti-*C3H* serum; ■, lysis of *DBA*/2 lymphocytes with *C3H* anti-*DBA*/2 serum

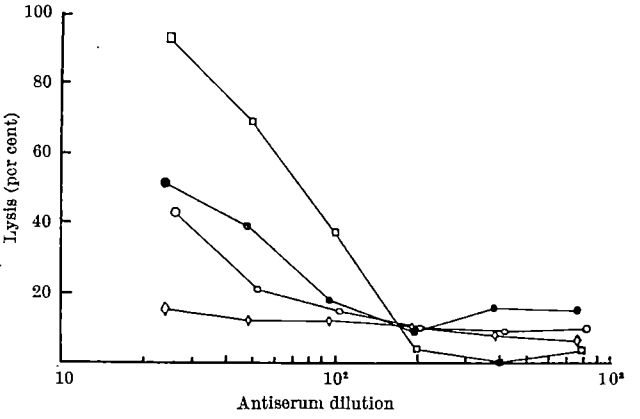

Fig. 3. Titration of antisera with *DBA/2* lymphocytes: demonstration of non-*H*-2 interaction. □, *CBA* anti-*DBA/2*; ●, *BALB/c* anti-*C3H*; ○, *BALB/c* anti-*CBA*; ◇, *BALB/c* anti-*DBA/2*

Antiserum	Potential *H*-2 specificities in antiserum	Potential *H*-2 specificities expected to react with *DBA/2* target
CBA anti-*DBA/2*	*DE^{d}FMJNRA'B'C'*	*DE^{d}FMJNRA'B'C*
BALB/c anti-*C3H*	*AEKY*	None
BALB/c anti-*CBA*	*AEKY*	None
BALB/c anti-*DBA/2*	None	None

Similar data from other combinations of iso-immune sera have established that the slope of a von Krogh analysis of C' titration is very close to 0·2, while kinetic studies under conditions of limited C' or limited antibody behaved as in the rabbit antisheep system[21]. When analysed by the method of Weinrach *et al.*[8] many sera showed an order of reaction close to 2 with respect to antiserum. The lag period in 'complement first' studies was 17–19 min, similar to that found by these authors[23], while kinetic examination of the lysis of pre-sensitized ('antiserum first') lymphocytes showed no such lag, and proceeded at a steeper initial lytic rate. The similarity of the iso-immune systems mentioned here and the rabbit antisheep hæmolysis which has been so carefully studied make it seem likely that the molecular events causing lysis in the two cases are the same. The mouse situation possesses one advantage, that of a defined antigenic and uniform genetic background, and further studies could prove fruitful. In the foregoing work, the meaning of C' units and antiserum units, as well as target cell concentrations and lytic conditions, have been operationally defined for relevance to the mouse system, and are considerably different from those used in sheep erythrocyte immune lysis[21].

Applications of the assay. The pattern of iso-antigenic specificities in mice which are controlled by the *H*-2 genetic locus has been elaborated[24] using skin grafting, tumour grafting and hæmagglutination. The applicability of the present assay to the same problem was tested as shown below. Each of 6 strains of mice (*A/Jax*; *C57BL*; *C3H/He*; *CBA*; *BALB/c*; *DBA/2*) was separately immunized against each of the other five, by weekly (five) injections of spleen suspensions. The 30 antisera produced were separately tested for cytolytic activity in the presence of *C′*, against panels of labelled lymphocytes derived from each strain of mouse. The 180 results thereby included specificity controls, since each antiserum was tested against lymphocytes of the strain from which it was produced: no abnormal results were recorded in such controls. The pattern of titres so obtained not only included every reaction predicted from the known distribution of *H*-2 specificities but also contained several unpredicted results; this is presumably a reflexion of the more complete or more dense representation of *H*-2, and possibly non-*H*-2, specificities on lymphocytes than on erythrocytes. Titres were found to be reproducible within a few per cent when performed by different investigators on different days using different samples of the same batch of antiserum, and *C′*. Examples of such titres are presented in Fig. 2. 100 per cent lysis in this figure represents 65 per cent release of radioisotope.

Antigenic heterogeneity in the target cell population is unlikely to be the reason for incomplete release, because of the identical maximum liberation caused by several antisera of known widely different specificities, a result which has been noted many times in the combinations of sera and targets used, most strikingly in the parent/hybrid case mentioned later.

Table 1. 50 PER CENT TITRES FOR ANTISERA DIRECTED AGAINST PARENT AND HYBRID CELLS: THE 'GENE-DOSE' EFFECT

Antisera	Target lymphocytes *C3H*	*BALB/c*	(*C3H* × *BALB/c*) *F*1 hybrid
C3H anti-*BALB/c*	—	222	117
BALB/c anti-*C3H*	256	—	135
C3H anti-*BALB/c* + *BALB/c* anti-*C3H*	270	231	232

It is worth noting that although no examples of interaction were noted between targets and antisera when the latter were produced between mice differing only at non-*H*-2 loci, nevertheless non-*H*-2 interaction could be demonstrated as shown in Fig. 3. This confirms the findings of others[25] that the normally weak response to non-*H*-2 differences between mice may be considerably augmented when it is accompanied by an *H*-2 incompatibility: Fig. 3 represents the serological demonstration of this effect.

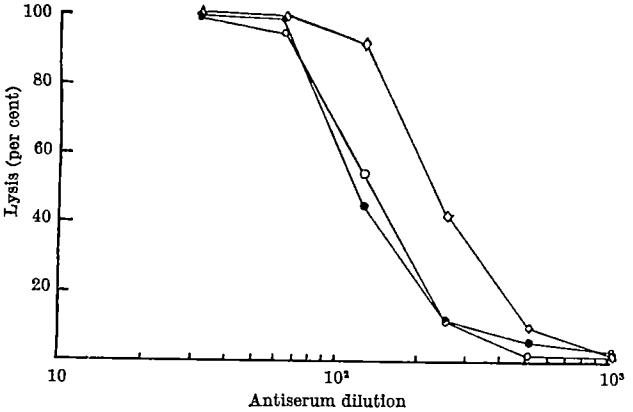

Fig. 4. Titrations of antisera with (*C3H* × *BALB/c*) *F*1 hybrid lymphocytes: demonstration of the additive effects of different specificities against the same target cell. ●, *C3H* anti-*BALB/c*; ○, *BALB/c* anti-*C3H*; ◇, *C3H* anti-*BALB/c*, *BALB/c* anti-*C3H*

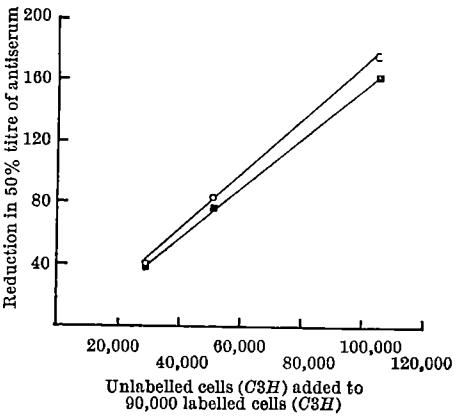

Fig. 5. Relationship of antigen added, in the form of lymphocytes (*C3H*), to the reduction in 50 per cent titre of *DBA/2* anti-*C3H*. ○, Calculated from von Krogh analysis of lysis; ■, calculated from Weinrach *et al.* analysis of lysis

An interesting application of the cytolytic technique throws quantitative light on two problems which have recently received attention, namely: (*a*) the additive cytotoxic effect of antisera directed against different antigenic specificities of the same target cell[4,26]; (*b*) the so-called 'gene-dose'[4,7,27,28] effect. The latter refers to the change in the phenotypic expression of a genetically controlled characteristic when the amount of genetic material is altered. This can conveniently be examined using mouse histocompatibility specificities as indicators. The homozygous genes controlling mouse *H*-2 antigenic specificities are believed to be co-dominant, that is, the heterozygous *F*1 hybrid will qualitatively exhibit all the specificities present in its parents. That this relationship is quantitative is shown in Table 1, and Fig. 4 shows the additive effect of different specificities in antisera directed against the same target.

The sensitivity of a hybrid lymphocyte to an antiserum directed from either parent against the other is almost exactly half that of either appropriate parental cell. Furthermore, the sensitivity of the hybrid cell to a combination of the antisera is the same as the respective parental cells to their appropriate antisera, showing that the inherited antigenic specificities which dominate the lysis of the cells concerned are present at half the density on the hybrid cell at which they occur on the respective parental genetic donor. It is, of course, fortuitous (and fortunate for the demonstration of this experiment) that the titres of the antisera against the hybrid target shown in Fig. 4 are so close, but, had they not been, appropriate dilution with normal mouse serum would have enabled the same effect to be revealed. Möller[26] was able to show a qualitative additive effect by combining antisera raised between different strains of mice which would be expected to react against antigens present in the chosen tumour cell targets, but it would be difficult in his experimental design to separate the effects of addition of different antibody specificities from the cumulative effects of the same antibody specificities in different antisera. The use of parental and hybrid targets precludes this possibility. The present test offers quantitation and could have potential use in following the appearance of new genetically controlled specificities, for example, in induced or spontaneous tumour formation.

A further application of the test is in the determination of iso-antigens by inhibition of the lytic reaction. Methods similar in principle have been used before[27,29], but all these depended on inhibition of a visually estimated effect, with concomitant lack of precision. By choosing amounts of antiserum which, in the absence of inhibitor, will give greater than and less than 50 per cent lysis, the effect of increasing amounts of inhibitor on the 50 per cent titre of an antiserum can be determined by the use

of von Krogh analysis or the log log plot of Weinrach *et al.* The 50 per cent titre is used because this is the region of the sigmoid lytic response most sensitive to small changes in antiserum concentration. Fig. 5 illustrates the inhibition of lysis of labelled lymphocytes caused by the addition of unlabelled, but otherwise identical, lymphocytes. Inhibition by lymphocytes from the strain of mouse providing the antiserum is only 2 per cent that of lymphocytes from the strain of mouse providing the target cells, thereby demonstrating the specificity of the system.

It should be borne in mind that tissue transplantation is not always accompanied by the occurrence of detectable circulating antibodies, and for sensitivity and specificity the biological assays such as skin grafting and tumour grafting cannot, as yet, be improved on, but they are imprecise, and the present assay possesses sufficient advantages to merit its use in cases where histocompatibility differences give a humoral response. Preliminary studies of iso-immunity in dogs[30] and chickens[31] with a similar assay using peripheral blood leucocytes as target cells appear promising.

IDENTITY OF *Pseudomonas* CYTOCHROME OXIDASE WITH *Pseudomonas* NITRITE REDUCTASE

By Dr. T. YAMANAKA

Department of Biology, Faculty of Science, University of Osaka, Japan

IT is well known that, in the living cell, cytochrome oxidase catalyses the reaction of molecular oxygen with electrons liberated from various substrates. In most animal tissues, in many plant tissues and in some micro-organisms, cytochrome *a* is known to function as the cytochrome oxidase[1]. On the other hand it is generally assumed[2] that cytochrome a_2 functions as a cytochrome oxidase in many micro-organisms which do not possess cytochrome *a*. Indeed, from several bacteria, all of which contain cytochrome a_2, Barrett[3] extracted and partially purified a green hæmin, which he designated as hæmin a_2. However, cytochrome a_2 itself has not been isolated from bacteria which are thought to possess it.

It is known that nitrite reductases are present in micro-organisms and that they are metal enzymes[4–7]. However, they have not been exhaustively purified so their chemical entities are unknown.

In this laboratory we have purified and crystallized the cytochrome from *Pseudomonas aeruginosa* which was formerly called *Pseudomonas* cytochrome$_{GB}$ and later named *Pseudomonas* cytochrome oxidase[8–15]. Although the cytochrome a_2 with only hæm a_2 as its prosthetic group has not been isolated, *Pseudomonas* cytochrome oxidase has hæm a_2 and hæm *c* in the molecule. *Pseudomonas* cytochrome oxidase not only possesses the general properties of cytochrome oxidase but also acts as a nitrite reductase[16,17], and is apparently the same entity as *Pseudomonas* nitrite reductase[18]. This cytochrome oxidase is, therefore, interesting both from physiological and enzymological points of view.

Enzymatic Properties

Pseudomonas cytochrome oxidase shows the general properties of a cytochrome oxidase, that is, it oxidizes ascorbate, hydroquinone, the reduced form of *Pseudomonas* blue protein (a copper protein)[19,20] and the reduced form of *Pseudomonas* cytochrome *c*–551 (ref. 21) which is known to function in the organism just as cytochrome *c* does in animal tissues[22]. These reactions are strongly inhibited in the presence of cyanide and carbon monoxide. The enzyme is extremely labile in the presence of a trace of hydrogen peroxide[23].

One mole of the enzyme can oxidize 2,400 moles of the reduced *Pseudomonas* cytochrome *c*–551 per minute under aerobic conditions at 37° C[13]. This turnover number corresponds to 600 moles of oxygen consumption, and consequently to 13,440 litres oxygen consumption per mole of the enzyme per min at 37° C. Although the reduced form of *Pseudomonas* cytochrome *c*–551 is rapidly oxidized by the enzyme, that of mammalian cytochrome *c* is scarcely oxidized[13]. This biological specificity of the enzyme is useful for detecting delicate differences in the molecular structures of various forms of cytochrome *c*.

Pseudomonas cytochrome oxidase acts as a nitrite reductase[16,17]; it reduces nitrite to nitric oxide with reduced *Pseudomonas* cytochrome *c*–551 as the electron donor, under anaerobic conditions.

$$\text{cytochrome } c\text{–}551\,(Fe^{++}) + NO_2^- + H^+ \xrightarrow{\text{Pseudomonas cytochrome oxidase}} \text{cytochrome } c\text{–}551\,(Fe^{+++}) + NO + OH^-$$

One mole of the enzyme reduces 4,000 moles of nitrite to nitric oxide per min at 37° C under anaerobic conditions. This reaction is strongly inhibited by cyanide but not by carbon monoxide. The behaviour of the enzyme with these inhibitors is the same as that of whole cells of *Pseudomonas aeruginosa*[18]. Thus, *Pseudomonas* cytochrome oxidase seems to be the same entity as the nitrite

reductase functioning in this organism. This will be discussed further in this contribution. *Pseudomonas* cytochrome oxidase is to be named *Pseudomonas* cytochrome *c*–551: nitrite, O_2 oxidoreductase (*EC* 1·9 group)[18].

Spectral Properties

As described already, *Pseudomonas* cytochrome oxidase has two hæms in the one molecule. Therefore, it shows a very complicated absorption spectrum[13,14]. This spectrum has peaks at 280 mμ, 412 mμ, 525 mμ and 635 mμ in the oxidized form, and at 420 mμ, 523 mμ, 549 mμ and 554 mμ in the reduced form. In the latter form, there is a bump at 460 mμ which is the γ-band due to hæm a_2, and at *p*H 7·0 the peak at 635 mμ of the oxidized form changes to two peaks at 629 mμ and 652 mμ. The ratio of $A_{\gamma}^{\text{reduced}}/A_{\alpha}^{\text{oxidized}}$ is 2·28 at *p*H 7·0 (A = absorbancy). Therefore, the γ-band of cytochrome a_2 has a very low absorbancy compared with α-band, as reported by other workers[24]. The spectrum of the dithionite-reduced enzyme in the red region varied considerably with the *p*H (Table 1). When ascorbate was used in place of dithionite to reduce the enzyme, an asymmetrical peak at 645 mμ appeared, whereas the corresponding γ-band was at 460 mμ. With ascorbate, there is no such variation in the position of the α-band of hæm a_2 with *p*H as seen with dithionite. From the above facts it is concluded that there is no parallelism between the positions of the peaks at 460 mμ and in the red region, although it is evident, as described here, that the two peaks are caused by hæm a_2. In the presence of cyanide, carbon monoxide and nitric oxide, the spectrum of the reduced enzyme in the red region is strongly affected, as shown in Table 1.

Table 1. Effect of *p*H, Cyanide, Carbon Monoxide and Nitric Oxide on the Absorption Spectrum of *Pseudomonas* Cytochrome Oxidase

Reagent added	*p*H	Position of peak (mμ) γ-band*	α-band*
None	7·6	460	655
	7·0	460	629, 652
	5·6	460	625
CN^-	7·0	443, 472	627
CO	7·0	—	622, 658
NO	7·0	—	665

*Peaks due to hæm a_2.

Prosthetic Group

When *Pseudomonas* cytochrome oxidase is treated with acid acetone, hæm a_2 is extracted into the acetone whereas hæm *c* is precipitated with the protein moiety[15]. The hæm a_2 is easily separated as aqueous solution from the acetone by adding sodium hydroxide. The aqueous solution of hæm a_2 has absorption peaks at 405 mμ and 684 mμ in the oxidized form (that is, hæmatin a_2) and at 453 mμ and 626 mμ in the reduced form. These peaks change greatly on the addition of various reagents (Table 2). From the protein fraction precipitated by acid acetone treatment, hæm *c* can be split off as hæmatohæm by the silver sulphate method[25].

Reconstitution of the Enzyme

When hæm a_2 and the protein fraction described above are mixed, an enzyme which is very similar to the original enzyme can be reconstituted[26,27]. The reconstituted enzyme has both cytochrome oxidase and nitrite reductase activities, and these activities are both about 50 per cent of those of the original enzyme. Although the reconstituted enzyme is not purified, as it has not been obtained in sufficient amounts to be subjected to chromatography, it can be predicted that it will show the same activity as the original enzyme. It seems likely that in the 50 per cent of the reconstituted enzyme hæm a_2 combines with the protein fraction in abnormal positions, perhaps inverted in position.

Table 2. Absorption Peaks of Hæm a_2 and its Derivatives

Reagent	State	Position of peak (mμ) γ-band	α-band
None	Oxidized	405	684
None	Reduced	453	626
Pyridine	Reduced	432	620
CN^-	Reduced	449, 480	632
NO	Oxidized	407	645
NO	Reduced	408, 436	625
CO	Reduced	413, 440	644

Table 3. Relative Activities of the Reconstituted Enzyme and Various Enzyme Models

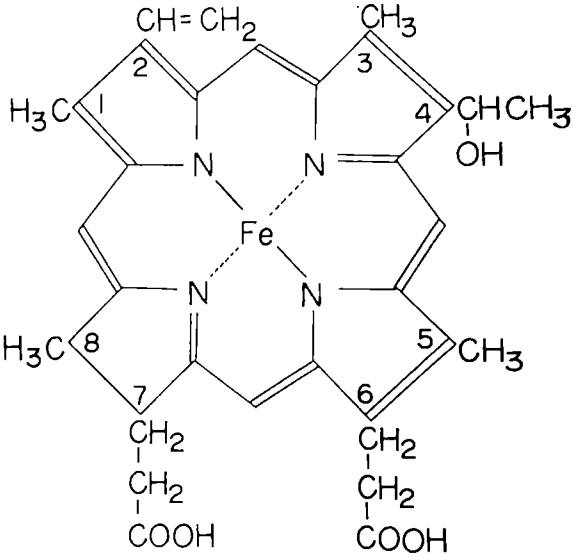
	Cytochrome oxidase activity (%)	Nitrite reductase activity (%)
Hæm a_2	100	100
Hæm a_2-derivative*	12	24
Fe-chlorophyllin	22	46
Protohæm	22	50
Hæmatohæm	13	24
Hæm *a*	4·9	7·4

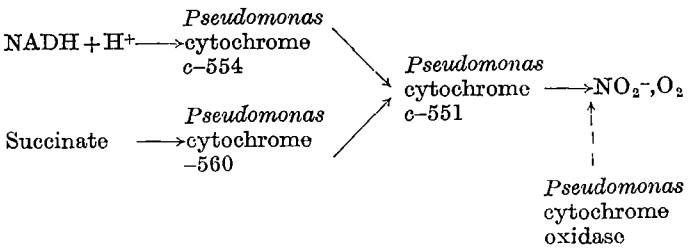
*A hæm derived from hæm a_2 by removing extra hydrogen atoms at positions 7 and 8.

The protein fraction which is made by splitting off the hæm a_2 is insoluble at neutral *p*H. When the protein fraction is combined with the hæm a_2 it becomes soluble. Thus, the hæm a_2 in this enzyme plays an important part both in solubilizing the protein fraction and in activating it. When various hæms are used in place of hæm a_2, various enzyme models can be constructed (Table 3). From the activities of these enzyme models, it is concluded that two extra hydrogen atoms at positions 7 and 8, and the vinyl group at position 2 of hæm a_2, are essential for enzymatic activity. *Pseudomonas* cytochrome oxidase is the first hæmoprotein with hæm a_2 which has been reconstituted from its hæm and protein fractions.

Biological Significance

As described here, *Pseudomonas* cytochrome oxidase has two enzymatic activities, as cytochrome oxidase and as nitrite reductase, and it seems that this enzyme is responsible for the nitrite reductase activity in the cells of *P. aeruginosa*, because it is obtained only from cells cultivated in the presence of nitrate[18]. Cells cultivated in the absence of nitrate lack nitrite-reducing activity whereas they reduce nitrate to nitrite[22]. Although this enzyme contains no copper[11], its biosynthesis is greatly stimulated by addition of copper sulphate to the culture medium. The idea that *Pseudomonas* cytochrome oxidase is the same entity as the nitrite reductase functioning in the living cell is supported by the observation by Walker and Nicholas[29] that nitrite reductase of





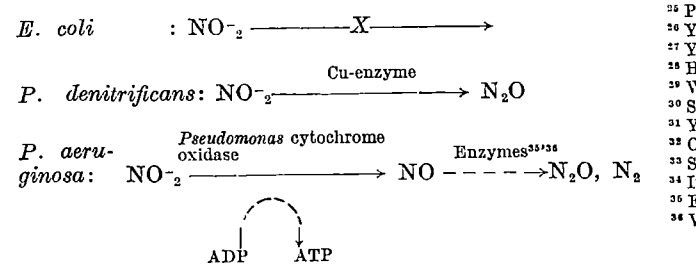


Fig. 1. The structural formula of hæm a_2 (ref. 3)

P. aeruginosa which has been partially purified shows an absorption spectrum very similar to that of *Pseudomonas* cytochrome oxidase. Nevertheless, it cannot be denied that this enzyme participates in the oxygen consumption of cells cultivated in the presence of nitrate, because it possesses the general properties of cytochrome oxidase. The nitrite-reducing system of *P. aeruginosa* seems to be as follows[17,22]:

Evolution of the Nitrite-reducing System

In denitrifying bacteria, it is known that nitrate can act as the ultimate electron acceptor instead of oxygen under anaerobic conditions. This phenomenon is called nitrate respiration[30]. Indeed, it is demonstrated in cell-free extracts of pseudomonads that oxidative phosphorylation occurs, coupled with anaerobic nitrate reduction[31,32]. Nitrate respiration seems to be a more primitive respiration mechanism than oxygen respiration (that is, common respiration). But as the nitrite produced by reduction of nitrate is very poisonous to the organism, it has to develop a mechanism to eliminate nitrite. Thus the nitrite-reducing system might have appeared after the nitrate-reducing one. For example, we can consider three kinds of nitrite-reducing systems of dissimilar types, namely, those of *Escherichia coli*, *P. denitrificans* and *P. aeruginosa*. *E. coli* can scarcely reduce nitrite, whereas, from *P. denitrificans*, a copper enzyme has been purified[33,34] which reduces nitrite to nitrous oxide. It seems very likely that this nitrite reductase is more primitive than that of *P. aeruginosa*, namely, *Pseudomonas* cytochrome oxidase, because it is not a hæmoprotein. It may be that the nitrite-reducing system of *P. denitrificans* is effective only in elimination of nitrite, whereas that of *P. aeruginosa* participates in ATP formation by utilizing the energy obtainable in consuming nitrite. As the nitrite-reducing system of *P. aeruginosa* comprises a highly developed cytochrome system, as described here, it may have been able to participate in oxygen respiration as soon as molecular oxygen appeared on the Earth.

Pseudomonas cytochrome oxidase is the same entity as the nitrite reductase functioning in *P. aeruginosa*. Thus, *Pseudomonas* nitrite reductase is a cytochrome which has two hæms, namely, hæm a_2 and hæm c, in the one molecule. It has been obtained in a crystalline state. It possesses no copper, but copper salts are necessary for its biosynthesis. It reduces nitrite to nitric oxide with reduced *Pseudomonas* cytochrome c–551 as the electron donor. The nitrite-reducing system of *P. aeruginosa* is composed of a highly developed cytochrome system, and this fact suggests that ATP formation coupled with nitrite reduction occurs in this organism. Thus, the nitrite-reducing system of *P. aeruginosa* is very similar to the typical electron transport system which participates in normal respiration in higher organisms. The fact that *Pseudomonas* nitrite reductase possesses the general properties of cytochrome oxidase suggests strongly that oxygen respiration may have evolved from a nitrate-respiration system such as that seen in *P. aeuroginosa*. It is also very interesting that the prosthetic group of *Pseudomonas* cytochrome oxidase, hæm a_2, is a derivative of chlorin, that is, that the structure of hæm a_2 is similar to that of chlorophyll.

I thank Prof. K. Okunuki for advice.

ENZYMATIC BASIS OF THE RESPIRATORY STIMULATION DURING PHAGOCYTOSIS

By Dr. ROBERT H. CAGAN and Prof. MANFRED L. KARNOVSKY
Department of Biological Chemistry, Harvard Medical School, Boston, Mass.

SEVERAL metabolic concomitants of phagocytosis have been observed[1]. One striking phenomenon in polymorphonuclear leucocytes (PMN) is an increased respiration during particle uptake[2,3] which has been shown to be insensitive to 1 mM cyanide. It was concluded that this increase in respiration is not cytochrome-linked[3]. Accompanying the respiratory increase in PMN is a 7-fold, cyanide-insensitive stimulation of the con-

version of glucose carbon-1 to carbon dioxide. The energy for phagocytosis in PMN appears to come from glycolysis rather than from oxidative phosphorylation, judging from results obtained anaerobically and with various metabolic inhibitors[1,3].

To explain the respiratory stimulation in PMN that is insensitive to cyanide, it has been postulated[4] that two key enzymes, a cyanide-insensitive NADH oxidase and NADPH-linked lactate dehydrogenase, are involved. The following hypothesis was offered[4]: during uptake of particles, the cyanide-insensitive NADH oxidase is activated, which accounts for the increased oxygen uptake. Some pyruvate from glycolysis is then available in excess of the NADH available to convert it to lactate. An NADPH-linked lactate dehydrogenase catalyses the conversion of this pyruvate to lactate and this reaction increases the available NADP. NADP has been shown to be a rate-limiting factor for the hexosemonophosphate shunt in leucocytes[5], and the rate of reoxidation of NADPH is therefore important in the stimulation of this pathway. Postulation of the rather indirect mechanism above was necessary because the oxidase for reduced pyridine nucleotides that was found in PMN was about 10-fold more active with respect to NADH than toward NADPH, and transhydrogenase, measured by conventional means, was not found[4,6].

Quastel *et al.*, who used dialysed homogenates of PMN, have reported that these cells contain an NADPH oxidase rather than an NADH oxidase, and that it is the former enzyme that participates in changing the metabolic pattern during phagocytosis[7,8]. It should be emphasized that their experiments were conducted in the absence of cyanide. Recently, however, Roberts and Quastel[9] reported that the enzyme they had been examining (NADPH oxidase) is inhibited by 1 mM cyanide, and is probably, in fact, peroxidase.

It appears that two different enzymatic reactions are under discussion by Quastel's laboratory and our own: (*a*) A cyanide-sensitive, manganese-stimulated oxidation of reduced pyridine nucleotides catalysed by peroxidase. It is well known that peroxidase is capable of such activity[10,11]. As shown here and by others[12,13], peroxidase is localized in the granules of leucocytes. (*b*) A cyanide-insensitive oxidation of reduced pyridine nucleotides catalysed by an enzyme is under study in our laboratory.

We shall attempt in this article to clarify two matters: (1) that of the characteristics of oxidases for reduced pyridine nucleotides in PMN; (2) that of the cytological localization of the cyanide-insensitive enzyme (NADH oxidase).

The abilities of several different types of preparation from guinea-pig PMN to catalyse the oxidation of reduced pyridine nucleotides are summarized in Table 1, and it may be seen that homogenates or the supernatant fraction therefrom have the ability to oxidize NADH faster than NADPH, in contrast to the findings of Quastel *et al.*[7,8]. In the absence of cyanide, Mn^{++} or ethanol were stimulatory as has been pointed out by Iyer and Quastel[8]. These effects were absent in the presence of cyanide, under which conditions there was little or no activity toward NADPH. On the other hand, the activity of the enzyme in the supernatant fraction was virtually unaffected by cyanide.

None of the preparations we have used, in either the absence or presence of cyanide, showed the specificity reported by Quastel *et al.*[7,8]. We have tested several different lots of the reduced pyridine nucleotides (Sigma Chemical Co. and Pabst Laboratories) using freshly prepared solutions. Contamination of the cell preparations with monocytes was considered, since the period (30 h)[7] used by the Canadian group for eliciting the sterile peritoneal abscess could conceivably yield preparations with many monocytes[15]. However, a homogenate of monocytes did not show the preference for NADPH reported by Quastel *et al.*[7,8]. Possibly the NADH they used contained the inhibitor reported by Fawcett *et al.*[16].

Table 1. NADH and NADPH Oxidase Activities in Preparations from PMN Homogenate

Exp. No.	Preparation*	Substrate	Addition or treatment*	Activity† −KCN	Activity† +KCN
1	Whole homogenate	NADH	—	—	3·0
		NADH	*FT*	—	2·9
		NADPH	—	—	0·9
		NADPH	*FT*	—	0·9
2	Whole homogenate dialysed	NADH	—	2·4	2·6
		NADH	Mn^{++}	5·4	2·8
		NADH	Ethanol	6·2	2·1
		NADPH	—	0·8	0·0

3*A*	Homogenate dialysed	NADH	—	7·0	—
		NADPH	—	0·0	0·0
		NADPH	Mn^{++}	7·1	0·0
B	Homogenate dialysed	NADH	—	5·0	2·7
		NADH	Mn^{++}	10·4	1·7
4	Supernatant fraction	NADH	—	1·31	1·14
		NADPH	—	0·35	0·31

* Experimental conditions. Exp. 1. Cells (20 per cent suspension) homogenized 3 min in alkaline isotonic KCl (ref. 14) with a motor-driven 'Teflon' pestle in a glass tube. *FT* denotes freezing (−14 to −16° C) and thawing (37° C) twice prior to assay. Cells were PMN (ref. 15). Exp. 2. Whole homogenate as in Exp. 1, also dialysed 17 h according to Iyer and Quastel (ref. 8). Exp. 3. Homogenate prepared according to Quastel *et al.* (refs. 7 and 8). This included freezing and thawing, and dialysis. 3*A* and 3*B* run on subsequent days with enzyme stored overnight at 5° C. Exp. 4. Supernatant fraction after centrifuging homogenate at 30,000*g* for 1 h.

† Results of Exps. 1, 2 and 3 expressed as μl. O_2 consumed per 30 min and mg protein. Those of Exp. 4 expressed as mμmole reduced pyridine nucleotide oxidized per minute and mg protein. Enzyme assays: Exps. 1 and 2. Manometric assay, 37° C, *p*H 7 (0·03 M phosphate buffer) with air as gas phase. NADH or NADPH at $2{\cdot}5 \times 10^{-3}$ M. $MnCl_2$ at $5{\cdot}0 \times 10^{-4}$ M and ethanol at $4{\cdot}5 \times 10^{-3}$ M. Exp. 3. Manometric assay, 37° C, *p*H 5·5 according to Iyer and Quastel (ref. 8). Exp. 4. Spectrophotometric assay, by decrease in absorbance at 340 mμ; 25° C, *p*H 7 (0·03 M phosphate buffer), NADH or NADPH at $1{\cdot}7 \times 10^{-4}$ M. Where KCN was used, it was present at 1 mM

The enzyme from the supernatant fraction was purified about 10-fold by precipitation with ammonium sulphate (30–60 per cent saturation), dialysis and column chromatography on DEAE-cellulose. Such preparations are essentially free of lactate dehydrogenases and show no stimulation of either NADH or NADPH oxidase activity by Mn^{++}. At this stage the enzyme is virtually inactive toward NADPH. Its *p*H optimum is about *p*H 5, at which it has roughly double the activity shown at *p*H 7. Preliminary experiments with this enzyme show that in the presence of 1 mM potassium cyanide, 1 mole of oxygen is consumed per mole of NADH oxidized, and hydrogen peroxide is presumably formed. Evidence from fluorimetric investigations[17] of the enzyme preparation at various stages of purity suggests that it contains FAD. Preliminary experiments with polyacrylamide gel electrophoresis indicate that the enzyme may be separated from other proteins and it can be located on the gel by a diaphorase reaction with nitro blue tetrazolium and NADH[18]. Elution of the enzyme from such gels has been achieved with a further increase in purity, but as yet in low yields.

The distribution of the oxidase among subcellular fractions was compared with that of a number of known enzymes of the characteristic granules of PMN. As shown in Table 2, the hydrolytic enzymes and peroxidase are found predominantly in the granule fraction, in agreement with previous reports[12–14]. Cyanide-sensitive NADH oxidase follows the same pattern. On the other hand, the cyanide-insensitive NADH oxidase, measured either spectrophotometrically or manometrically, is found largely in the supernatant fraction. The possibility that this enzyme was released during the fractionation is remote, in view of the results obtained with the five other enzymes examined.

As a result of these findings, we must modify our previous hypothesis for the mechanism underlying the increase in respiration and direct oxidation of glucose-6-P in PMN when they phagocytose. Previously we suggested[4] that the cyanide-insensitive NADH oxidase is associated with the granule fraction. This stemmed from the fact that some of the enzyme adheres to the granules, from which it may be partially removed by washing, thus giving rise to the impression that it was liberated by freezing

Table 2. DISTRIBUTION OF TOTAL ENZYMATIC ACTIVITIES OF PMN

Component	Fraction* Debris	Granule	Post-granule	Supernatant
Acid phosphatase†	29	57	9	5

β-Galactosidase	8	68	3	21
Peroxidase	23	74	1	1
NADH oxidase				
CN-sensitive‡	20	64	9	7
CN-insensitive‡	27	18	5	51
CN-insensitive§	11	5	11	73
Protein¶	24	24	4	47

* Results are based on recovered enzyme or protein as 100 per cent. Cells homogenized as in Table 1 (Exp. 1). Homogenate spun at 240*g* (10 min) and the pellet resuspended and rehomogenized. This homogenate spun at 240*g* (10 min) to obtain the debris fraction. The combined supernatant fractions were spun at 30,000*g* (15 min) to obtain the granule fraction, and then at 100,000*g* (1 h) to obtain the post-granule fraction. The fraction that remained was termed 'supernatant fraction'.

† Hydrolytic enzymes and peroxidase were assayed by standard methods (refs. 19–21) with some modifications.

‡ Spectrophotometric assays as in Table 1. Cyanide-sensitive activity obtained from difference between total and cyanide-insensitive (1 mM KCN) activities.

§ Manometric assays (37° C, *p*H 7) as in Table 1.

¶ Protein determined by the method of Lowry *et al.* (ref. 22).

and thawing[4]. Our previous failure to detect it in the supernatant fraction was due to excessive dilution of this fraction with washings in the course of the fractionation. In the work recorded here we were careful to keep the supernatant fraction as concentrated as possible. Our hypothesis[4] previously involved the release of the oxidase from the granules during phagocytosis, as had been established for the lytic enzymes[23], and its activation. Postulation of such a release of the oxidase is no longer necessary in view of the foregoing distribution investigations. Activation may be the result of a transient increase in intracellular H^+ concentration[1,24], since an increase in lactate occurs during phagocytosis[3,6] and the enzyme has a low *p*H optimum.

In accord with the foregoing results, Rossi and Zatti[25] have reported that, whereas acid phosphatase is increased in the supernatant fraction from phagocytosing cells (indicating release from the granules), no such increase of the NADH oxidase in the supernatant fraction occurs—suggesting that the latter enzyme is not released from granules during phagocytosis. The supernatant fraction in their experiments also exhibited no activity toward NADPH. Their investigations of granule-associated oxidases are not clear, however, since no cyanide was present.

The level of activity of the cyanide-insensitive NADH oxidase determined manometrically at 37° C on whole homogenates is of the order of 5–6 μl. oxygen/h and mg protein at *p*H 7. The respiratory stimulation due to phagocytosis by intact PMN amounts to 244 per cent of the resting level of 2·5 μl. oxygen/h and mg protein[15]. The net increment in respiration during phagocytosis of 3·6 μl. oxygen/h and mg protein is thus readily accounted for by the activity of the cyanide-insensitive NADH oxidase. If the optimal *p*H for this enzyme is taken into account, there appears to be about 3 times as much enzyme present as is required to account for the respiratory increase during phagocytosis.

Our original concept that a cyanide-insensitive NADH oxidase is responsible for the bulk of the respiratory stimulation during phagocytosis by PMN seems tenable in the light of the observations reported. Our first impression that this enzyme is localized in the granules of these cells has been corrected ; it is recovered mainly in the supernatant fraction from cell-homogenates. The existence of the NADH oxidase, its cyanide-insensitivity, and its occurrence in amounts adequate to account for the respiratory stimulation in intact cells, make it unnecessary to invoke the granule-bound peroxidase which is cyanide-sensitive. Roberts and Quastel expressed the opinion that the very large content of peroxidase in PMN might permit its involvement, by release from the granules, even in the presence of cyanide[9] ; but there is no experimental basis for this idea. Further, the work of Hirsch[26] indicates that when degranulation occurs during phagocytosis, the granule contents are discharged into the phagocytic vacuoles. This would raise an additional problem of a morphological nature as to how peroxidase, a component of the granules, might react with reduced pyridine nucleotides in the cytoplasm. This problem was also, of course, implicit in our previous hypothesis[4], and the findings outlined above obviate this consideration.

ATTEMPTS TO DEMONSTRATE A TRANSMISSIBLE AGENT IN KURU, AMYOTROPHIC LATERAL SCLEROSIS, AND OTHER SUB-ACUTE AND CHRONIC NERVOUS SYSTEM DEGENERATIONS OF MAN

By DR. D. CARLETON GAJDUSEK and DR. CLARENCE J. GIBBS, jun.

National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda, Maryland

THIS article is a summary of our programme of work on the possibly infectious ætiology of chronic human central nervous system diseases. It presents negative results, after the first year of observation, of attempts at virus isolation and experimental transmission, particularly in primates, of kuru and amyotrophic lateral sclerosis. Moreover, it briefly describes recently initiated experiments, after only one to two months observation, on sub-acute inclusion encephalitis of the Dawson type and passage of central nervous system tissues from a monkey infected in the U.S.S.R. with human amyotrophic lateral sclerosis material. Because of the increasingly frequent suggestions that a transmissible agent may be involved in the pathogenesis of these diseases[1–10], this progress report on experiments which will not be terminated before five years is in order.

At the time of medical discovery of the kuru focus among the Fore people and their neighbours in the high-

lands of eastern New Guinea, the possibilities of acute infectious, post-infectious, and of chronic persistent infectious ætiology, as well as of an infection-stimulated hypersensitivity state, were all considered[11,12]. The cause of this unremitting and unaltered plague on some 30,000 Melanesian natives, still causing to-day more than half the mortality in the regions of highest incidence, has remained unsolved.

Early in 1957 small laboratory animals, including chick embryos, mice, rats, guinea-pigs and rabbits, were inoculated with suspensions of brain tissue from kuru patients in an attempt to transmit the disease experimentally, or to propagate a micro-organism associated with it. Neuropathological investigations of patients had failed to elicit any definitive histopathological lesions in the central nervous system, such as were commonly associated with viral infections. Furthermore, clinical laboratory investigations of cerebrospinal fluid specimens from kuru patients did not elicit findings such as pleocytosis or elevated protein values common, at least in a high percentage of cases, to all known central nervous system viral infections of man. Patients failed to show febrile reactions at any stage of the disease, no consistent change in erythrocyte sedimentation rate or in the peripheral blood picture was found, and no episode of contact infection was recorded epidemiologically. Thus, acute infectious ætiology seemed unlikely. Nevertheless, brain tissue obtained from kuru patients taken shortly after death was preserved in buffered glycerin or by ice refrigeration and flown to Melbourne, Australia, where isolation attempts were initiated. Some of these specimens were afterwards shipped under dry ice refrigeration to the National Institutes of Health, Bethesda, Maryland, where additional isolation investigations were conducted utilizing small laboratory animals, embryonated chicken eggs, and a variety of tissue and cell cultures prepared from human, animal and avian origins. These early investigations failed to elicit any recognizable or recoverable pathogenic micro-organisms during the three months that the animals remained under observation.

More recently, however, Hadlow[3] has reported that a similarity exists between the neuropathological lesions in sheep with scrapie disease and human beings with kuru. These observations led us to re-evaluate our isolation procedures and laboratory techniques and to reconsider the possibility that an ætiological agent for kuru might be a slow or latent virus with, perhaps, a genetically determined susceptibility, or perhaps, even more speculatively, a temperate virus actually genetically transmitted, acting somewhat like a lysogenic bacteriophage. Indeed, because of the unusual heat stability and alleged genetic transmission in flocks of sheep, the suggestion had often been made that the scrapie agent might be denuded nucleic acids originating from the host genetic apparatus itself, and not a complete virus particle as commonly encountered in virology[13]. Although such a postulate would help to explain the lack of detectable antibody in scrapie disease in sheep, more detailed investigation of heat inactivation of the agent and its enzyme sensitivity, including the failure to inactivate its infectivity with deoxyribonuclease and ribonuclease, and the rather conventional virus behaviour of the pathogen, have convinced most workers that the scrapie agent is a more orthodox animal virus[14,15].

Beginning in 1962, long-term investigations aimed at observing primates for five years or more, and smaller animals and tissue cultures for as lengthy periods as possible, were initiated in our laboratories. Table 1 summarizes the isolation investigations now in progress on specimens of central nervous system tissues from patients who had died of kuru, as well as experiments on amyotrophic lateral sclerosis and Parkinsonism-dementia syndrome associated with amyotrophic lateral sclerosis on Guam. Although only one chimpanzee (*Pan satyrus*) has, in general, been inoculated with the material from a single patient, other primates, rhesus (*Macaca rhesus mulatta*), cynomolgus (*Macaca cynomolgus irus*), and African green (*Cercopithecus aethiops*) monkeys, have been inoculated in groups varying from a few to a dozen with inoculum from a single patient. In addition, groups of large numbers of new-born and weanling mice of several strains, hamsters and guinea-pigs, and primary and stable tissue culture lines have been inoculated with serially diluted brain suspension (in phosphate buffered physiological saline, *p*H 7·4) prepared immediately before inoculation from freshly thawed tissue. Most primates have received inocula of 0·2 ml. intracerebrally and 0·2 ml. intravenously, while smaller animals have been injected with varying amounts of diluted and undiluted materials in a variety of routes.

The earliest of these long-term investigations were started in small laboratory animals inoculated in October 1962. In January 1963 a 10 per cent suspension of brain tissue from the right temporal region of the brain, obtained 4·5 h after death from a patient who had died of kuru, was inoculated intracerebrally and intravenously into a young (less than 6 months of age) rhesus monkey; this suspension was also inoculated into small laboratory animals and tissue cultures. After 20 months of close observation none of the animals have developed any evidence of neurological disorders, nor has a viable agent been isolated in them; tissue culture investigations likewise revealed no cytopathological effect or evidence of chronic carrier state.

As the scope of our programme became enlarged and intensified in early 1963, greater emphasis was placed on the selection and preservation of specimens, on the range of experimental hosts used, and on improved virological and tissue culture procedures for successful isolations. Thus, for example, brain and visceral tissue specimens have been obtained from kuru patients in New Guinea within 2 h of death. These tissues were immediately frozen in liquid nitrogen and shipped by air in liquid nitrogen to the National Institutes of Health, where portions were rapidly thawed, ground to 20 per cent suspensions in phosphate buffered saline solution (*p*H 7·4) and inoculated into test animals, primarily primates. Specifically, 6 chimpanzees, 32 rhesus, 25 cynomolgus and 10 African green monkeys have been observed for 2–19 months after inoculation with kuru brain material without developing signs of disease. In all, brain from seven different kuru patients has been used in these primate inoculations. These inocula have also been put into the following tissue culture lines: routinely into primary and stable rhesus kidney, *BS-C*-1 green monkey kidney, human amnion, Chang liver, chick embryo, mouse embryo, *Hep*-2, *L*-cells and HeLa; on occasion into human embryo kidney, primary pig kidney and pig choroid plexus. No cytopathogenic effect has been observed. Attempts are also being made to culture viable cells *in vitro* from liquid nitrogen preserved tissue for the purpose of determining cell morphology and abnormality, as well as for isolations of viruses.

We have, furthermore, also been interested in the possibility that transmissible agents may be involved in the pathogenesis of a wide range of chronic progressive neurological diseases. Among these the foci of amyotrophic lateral sclerosis and the related Parkinsonism-dementia syndrome in extremely high incidence in the Chamorros population on the Island of Guam is of particular interest[16,17]. In these indigenous Micronesians amyotrophic lateral sclerosis attains a prevalence some one hundred times greater than that observed in the United States, Europe, or Japan. We are, thus, searching for a possible transmissible agent in these diseases; the brain tissue from Guamanian amyotrophic lateral sclerosis and Parkinsonism-dementia patients has been collected, preserved, and processed, as has been described for kuru. So far we have inoculated a total of 6 chimpanzees and 46 monkeys with brain material from five Guamanian patients with amyotrophic lateral sclerosis

and from three with the Parkinsonism-dementia syndrome. These animals have been observed for from 2 to 14 months and no illness attributable to the inoculations has appeared among them.

In addition, brain tissue from a surgical biopsy of one patient with sub-acute inclusion encephalitis of Dawson type has recently been inoculated into one chimpanzee and four monkeys. Finally, a 20 per cent (w/v) suspension of brain and cord material from a second passage rhesus monkey suffering from experimentally induced motor neurone disease has been inoculated intracerebrally and intraperitoneally into 10 rhesus monkeys in our laboratory. This material, supplied by Dr. L. A. Zilber of Moscow, is from one of the second passage monkeys that developed motor neurone disease resembling amyotrophic lateral sclerosis clinically and pathologically following primary inoculation with human brain tissue from a patient with amyotrophic lateral sclerosis[6]. Disease first appeared three years after primary inoculation. Of course, confirmation of this reputed transmission of amyotrophic lateral sclerosis from man to primate is necessary and, furthermore, there is as yet no way of establishing that a transmissible agent causing motor disease in primates is the ætiological agent of motor neurone disease in man.

In spite of the negative findings in the past in search for micro-organisms, especially viruses, as the causative agents of chronic neurological diseases, the possibility of infectious ætiology must now be re-evaluated in the light of newer concepts of latency and masking of viral activity. Viruses known to cause chronic degenerative diseases of the central nervous system in animals, such as scrapie and visna of sheep, have not, as yet, been clearly implicated in any disease in humans, though neutralizing substances to visna virus have been reported in human sera[10], and in at least two instances reports have been made suggesting scrapie-like illness in sheep inoculated with tissues of the central nervous system from patients with sub-acute encephalitis[7] and acute disseminated sclerosis[9]. Furthermore, the virus causing Aleutian disease in mink has recently been suggested as the cause of a case of encephalitis in man[8]. Chumakov has reported on one occasion the isolation of Russian spring-summer encephalitis virus from the brain of a patient suffering from Kozhevnikov's epilepsy, a chronic convulsive syndrome which has often been suggested to be a late effect of this virus infection[2].

The Russian workers have also suggested the possibility that Vilyiusk encephalitis, a chronic degenerative central nervous system disorder of Iakutsk people in Siberia, is of viral ætiology[4,18,19]. In neither of these cases is a viral ætiology established, however. In fact, the relationship of the known scrapie, visna, and Aleutian disease in mink viruses to any of the chronic degenerative nervous system diseases of man, as well as the relationship of these human diseases one to another, as, for example, between amyotrophic lateral sclerosis and Parkinsonism-dementia on Guam, and between these syndromes and similar syndromes in America and Europe, cannot be established even if a transmissible virus is located from them, without a specific diagnostic test for the agents. Thus, we are also at present working on the production of hyperimmune animal sera to various particulate and macromolecular tissue fractions of human brain tissue from the diseases under investigation, as well as of tissue from scrapie-infected animals. These antisera may eventually serve as disease specific reagents in neutralization, complement fixation, fluorescent antibody, hæmagglutination-inhibition, and other serological tests which will be essential in establishing a micro-organism as a cause of any of these illnesses.

HETEROGENEITY IN SEGREGATION DATA FROM WHEAT CROSSES

By Dr. N. H. LUIG

Department of Agriculture, University of Sydney

In Soviet papers on plant genetics the claim is frequently made that heritability of characters is greatly influenced by external conditions. Aizenstat[1] found that the amount of pollen, the age of the pollen and the physiological status of the florets were important. Pollination of the first and last floret led to more patroclinous progeny, and, as a rule, with increasing age of the gametes their ability to transmit the characters they carried diminished. More recently, Allard[2] in the United States has found that recombination values in the lima bean, *Phaseolus lunatus* L., varied according to the time of sowing, the time of gathering, and the direction in which selection was practised. Certain aspects of the work recorded here are very similar to the aforementioned and the most significant one is the heterogeneity of data.

In an earlier publication[3] it was shown that differential transmission of gametes in wheat occurs, and it was suggested that the Gabo-type resistance to wheat stem rust, *Puccinia graminis* Pers. var. *tritici* (Eriks. and Henn.), previously thought to be due to the action of two linked dominant complementary factors, and the 'Mentana'-type resistance to wheat leaf rust, *Puccinia recondita* Rob. ex Desm., were due to single dominant factors. A similar conclusion was reached by Sears and Loegering[4]. Both resistances are carried on chromosome 6*B* (*X*) and were found to be very closely linked[3].

A main feature of the previous report[3] was the heterogeneity in segregation ratios obtained in different crosses involving the two factors. This article extends observations on heterogeneity between crosses and shows that heterogeneous data are obtained within crosses when examining different F_2 families, and also within single F_1 plants when testing seed of individual ears.

In this work a second factor besides that from 'Mentana' for resistance to leaf rust is also introduced, namely, the factor which was transferred from *Aegilops umbellulata* to 'Chinese Spring' wheat by Sears, the derivative being named 'Transfer'. Like the other two factors it is located on chromosome 6*B*. In Table 1 are listed results of several crosses (in many instances reciprocal) which did not fit a single factor segregation.

The aberrant F_2 results shown in Table 1 undoubtedly represent a whole range of different ratios. Moreover, when the F_3 generation was examined, ratios within crosses differed even more widely and ranged from a 15 : 1 to a 0·4 : 1. F_3 segregation ratios which went beyond this range were found to be the result of either chromosomal aberrations or outcrossing.

In the cross ('Transfer' × 'Kenya 1483') the transmission ratios for the factor for leaf rust resistance and the factor *Sr*11 were similar (Table 1) and cross-over types were rare, but there was a significant deficiency in number in the heterozygous class. The high fertility of the ears tested combined with the high germinability of the F_2 seeds did not suggest differential zygotic viability. A hypothesis which assumes on the male side pollen abortion coupled with recombination and on the female side differential transmission proves insufficient to explain these results. Selective conjugation during fertilization, however, could account for the data.

Further, a highly significant intra-plant heterogeneity (P = 0·01–0·001) in both crosses involving 'Kenya 1483' was found when separate ear progenies of individual F_1 plants were tested. Again, this was mainly due to variation in number in the heterozygous class.

In the crosses ('Chinese Spring' × 'Gabo') and ('Chinese Spring' × 'Yalta') and their reciprocals, data from different F_2 families were doubtfully homogeneous. However, in results presented by Driscoll[5] involving similar crosses using monosomic lines of 'Chinese Spring', heterogeneity is apparent if the very small families are removed.

In 1961 two different explanations for the distorted ratios were suggested. Sears and Loegering[4] invoked a pollen-killing gene, *Ki*, on chromosome 6*B* in 'Chinese Spring', which they claimed was responsible for a complete removal of all gametes carrying the recessive allele, *ki*. I myself[6], on the other hand, found a high degree of lagging of chromosomes in F_1 plants of crosses which gave distorted segregation ratios. A detailed study of meiosis in F_2 plants of the cross ('Mentana' × 'Yalta') revealed that the univalent frequency was greatest (more than 20 per cent tetrads with micronuclei) in plants heterozygous for the factors for stem-rust and leaf-rust resistance. Since no cross-over types combining the two resistances were obtained among 750 F_3 lines, and since Heyne and Livers[7] have reported a recombination value of 21·7 ± 7·8 per cent for these factors, it could be assumed that chromosome 6*B* was partially asynaptic. Several leaf chimeras involving loss of the dominant allele for rust resistance were found and they could have been the result of somatic elimination of misdivided univalents. Aneuploid segregants occurred so rarely that they would have had no significant effect on the F_2 ratio. Pollen abortion was noticed in several F_1 and F_2 plants, but it was not possible to correlate pollen fertility in the F_2 with subsequent F_3 behaviour to rust. Recently, I have made a detailed study of pollen abortion in F_2 plants of the cross ('Gabo' × 'Mentana'). Approximately 37,500 pollen grains were classified and the percentage of aborted pollen ranged from 0·3 to 93·2 per cent. As in the case of chromosome lagging, plants heterozygous for the factors for rust resistance were far more often found to exhibit a high degree of pollen abortion. However, in several F_3 plants which later gave rise to progeny which segregated in greatly distorted ratios of less than 5 per cent aborted pollen was found. As this article is not concerned with small differences but with gross aberrations, such a small amount of pollen abortion should have been of no consequence.

It was also found that pollen abortion was differentially inherited when seed from individual ears of the same F_1 plant was grown. Thus in three F_2 plants heterozygous for the factors for rust resistance and which originated from the second ear of an F_1 plant, 452 aborted pollen grains were counted among a total of 1,980 (average percentage = 23·9), while seven heterozygous F_2 plants from the seventh ear of the same plant showed only 120 aborted pollen in a total of 2,239 (average percentage = 4·6). Somatic segregation of a cytoplasmic factor, nevertheless, seems unlikely as reciprocal crosses gave the same results when the data of several F_2 families were compared[6].

In a more recent publication[8], Loegering and Sears suggested about 9 per cent recombination between the pollen-killing gene *Ki* and *Sr*11 in the cross ('Chinese

Table 1

‡ McIntosh and Luig (unpublished results).

Spring' × 'Timstein'). Variation in pollen abortion in different samples from the same plant, with a tendency for later samples to approach or reach 50 per cent abortion, was also noticed. In the work recorded here an analysis of the segregation data collected from testing seed from individual ears of F_1 plants of crosses ('Chinese Spring' × 'Gabo') and ('Yalta' × 'Chinese Spring') failed to indicate a tendency for later emerging ears to produce more susceptible F_2 hybrids.

Loegering and Sears[8] also reported that certain varieties showed virtually no pollen abortion in crosses with either 'Chinese Spring' (*KiKi*) or 'Thatcher 6*B*' (*kiki*). In the present work the crosses ('Chinese Spring' × 'Mentana') and ('Gabo' × 'Kenya 1483') gave 43·7 and 40·4 per cent pollen abortion, respectively, although on the assumption of a simple system for pollen abortion these hybrids should have been fully fertile. On the other hand, in crosses in which 50 per cent pollen abortion was expected the actual percentages ranged from 7·7 to 46·2. These results, as well as those of Loegering and Sears[8], clearly demonstrate something more complex than a single dominant allele for pollen abortion.

The character of differential transmission of gametes was inherited from generation to generation. Sometimes the degree of differential transmission was also inherited, especially when the transmission rate for one of the alleles was very low, that is, when female as well as male gametes were involved.

The hypothesis of a pollen-killing gene as the sole cause of differential transmission is rejected because it fails to explain differential transmission of female gametes, the absence of crossing-over between the factors involved, the failure to recover true 3 : 1 segregation ratios resulting from recombination between *Ki* and genes for rust resistance, the various segregation ratios varying from 15 : 1 to 0·4 : 1, the heterogeneity of data, differential transmission in crosses which should have involved only one of the alleles, *Ki* or *ki*, lack of pollen abortion in plants which gave rise to progeny which segregated in greatly distorted ratios, the deficiency in number of heterozygous plants in crosses involving 'Kenya 1483', and various cytological abnormalities mentioned earlier.

Differential transmission of gametes in wheat does not seem to be restricted to chromosome 6*B*. Nyquist[9] has shown that stem-rust resistance in the variety *C.I.* 12633, previously thought to be due to the action of duplicate dominant factors, is controlled by a single factor. This resistance is carried on chromosome 2*B* (XIII), and Nyquist explained the heterogeneous ratios obtained on the basis of differential fertilization. It should be noted, however, that *C.I.* 12633 has 'Chinese Spring' in its pedigree and that percentages of pollen abortion approximating to 50 per cent were observed by Nyquist. As in the present case, the allele from the 'Chinese Spring' background was transmitted at a favourable rate, and for all such reasons a single explanation for the mode of inheritance of factors on chromosomes X and XIII would be more justified.

The work recorded here suggests a complex system operating in wheat which determines the transmission of gametes.

Another as yet unexplained finding is variation for rust reaction in the variety 'Mentana' itself. Genetic and cytological investigations have failed to detect a possible explanation for this, although tripolar spindle formation in the second meiotic division was found with approximately 15 per cent of the tetrads having more than the four nuclei.

This work was supported by a grant from the Wheat Industry Research Council.

PROGESTERONE AND 6-CHLORO-Δ^6-17-ACETOXYPROGESTERONE AS INHIBITORS OF SPERMATOGENESIS IN THE RABBIT

By R. J. ERICSSON and Prof. R. H. DUTT

Department of Animal Science

AND

J. W. ARCHDEACON

Department of Physiology and Biophysics, University of Kentucky, Lexington

THE effect of progesterone and related synthetic compounds on ovulation has been extensively investigated. Evidence from the female indicates that progesterone prevents ovulation by inhibiting release of the gonadotrophic hormone complex[1–3]. Information relative to the action of progesterone on the male reproductive system is limited[4]. Administration of progesterone or compounds with similar biological activity to the male

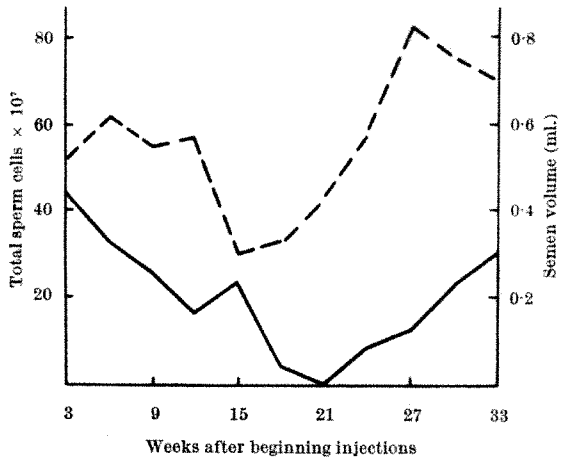

Fig. 1. Changes in semen volume and total number of sperm cells ejaculated by rabbits after progesterone injections. – – –, volume; —, total sperm cells

should result in impairment of spermatogenesis and accessory gland function. Experiments were conducted to determine the effect of progesterone and 6-chloro-Δ^6-17-acetoxyprogesterone (CAP) on semen production and libido in the male rabbit.

Two mature male rabbits were injected subcutaneously with 10 mg of crystalline progesterone in propylene glycol solution every other day for 14 days. Semen for laboratory examination was collected weekly in an artificial vagina. Total volume, volume minus gelatinous material, percentage motile cells, sperm cell concentration and percentage abnormal cells were determined. The only change in any semen characteristics during an 18-week collection period was an increase in the frequency of spermatozoa with protoplasmic droplets. These droplets are not a permanent structure of the mature sperm cell, and when present on ejaculated sperm are considered to indicate immaturity[5]. It is possible that the discharge of stored sperm from the epididymis would allow sufficient numbers in the ejaculate to obscure any interference of spermatogenesis which might result from the 2-week hormone treatment. However, the appearance of protoplasmic droplets indicates an arresting effect on maturation of the sperm cells in the epididymis.

Two additional male rabbits were injected with 10 mg of progesterone every other day for 28 days. One of the rabbits showed reduced libido shortly after beginning of the treatment and refused to serve the artificial vagina unless placed in a breeding position with a teaser doe. Libido in this rabbit gradually returned to normal 8 weeks after beginning of treatment. The remaining male showed no decrease in sex drive during a 33-week collection period. Average total sperm cells and semen volume produced by the two males are shown in Fig. 1. Semen volume and total sperm cells were significantly lower. The lower semen volume in treated males was partially due to a lack of gelatinous material. This gel-like substance, usually present in the semen of the rabbit, was absent for the entire collection period. In two control males, gelatinous material was present in 73 per cent of the ejaculates and constituted 21 per cent of semen volume. The normal function of the glandulæ vesiculares, the glands which are responsible for production of the gelatinous material in rabbit semen[6], was apparently impaired by the progesterone injections. Semen volume of the treated males was significantly lower ($P < 0{\cdot}01$) than controls from the 8th to the 32nd week of the experiment.

Spermatogenesis was also suppressed by the progesterone injections. The treated males produced significantly lower ($P < 0{\cdot}01$) total number of sperm cells than control males from the 15th through the 27th week. By the 19th week of treatment both males were azoospermic, and this condition continued through the 21st week. The lowest numbers of sperm cells occurred in the semen six weeks later than the low point in semen volume (Fig. 1). A delay in deletion of sperm would be expected since cells from the epididymis would serve as a source for a period following inhibition of spermatogenesis.

Testicular biopsies were not taken from the above males due to possible interference with semen collections. However, histological sections prepared from the testis of a male injected with 20 mg of progesterone every other day for 60 days and a control male are shown in Fig. 2. The testis was removed from the treated male 10 days after the last injection of hormone. In contrast to the compact and orderly arrangement of cells in the seminiferous tubules of the control male, the germinal elements in the tubule from the treated male were disorganized and the presence of sloughed cells and debris in the lumen indicated degenerative processes. It was apparent that normal spermatogenic activity in the treated male had been disrupted.

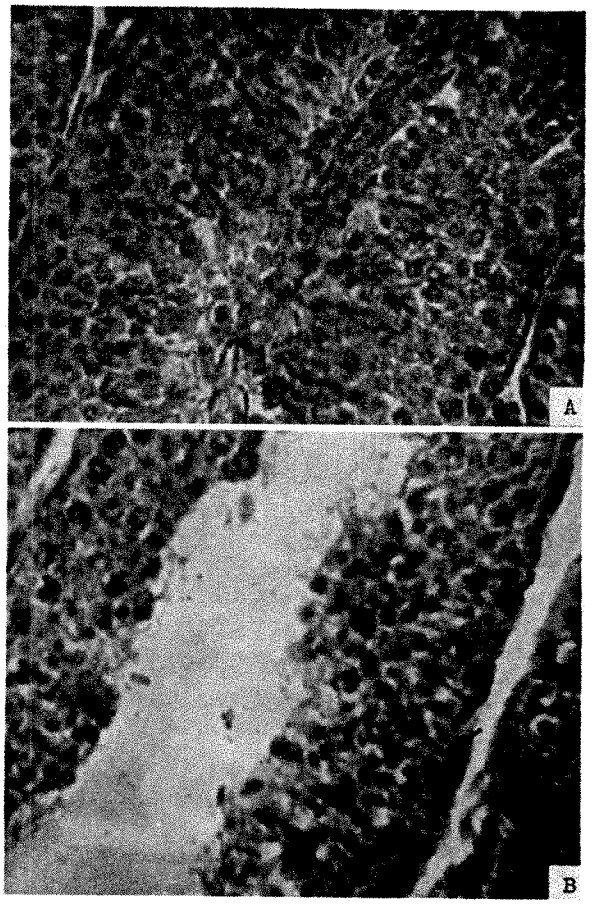

Fig. 2. Photomicrograph of histological sections of rabbit testes (× *c.* 330). *A*, section of seminiferous tubule from control; *B*, section of seminiferous tubule from male injected with 20 mg of progesterone every other day for 60 days

In order to determine the effects on semen production of injecting an orally active progestin, 10 mg of 6-chloro-Δ^6-17-acetoxyprogesterone were injected every other day for 30 days into two male rabbits. Libido was lowered in both males shortly after the injections were started, and continued up to the sixth week, when one male refused to serve the artificial vagina. This male was unilaterally

castrated 11 weeks after the last injection, and histological sections were prepared from the testis. As in the progesterone-treated male, the seminiferous tubules contained cellular debris but no sperm, and the germinal elements were degenerate. The other male continued to serve the artificial vagina, and a few weeks after the end of injections showed a gradual increase in sexual desire. Total sperm cells decreased in the male that continued to produce semen, and from the 19th to the 22nd week his ejaculates were azoospermic. Thereafter, there was a gradual increase in sperm cell numbers. The percentage of motile cells was not significantly affected.

Results from these investigations show that progesterone and certain related compounds which are orally effective as inhibitors of ovulation in the female also interfere with spermatogenesis and accessory gland function in the male rabbit. When progesterone was injected into male rabbits for a short period (2 weeks), the only apparent effect was an increased frequency of protoplasmic droplets on ejaculated sperm. However, when injections of progesterone or CAP were continued for longer periods, the characteristic gelatinous fraction of the ejaculate was not present, and both semen volume and sperm numbers decreased.

The significant lowering of total sperm in semen and the histological appearance of the seminiferous tubules following the longer periods of treatment suggest that spermatogenic activity has been curtailed. The inhibition of spermatogenesis is apparently reversible, since sperm numbers eventually returned to normal level. Further investigations with these or similar compounds on inhibition of spermatogenesis and interference with the normal maturation process of sperm are warranted as potential means of birth control.

We thank the Eli Lilly Co., Indianapolis, Indiana, for supplying the 6-chloro-Δ^6-17-acetoxyprogesterone.

PURIFICATION OF POLIOVIRUS BY DEAE 'SEPHADEX A-25'

By Dr. DAVID J. GIRON and Dr. ALFRED HELIMAN*

Astrobiology Branch, U.S.A.F. School of Aerospace Medicine, Aerospace Medical Division, Air Force Systems Command, Brooks Air Force Base, Texas

NUMEROUS methods have been used for the separation of viruses from extraneous protein attributable to the host. These techniques have primarily involved a combination of ion-exchange chromatography and centrifugation[1,2]. Other techniques have involved the adsorption and subsequent elution of the agent from ion-exchange columns by the gradual change of *p*H or eluate[3]. We wish to report on a rapid method for the purification of Sabin type 1 poliovirus from extraneous tissue culture proteins. This procedure requires only a single manipulation prior to virus purification.

The HeLa cell monolayers were frozen and thawed three times, the lysate centrifuged at 1,000*g* for 10 min and the supernate then purified by ion-exchange chromatography. Utilizing similar elution procedures, three types of ion exchangers were compared as to their effectiveness in purifying virus. The columns consisted of 'ECTEOLA-*SF*' ('Cellex-*E*'), 'Sephadex *G*-25', or DEAE 'Sephadex *A*-25'.

The 'Cellex-*E*' was suspended in M/15 phosphate buffer at *p*H 7·5. The fines were removed and 9 cm × 1·2 cm columns were packed under a pressure of 10 lb./in.^{2}. 'Sephadex *G*-25' was packed as 14 cm × 1·2 cm columns, utilizing M/15 phosphate at 7·5 *p*H. The DEAE 'Sephadex *A*-25' was allowed to swell in water. After removal of the fines, the '*A*-25' was washed in sequence on filter paper by 0·5 N hydrochloric acid; water; 0·5 N sodium hydroxide; and water. It was finally neutralized with 0·5 N hydrochloric acid, suspended in M/15 phosphate buffer at *p*H 7·5, and packed in 14 cm × 1·2 cm columns.

Five ml. of stock poliovirus, prepared as indicated above and having a titre of $4{\cdot}8 \times 10^7$ P.F.U./ml. in HeLa cells, were added to the 'Cellex-*E*' column. Two ml. of this virus suspension were added to the 'Sephadex' columns.

The elution for all columns was carried out at room temperature with M/15 phosphate buffer at *p*H 7·5. The first eluate consisted of 3 ml. Subsequent fractions were collected in 1 ml. quantities at a rate of 1 ml./min. Protein content of the fractions was determined by the Lowry method[4] and virus yield was determined in HeLa cell plaque bottles. Our results indicate that the 'Cellex-*E*'

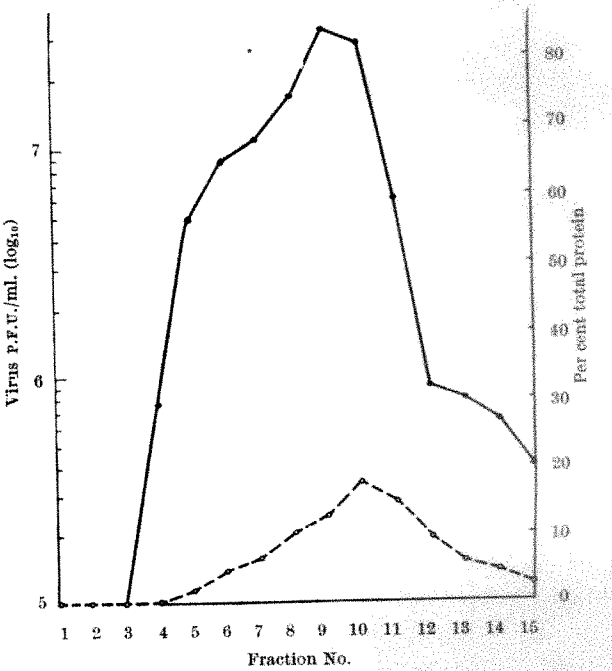

Fig. 1. Poliovirus (—) and protein contents of eluate (———) obtained with 'Cellex-*E*' columns

* Present address: Co-Carcinogen Group, Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

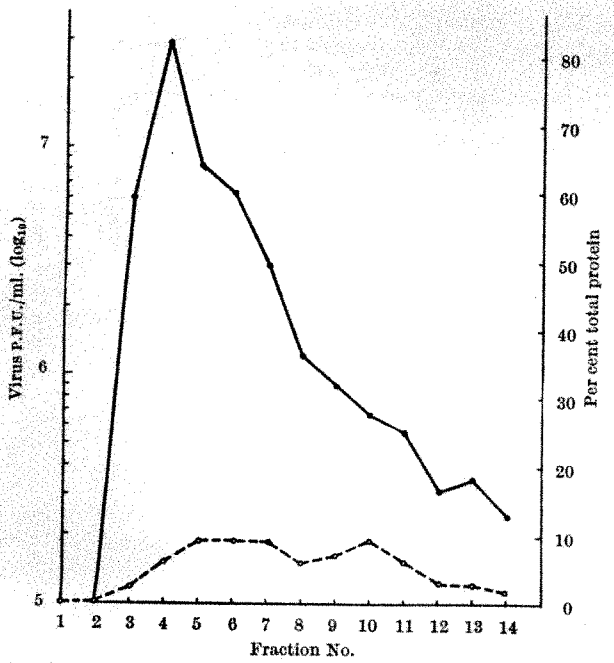

Fig. 2. Poliovirus (—) and protein contents of eluate (- - - -) obtained with 'Sephadex *G*-25' columns

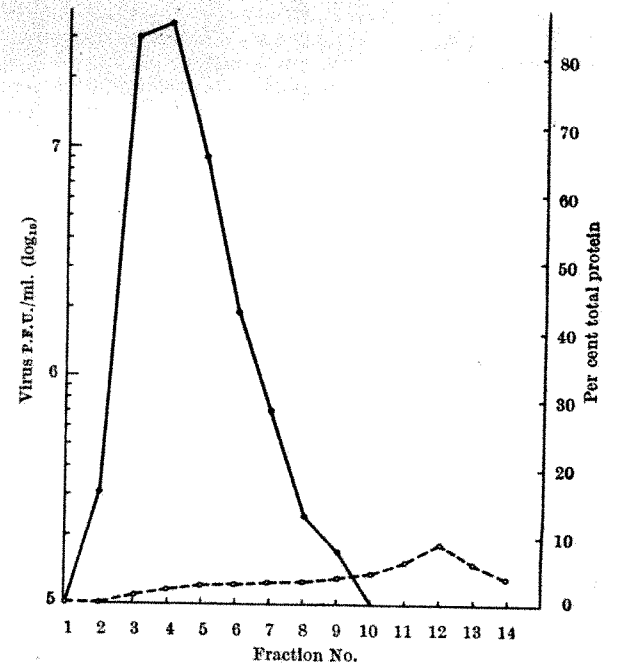

Fig. 3. Poliovirus (—) and protein contents of eluate (- - - -) obtained with DEAE 'Sephadex *A*-25' columns

column gave an 87·5 per cent protein and a 46·7 per cent viral recovery in a total of 17 ml. of eluate. As seen in Fig. 1, 'Cellex-*E*' resin could not separate extraneous protein and virus adequately. High virus titres were accompanied by relatively high protein content. Similarly, Fig. 2 depicts the efficacy of 'Sephadex *G*-25' columns in separating poliovirus from non-viral protein. It is noted that high virus titres are again associated with high protein content.

DEAE 'Sephadex *A*-25', it is noted in Fig. 3, allows recovery of approximately 30 per cent of the virus prior to appreciable evidence of protein. Once more, when a total of 89 per cent of virus is recovered in the 12 ml. of eluate, only 20 per cent of the total protein in the original lysate is eluted.

When fractions 4, 5 and 6 of the poliovirus preparation from the *A*-25 column were passed again through the DEAE 'Sephadex' column, no further detectable protein was noted though approximately one log of the virus titre was lost in this repassage.

Electron microscopic evidence as seen in Fig. 4 indicates that the viral preparation is quite pure considering that this represents the '*A*-25' eluate 4 and 5 with a titre of 2×10^7 P.F.U. concentrated to 1×10^8 P.F.U. It is evident that this procedure is rapid and efficient in the purification of viral preparations. The poliovirus preparation was originally genetically heterogeneous as indicated by plaque morphology. There was no apparent separation by these resins of genetically heterogeneous polioviruses present in the original crude preparation.

We thank Dr. J. Ghidoni for preparing the electron micrographs.

IMMUNOCHROMATOGRAPHIC PARTITION OF SOLUBLE ANTIGENS ON COLUMNS OF INSOLUBLE DIAZO-GAMMA-GLOBULINS

By Dr. S. DeCARVALHO, A. J. LEWIS, Dr. H. J. RAND and J. R. UHRICK
Laboratory of Cancer Virology and Immunology, Rand Development Corporation, Cleveland, Ohio

ATTEMPTS to render antigens insoluble for absorption of specific antibodies from mixtures have been described[1–7]. The present method represents a reverse approach resulting in insolubilization of antibodies for absorption of specific antigens. Aggregation of whole γ-globulin and of Porter's fraction III by *bis*-diazotized benzidine (BDB) with conservation of C'F, HA and skin-sensitizing antibody properties is described by Ishizaka[7a,b].

During attempts to couple cyclic therapeutic compounds to immune γ-globulins[8], it was found that the reaction of bifunctional tetrazobenzidine groups with γ-globulins induced gelation of the protein. This finding was explored with the view of the utilization of the three-dimensional polyglobulin as an insoluble absorbent for specific antigens.

Preparation of Polyglobulin Column. (1) Diazotization of the benzidine was accomplished as described before[8]. (2) Copolymerization of immune γ-globulin: in a 1,000-ml. beaker place 600 ml. of a solution of 1·6 per cent γ-globulin in 1/15 M Sørensen phosphate buffered saline *p*H 7·2 (PBS 7·2). This solution is kept to 8° C during the operations. In a period of 30 min add 720·0 mg of the tetrazobenzidine with slow stirring to avoid foaming. Wait 7 min and then add 10 ml. of 8 N potassium carbonate. Continue to stir for another 10 min. Stirring during coupling prevents massive gelation of the globulin. The final product has the following probable composition:

The mixture is then filtered in a Buchner and washed with PBS 7·2. The slurry is resuspended in 60 ml. of PBS 7.2. It consisted of particles of uniform size (0·5 mm) with a rubbery consistency which on microscopic examination revealed arrangement in bundles of anastomotic fibres with crystalline features under polarized light. The resuspended slurry is placed in the column all at once and allowed to pack by gravity. The antigen solution is added to the packed columns and allowed to soak the column thoroughly. The flow is then stopped and the column containing the soaked antigen is incubated for 1 h at 4° C. After this time, the stopcock is turned and the collection of the adsorbate started. The flow rate in this column averages 120 drops/min at the point of collection. The column and vessel in which the absorbate is collected are surrounded by a polyethylene bag containing crushed ice to maintain the temperature of the column and the absorbate at 4° C. The following antigen–antibody systems were tested on these columns.

System I: Mixtures of protein antigens from pooled human tumours through columns of equine anti-normal human γ-globulin.

System II: Mixtures of protein antigens from pooled human leukæmic tissues through columns of equine anti-normal human γ-globulin.

System III: A mixture of tetanus toxoid fluid and rabbit serum through columns of equine anti-tetanus immune γ-globulin (tetanus antitoxin, TAT).

Results in Systems I and II. A column of equine anti-normal human γ-globulin (Lot $NH_{2,4}$ *GG21*)[9] was prepared by placing 9·6 g of polyglobulin in a 30 cm × 1·25 cm glass column in 50 ml. of PBS 7·2 at 4° C. To the packed column, 50 ml. containing 4·3 g of pooled leukæmia protein, Lot *LK26B*[9] in 1/10 M glycine buffered saline, *p*H 10·4 (GBS 10·4), were added. Absorbate 1 was sampled and re-run twice more, giving absorbates 2 and 3. After this, 50 ml. aliquots of PBS 7·2 were added and washings 1–16 obtained (Table 1).

Table 1. Precipitin Titres in a Two-dimensional Titration System

Fraction	Reaction against: Equine anti-human normal γ-globulin	Equine anti-leukæmia γ-globulin	Rabbit anti-horse γ-globulin
Pooled normal protein	2^{-7}	2^{-2}	0
Pooled leukæmia protein *LK26B*	2^{-3}	2^{-5}	0
Absorbate 1 of *LK26B*	2^{-1}	2^{-4}	0
Absorbate 2 of *LK26B*	0	2^{-5}	0
Absorbate 3 of *LK26B*	0	2^{-6}	0
First washing	0	2^{-4}	0
Sixth washing	2^{-3}	0	0
Sixteenth washing	0	0	0

The different fractions were tested by the precipitin methods described before, namely, single and double gel-diffusion. Single gel-diffusion is performed either as serial dilutions of antibody versus constant antigen concentration[10], here referred to as single unidimensional gel-diffusion, or a checkerboard titration of dilutions of the antigen versus dilutions of the antibody[11], here referred to as single two-dimensional gel-diffusion, or the double gel-diffusion method of Ouchterlony as modified by Korngold[12]. A similar column in the same conditions was tested with pooled tumour protein, Lot *TU25A*[9]. The results are shown in Table 2 and Fig. 1.

Results in System III. Reagents: (*a*) Tetanus toxoid (Lilly) containing 15 L_f units of tetanus toxoid/ml. (*b*) Rabbit serum (Microbiological Associates, Lot No. 1294)

Table 2. Precipitin Titres in a Two-dimensional Titration System

Fraction	Reaction against: Equine anti-normal human γ-globulin	Equine anti-tumour γ-globulin
Pooled normal protein	2^{-7}	2^{-3}
Pooled tumour protein *TU25A*	2^{-3}	2^{-1}
Absorbate 1 of *TU25A*	2^{-1}	2^{-3}
Absorbate 2 of *TU25A*	0	2^{-4}
Absorbate 3 of *TU25A*	0	2^{-4}
First washing	0	2^{-4}
Sixth washing	2^{-3}	0
Sixteenth washing	0	0

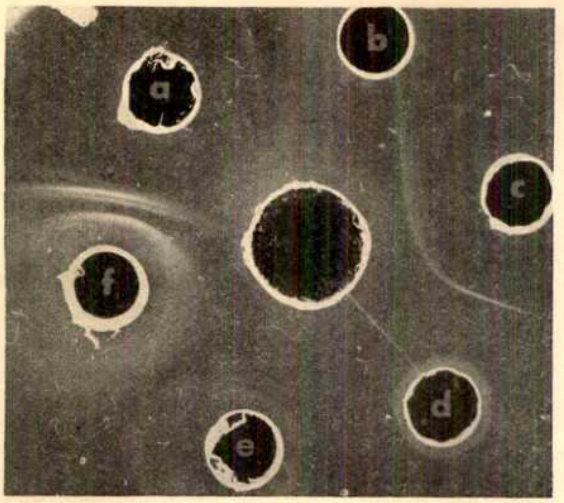

Fig. 1. Double gel-diffusion plate showing results in experimental System I. In the centre and in *e* absorbate 3 from a tumour protein mixture absorbed on a column of polymerized equine anti-normal human γ-globulin. In *a*, the anti-normal horse γ-globulin used in the column showing no reaction against the absorbate of tumour proteins but reacting against *b*, a rabbit anti-horse γ-globulin which does not react with the tumour absorbate. In *c*, equine anti-tumour γ-globulin showing reaction of identity against the unabsorbed (*d*) and the absorbed tumour proteins (centre and *e*). An additional antigen appears in the absorbed material. In *f*, pooled human γ-globulin showing strong reaction against anti-normal equine γ-globulin (*a*) but none against absorbed tumour proteins (centre and *e*)

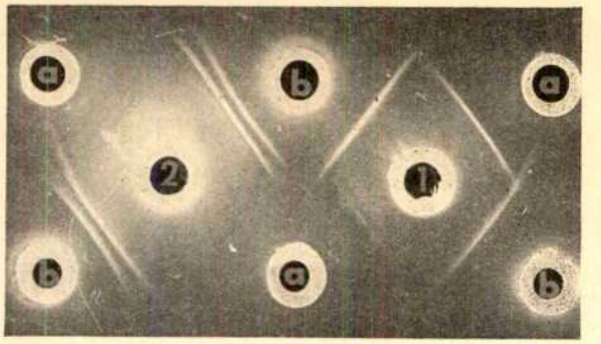

Fig. 2. Double gel-diffusion plate showing results in System II. In *a*, tetanus antitoxin (TAT). In *b*, sheep anti-rabbit γ-globulin. In 1, mixture of tetanus toxoid rabbit serum reacting as expected with the corresponding antibodies which are otherwise unidentical. In 2, absorbate of the antigenic mixture through a column of poly-TAT showing disappearance of the tetanus toxoid and persistence, with further antigenic enrichment, of rabbit serum

containing 4·6 g protein/100 ml. (*c*) Equine tetanus antitoxin, TAT (Lilly, Lot No. 080–823880), as a globulin concentrate containing 3,000 neutralizing units and 0·22 mg protein/ml. This corresponded to a precipitin titre of 2^{-9} against the tetanus toxoid. (*d*) Sheep anti-rabbit-serum globulin (Colorado Serum Co., *CS* 1466). A sheep immune globulin with a precipitin titre of 2^{-3} against pooled rabbit γ-globulin.

A column of 1 cm × 0·5 cm was made with 13 mg of poly-TAT. Preliminary determination of the precipitin titre and zone of equivalence of the TAT toxoid system provided the estimation of the amount of toxoid not in excess of the total precipitating capacity of all the TAT in the column. Accordingly, 0·3 ml. of toxoid was diluted in 0·6 ml. of rabbit serum and the mixture brought to 10 ml. volume with PBS 7·2. The mixed antigen dilution was then run twice through the column and samples of the absorbates tested in precipitin systems. Table 3 gives the results and Fig. 2 shows the disappearance of tetanus toxoid from its mixture with rabbit serum after absorption through a column of diazo-antitoxin.

The results of the foregoing test seem to indicate that:

(1) The polymerized equine γ-globulin is totally insoluble since no traces were detected in absorbates or washings by reaction with a high-titred rabbit anti-horse γ-globulin.

(2) The polyglobulin possesses full and specific antibody activity since it retains all normal antigens from the pooled tumour protein after two absorptions without retaining all the anti-tumour activity as tested by reaction of the absorbates against an equine immune γ-globulin possessing both anti-normal and anti-tumour activity.

(3) There is no non-specific adsorption of non-specific antigens as shown by the fact that leukæmia or tumour antigens react to higher titres after absorption through the column than before in their mixture with normal antigens. The absorption which seems to occur in the column has the characteristics of an immune reaction. As in any other precipitin reactions in gels of soluble antigens and antibodies, an excess of antigen prevented absorption in the column.

Thus, when three times the amount of antigen in the zone of equivalence predicted was added to the column, no absorption of antigens was detected. Instead, quantitatively, mg/mg, they were all recovered in the absorbates and washings. It is indispensable to conduct pilot tests of the system under examination by single two-dimensional diffusion (checkerboard titration of dilutions of the antigen versus dilutions of the antibody), to find the ranges of the zone of equivalence, and thus to avoid a pro-zonal system in which no absorption would take place in the column since a large excess of antigen will dissociate antigen already bound. This may be the reason why even in well-known systems of predetermined conditions complete absorption might not occur before the second or third run through the column.

(4) Washing the columns after absorption with a buffer of composition, molarity and *p*H different from the buffer used as solvent for the antigen results in: (*a*) dissociation of the specifically absorbed antigens; (*b*) recovery of a clean column that can be re-used for absorption of further material. The column used to absorb an aliquot of tumour antigens was re-used four times to absorb three more aliquots of the same pooled tumour antigen, yielding all four times the same results in terms of precipitin titres.

Tight packing in the lower segments of the columns may end up greatly reducing the flow rate. Inverted flow and recycling principles such as proposed by Porath may obviate this problem. The use of tyrosine to stop the polymerization process and grade the particle is also under study.

Further work is under way to demonstrate the 'cleanliness' of antigens absorbed by polyglobulins, including immunization of animals and other immunochemical analyses.

Table 3. Precipitin Titres in a Two-dimensional Precipitation System

Fraction	Reaction against: Sheep anti-rabbit γ-globulin	TAT	Rabbit anti-horse γ-globulin
Mixture of tetanus toxoid and rabbit serum	2^{-3}	2^{-9}	0
Absorbate 1	2^{-3}	2^{-7}	0
Absorbate 2	2^{-3}	0	0
First washing	2^{-3}	0	0
Third washing with PBS *p*H 7·2	2	2^{-3}	0
Sixteenth washing	0	0	0

'UNREWARDED' EXPLORATION AND LEARNING OF COMPLEX MAZES BY WILD AND DOMESTIC MICE

By Prof. D. H. BRANT* and Prof. J. LEE KAVANAU
Department of Zoology, University of California at Los Angeles

DOMESTIC rodents tested for brief periods in simple mazes in the absence of extrinsic rewards may show 'latent learning', but their maze running performance fails to improve[1]. The limitations imposed by the experimental design of such investigations have not always been recognized[2,3], leading to an over-emphasis of the role of extrinsic rewards in general theories of learning. This article describes the learning of highly complex mazes by wild and domestic mice in the absence of extrinsic rewards (that is, 'unrewarded').

Mazes[3] were constructed as follows: The *TGPS* maze consisted of passageways made of glass tubes (80 ft. long), plastic strips (30 ft.), and aluminium partitions fastened to a plywood board mounted at a 45° angle (112 ft.). The vertical transparent maze (*VT*) consisted of aluminium partitions fastened between upright layers of acetate film (245 ft.). The vertical dark maze (*VD*) was similar to the *VT* maze, but plywood replaced the acetate film (224 ft.). All passageways were 1·5 in. wide. Each maze contained approximately 2,000 1·5 in. cubic units of space. The average parameters (one way) for the mazes were: shortest path, 96 ft.; required climbs, 20 ft.; 90° turns, 313; blind alleys, 148 (58 per cent of the total space).

Equal access was provided to the mazes via empty cages and connecting passageways. In addition, the mazes were connected to a series of cages containing food and water, dirt, an activity wheel, and a nest[3]. Gross movements were recorded automatically by electromagnetic counters and an event recorder that were triggered as an animal passed under each of 20 hanging gates placed along the shortest routes. Visual monitoring by television in the deep red and infra-red supplemented these records[3].

In complexity and extensiveness the maze systems were roughly intermediate between conventional laboratory mazes and the habitat of a wild mouse. Accordingly, it was anticipated that exploration and learning of them might lead to the establishment of movement patterns similar to those observed in the field[4]. To test this hypothesis, mice of different environmental and genetic histories were examined. They are referred to by a hyphenated pair of capital letters; the first letter designates their environmental background and the second their genetic background, as follows: (1) 6 *L-W* (laboratory-wild) canyon mice, *Peromyscus crinitus stephensi*, that is, wild animals kept for long periods of time in the laboratory (including F_1 and F_2 generations); (2) 6 *L-W* deer-mice, *P. maniculatus sonoriensis*; (3) A *W-W* (wild-wild) group including 2 *P. c. stephensi*, 2 *P. m. gambelii*, and 3 *P. m. clementis*, that is, freshly captured animals; (4) 1 *W-W* and 3 *L-D* (laboratory-domestic, Swiss strain) *Mus musculus*.

The nest cage of each mouse was connected to the enclosure for 4–12 days (average 7·5). The activity wheel was unlocked for 2–5 days (average 3·3) during this period. Groups were used approximately in the order listed except that *W-W Peromyscus* were used as they became available.

Of the 23 mice, 12 completely explored only one maze (11 *TGPS*, 1 *VT*), 7 completely explored both the *TGPS* and *VT* mazes, while 2 completely explored all three mazes. Once an animal began exploring a maze it usually completed the exploration on the same day and did not explore another maze for several days, resulting in step-like increases in exploration (Fig. 1). In some cases mice failed to return to explored regions, much as wild animals appear to abandon portions of their habitat[4].

The three mice that failed to explore more than a small portion of any maze (2 *L-D Mus* and 1 *W-W P. m. clementis*) evidenced what might be described as highly fearful behaviour. Such behaviour also appeared to be responsible for the low level of exploration found to be typical of all *W-W Peromyscus*, a characteristic which led to the nearly uniform results from this genetically diverse group, as shown in Fig. 1*C*. Apparently low activity-levels reduce exploration, whether they are a product of domestication or are due to fear or conservativeness. Only 7 mice (4 *W-W* and 3 *L-W*) were away from food and water long enough (24 h) to be considered lost. Three of these, the *W-W Mus* and 2 *W-W Peromyscus*, were returned to the food and water cage after being lost for 33–48 h; the remainder found their way back.

All the *L-W* mice explored at least one maze (Fig. 1*A* and 1*B*). Comparisons between species, sexes, parental and filial generations, etc., were complicated by the fact that successive inhabitants tended to explore more extensively, apparently because of the accumulation

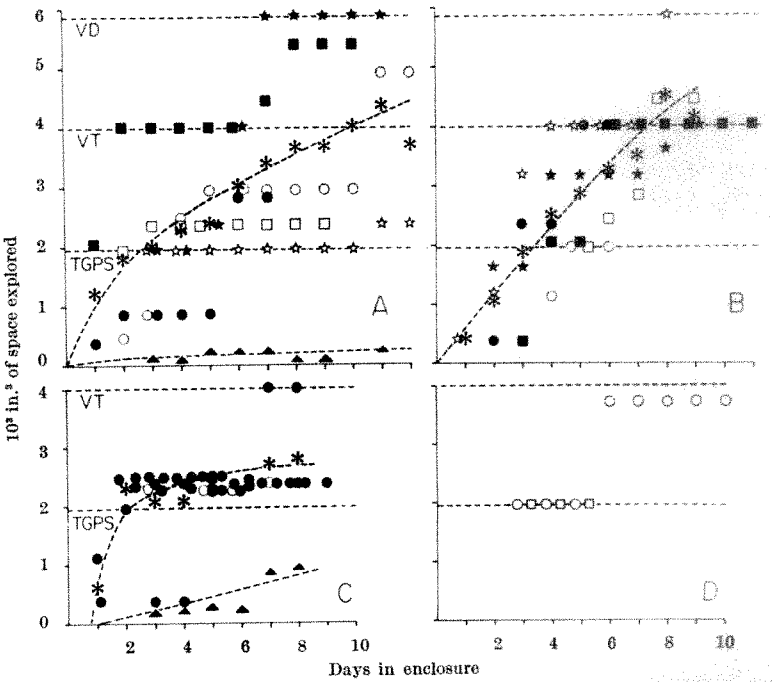

Fig. 1. Exploration of the *TGPS*, *VT*, and *VD* mazes by: (*A*) 6 *L-W P. crinitus*; (*B*) 6 *L-W P. maniculatus*; (*C*) 6 *W-W Peromyscus* of both species; (*D*) a *W-W* (circles) and *L-D* (squares) *M. musculus*. Open symbols represent females and closed symbols males. Individual males are not identified in *C* because of the uniformity of their behaviour. Asterisks, average values of space explored; solid triangles, average values of space 'abandoned'. The number of 1·5 in. cubical units of space in each of the mazes is indicated by the distances between the horizontal lines. Not shown in appropriate sequence is the fact that 4 animals explored *VT* before *TGPS*

* On leave from Humboldt State College, Arcata, California.

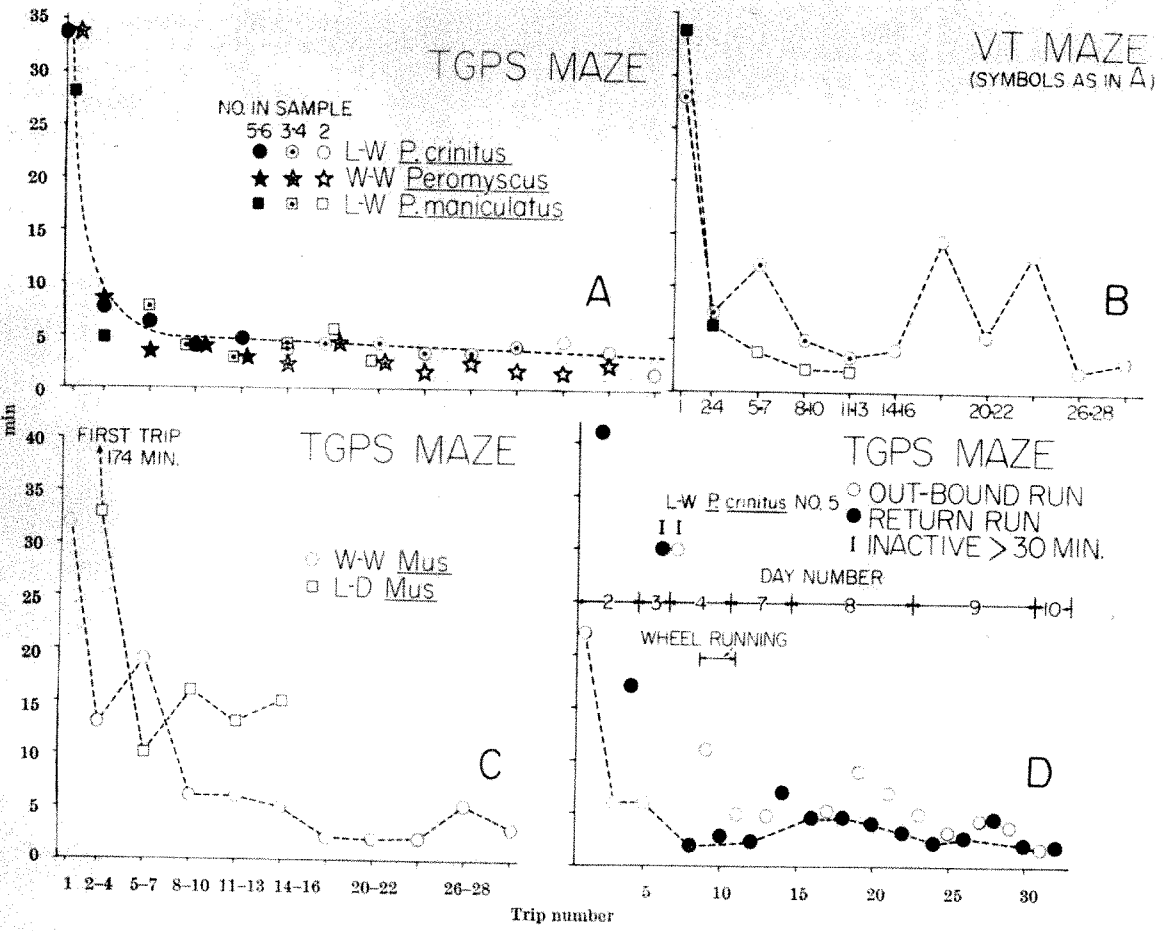

Fig. 2. Time to complete one-way trips through the *TGPS* and *VT* mazes. The average durations of the first trip and of the fastest of each succeeding triad of trips are plotted. The curve in *A* gives the times for the *L-W P. crinitus* (circles); the curves for *L-W P. maniculatus* (squares) and *W-W Peromyscus* (stars) are not plotted but are very similar. One *W-W Peromyscus* also ran the *VT* maze; its times are not shown but they lie roughly between the values for the other two groups in *B*. In *D* the durations of all trips through the *TGPS* maze are recorded for a representative *P. crinitus* (solid circles in Fig. 1*A*). The values for the fastest trip in each triad are connected by the straight broken lines. Note that this *P. crinitus* made only two trips in the maze during the period when the activity wheel was unlocked (days 4–6)

of excreta and other odoriferous substances. Accordingly, the curves of exploration for the 12 *L-W Peromyscus* (Fig. 1*A* and 1*B*) do not necessarily reflect species differences, although the sex differences may be significant.

The first round trip through a maze was completed after an average of 2·8, 4·4, and 2·6 days in the enclosure by 6 *L-W P. crinitus*, 6 *L-W P. maniculatus*, and 7 *W-W Peromyscus*, respectively. The corresponding averages for the amount of active time spent in a maze before reaching its end for the first time were 325, 297, and 239 min, respectively. The proportions of the latter times spent in previously unexplored sections of the maze were 22, 39, and 77 per cent. These figures reflect the fact that the *W-W Peromyscus* tended to explore a maze completely during a single sustained period, whereas the *L-W Peromyscus* usually left a maze and returned to it several times before completely exploring it. Only one *L-D Mus* and the *W-W Mus* did any exploring (Fig. 1*D*).

Confining an animal in a maze greatly reduced the time required for complete exploration. Thus, a *L-W* and a *W-W P. crinitus* placed in the far end of the *VD* maze (with food and water) traversed it completely within 220 min, even though both had failed to explore it 'voluntarily' from the other end.

The average duration of the first completed outbound trips for each of the three groups of *Peromyscus* and the one *W-W Mus* ranged between 29·6 and 32·0 min, but the one *L-D Mus* that explored a maze took 171 min. The return trips for both the *L-W Peromyscus* groups not only averaged 36 per cent faster than the outbound trips (7·5 versus 11·4 min) but also were faster than the preceding outbound trips in a significant number of cases (138 out of 210, $P < 1$ per cent). On the other hand, the outbound and return trips of the *W-W Peromyscus* were of about equal duration (7·0 and 6·9 min), with 32 of the 79 return trips being faster than the preceding outbound trips. The one *L-D Mus* that learned a maze and the *W-W Mus* made slower outbound than return trips (42·7 versus 25·1 and 16·0 versus 6·0 min, respectively), and they did so in the great majority of cases (21 out of 27, $P < 1$ per cent). Slower outbound than return trips apparently reflected a tendency to 're-explore' blind alleys on outbound trips. The brevity of these trips (22 min or less for all except the *L-D Mus*), apparently unrelated to a build-up of hunger or thirst, suggests that exploration, learning, and the subsequent running of complex mazes are self-rewarding.

Fig. 2*D* shows the time distribution of successive outbound and return trips in the *TGPS* maze for a representative *L-W Peromyscus*. Note that the time for one-way trips decreased progressively and that the animal spent very little time in the maze when the activity wheel was unlocked. To obtain a measure of the rate of learning, successive one-way trips after the first were divided into groups of three. The times for the fastest trips in each triad are connected by the broken line in Fig. 2*D*.

Since average values for the fastest *Peromyscus* trips (in each triad) through the *TGPS* maze were much the same, only the curve for the *L-W P. crinitus* is given in Fig. 2*A*. The major differences between the mice studied were: (1) *W-W Peromyscus* ran the *TGPS* maze

faster than either of the *L-W* groups (Fig. 2*A*); (2) *L-W P. crinitus* ran more slowly than the *L-W P. maniculatus* in the *VT* maze (Fig. 2*B*); (3) the single *W-W Mus* (Fig. 2*C*) and all *Peromyscus* (Fig. 2*A*) learned to run the *TGPS* maze at about the same rate, whereas the *L-D Mus* learned much more slowly and its fastest trips took about 5 times as long. Notable also was the fact that the running times of *L-W P. crinitus* were more erratic in the *VT* maze than in the *TGPS* maze (Fig. 2*A* and 2*B*); but only two of these animals completely explored the *VT* maze.

The most maze-running during a 24-h period was done by the *L-W P. crinitus* that did not run the wheel. During its 10th day in the enclosure it made 13 round trips (4 *TGPS*, 7 *VT*, and 2 *VD*) totalling 2,370 ft. and including climbs of 610 ft. The inclusion of movements in the remainder of the enclosure and deviations from the shortest pathways would, of course, increase these totals. The mice doubtless would have run the mazes even more had no activity wheel been present and had the periods of observation been longer.

The amount of exploration, learning, running, and climbing which occurred in the enclosure probably would bring a mouse in many wild habitats into contact with all its 'needs' (food, water, mates, etc.). Since these activities persisted even though 'unrewarded', they would appear to be self-rewarding, a finding which casts doubt on the postulate that wide-ranging locomotor movements are motivated by the reduction of hunger, thirst, and sex-drives[3]. Thus, the investigations of learning in simple mazes by domestic animals given extrinsic rewards[1] may have only limited significance for understanding the learning process in wild and relatively unconfined animals.

A NEW HÆMOGLOBIN—$J_{\alpha\ \text{OXFORD}}$ FOUND DURING A SURVEY OF AN ENGLISH POPULATION

By J. LIDDELL and D. BROWN
Department of Clinical Biochemistry, Radcliffe Infirmary, Oxford

R. G. HUNTSMAN
Memorial Hospital, Peterborough

ABNORMAL hæmoglobins are known to exist in purely English families. Two were discovered by chance: hæmoglobin Norfolk, a new variant[1], and hæmoglobin $J_{\text{Baltimore}}$ (ref. 2), already known to exist in the United States[3]. Two were found as a result of a deliberate survey of 1,000 non-related inhabitants of the County of Norfolk[4]. One was the already known hæmoglobin $D_{\beta\ \text{Punjab}}$ (ref. 5), and the other the hitherto not described hæmoglobin $G_{\alpha\ \text{Norfolk}}$ (ref. 4). In a further survey of 1,971 non-related out-patients in Oxford and Peterborough, again one person has now been found to be heterozygous for a not yet described hæmoglobin variant. The family came from Gloucestershire, but there was also some Irish ancestry. In addition to the propositus, a seventy-year-old woman, the variant was found in six of her siblings and one of her two children. No hæmatological abnormality and no morbidity were associated with this hæmoglobin. As it had the electrophoretic properties of hæmoglobin J, and could, on hybridization experiments[6,7], be shown to carry its abnormality in the α-chain, the new variant is named hæmoglobin $J_{\alpha\ \text{Oxford}}$.

The hæmoglobin was isolated[8] and a peptide chromatogram ('finger-print') was prepared[9,10]. Peptide αTpIII was absent. This peptide contains five amino-acid residues of the α-chain, namely, alanyl-alanyl-trytophanyl-glycyl-lysyl, which are in position 12–16 of the 141 residues composing this chain[11,12]. Two new peptides could be demonstrated instead which were in the neutral area and which both contained tryptophan[13]. These findings resemble those described for hæmoglobin $J_{\text{Baltimore}}$ (ref. 14), which differs from hæmoglobin A in its β-chain. In hæmoglobin Baltimore βTpII which in the β^A-chain contains residues 9–17 (seryl-alanyl-valyl-threonyl-alanyl-leucyl-tryptophanyl-glycyl-lysyl) is replaced by two new peptides. One differs only by a replacement of glycyl in position 16 by an aspartyl, and the other is the same peptide, but the following peptide of the β-chain (βTpIII) has not been split off on digestion, because of the partial resistance of the lysyl bond in position 17 to tryptic hydrolysis when it is next to the acidic aspartyl of the β^J-chain.

The position was similar in hæmoglobin J_{Oxford}. One of the two new peptides was isolated by utilizing the fact that the neighbouring peptides in the neutral area contain histidyl, and can therefore be made to move towards the negative pole on electrophoresis at *p*H 3·5, whereas this peptide remains in the neutral area. It could then be finally purified from the remaining peptides in the neutral area by 20-h chromatography[10]. Table 1 shows the results of the amino-acid analysis[15] for $\alpha^A Tp$III and the peptide which can be taken to be $\alpha^J Tp$III. It will be seen that the glycyl of $\alpha^A Tp$III is replaced by an aspartyl in $\alpha^J Tp$III. The formula of hæmoglobin J_{Oxford} is therefore $\alpha_2{}^{15}\text{-Asp}\beta_2$. For the other new tryptophan containing peptide, staining reactions showed that histidine, tyrosine and arginine were also present[13]. The only peptide of hæmoglobin A which contains all three—histidyl, tyrosyl and arginyl—is αTpIV. The additional finding of tryptophan makes it virtually certain that this second new peptide arises from the incomplete tryptic separation of $\alpha^J Tp$III and αTpIV. A proportion of both peptides had failed to separate on tryptic digestion because of resistance to the enzyme arising from the acidic aspartic residue

Table 1. Molar Ratio of Amino-acids formed after Acid Hydrolysis of Tryptic Peptides III from Hæmoglobin A and Hæmoglobin J_{Oxford}

	$\alpha^A Tp$III	$\alpha^J Tp$III
Aspartic acid	<0·1	1·0
Glycine	0·9	<0·1
Alanine	2·0	2·2
Lysine	1·1	0·9
Tryptophan	+	+

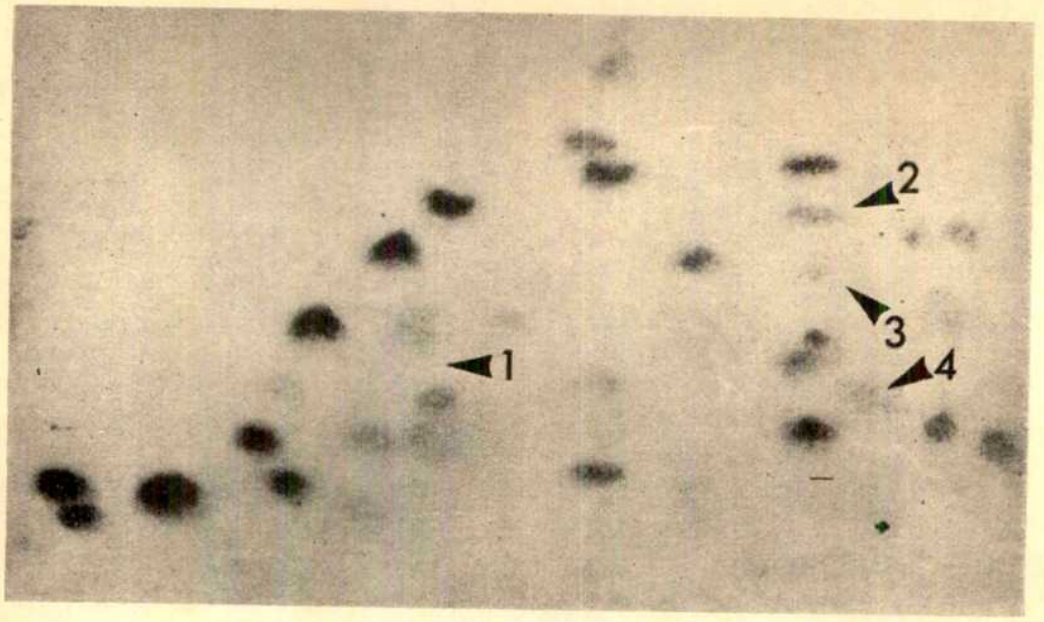

Fig. 1. 'Fingerprint' of hæmoglobin J_{Oxford}. 1 indicates where $\alpha^A Tp$III is missing; 2 is $\alpha^J Tp$III; 3 is $\alpha^J Tp$III—αTpIV; 4 shows the diminished amount of αTpIV

next to lysyl in position 17. This interpretation is further supported by the fact that the peptide corresponding to free αTpIV was much fainter in the finger-print of hæmoglobin J_{Oxford} than in that of hæmoglobin A.

The α- and β-chains of human hæmoglobin A are basically similar[16]. Fig 2 shows that although the amino-acid replacement in the two hæmoglobins $J_{\alpha\ Oxford}$ and $J_{\beta\ Baltimore}$ are comparable, the proportion of the abnormal hæmoglobin is 20 per cent in the first and 50 per cent in the second. One possible explanation is that the coding for glycyl is degenerate and differs for the α- and β-chain. This would result in different messenger RNA for the two aspartyl substitutions. However, it is noteworthy that, as a rule, α-chain abnormal hæmoglobins are present in a lower proportion in the heterozygote than are β-chain variants. It is of interest to be able to compare two hæmoglobins with the same amino-acid substitution in the corresponding position of the α- and the β-chain: $\alpha_2^1{}^5\text{-Asp}\beta_2^A$ and $\alpha_2^A\beta_2^1{}^6\text{-Asp}$ (Table 2). They are identical in their electrophoretic properties, except that the β-variant

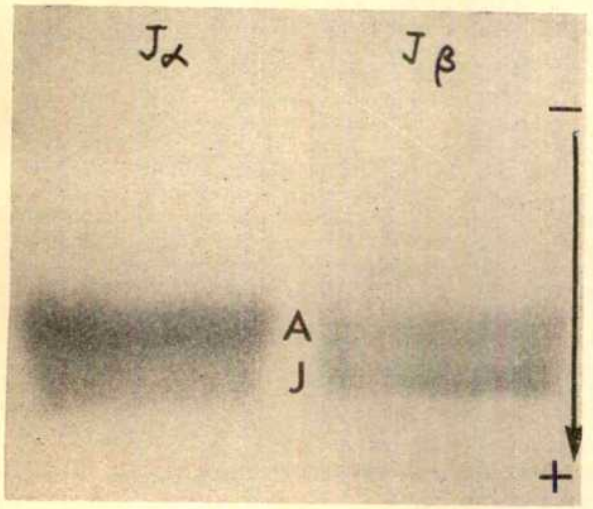

Fig. 2. Paper electrophoresis at pH 8·9 of hæmoglobin A + J_{Oxford} and A + $J_{Baltimore}$. It will be seen that the α-chain variant is present at a much lower proportion in the heterozygote than the β-chain variant

Table 2. The Two Homologous Peptides βTpII and αTpIII
Amino-acid sequences for $\beta^A Tp$II and $\alpha^A Tp$III (ref. 11) and the suggested substitutions for $\beta^J Tp$II (ref. 14) and $\alpha^J Tp$III

βTpII	9	10	11	12	13	14	15	16	17
Hb-A	ser-	ala-	val-	thr-	ala-	leu-	try-	GLY-	lys
Hb-$J_{Baltimore}$	ser-	ala-	val-	thr-	ala-	leu-	try-	ASP-	lys
αTpIII				12	13	14	15	16	
Hb-A				ala-	ala-	try-	GLY-	lys	
Hb-J_{Oxford}				ala-	ala-	try-	ASP-	lys	

just separates from hæmoglobin A at pH 6·5, whereas the α-variant fails to do so. This difference could be shown to be due to the higher proportion of $J_{\beta\ Baltimore}$ in the heterozygote.

The amino-acid substitution in hæmoglobin Norfolk is also a replacement in the α-chain of glycyl by aspartyl, but it occurs in position 57 (ref. 17). The electrophoretic properties of hæmoglobin J_{Oxford} and hæmoglobin Norfolk, however, are clearly different. The present observation is a good example of the importance of the steric position of the amino-acid substitution in the α-chain in determining the physico-chemical properties of the hæmoglobin molecule.

LETTERS TO THE EDITOR

COSMOLOGY

Conservation of Protons in a Stable Nickel Nucleus

THE conservation laws of Nature (for example, charge, energy and baryon number) are considered to be true, since there is no experimental evidence available which proves otherwise. However, there are some theoretical speculations available which consider violations of these conservation laws. Bondi and Gold[1], in their steady-state theory of the cosmos, consider a net production of protons out of 'emptiness', in order to keep the average mass density in an expanding universe constant. Feinberg and Goldhaber[2] remind us that all conservation laws rest only on experimental evidence, and that it is a useful question to search for the limits in which they hold. In this spirit, Backenstoss *et al.*[3] and Giamati and Reines[4] investigated the conservation of baryon number. Alväger *et al.*[5] recently tested the conservation of neutrons in copper nuclei.

Now, it can also be asked : How accurately is it known that in a perfectly closed system the number of protons is constant with time? Obviously it is difficult to perform the experiment with free protons, but protons, assembled in a nucleus, are a rather good 'closed system'. So the question now is : How accurately is the number of protons in a nucleus conserved ? If the number of protons in a nucleus were not conserved, but in fact increased by one, the nucleus would become isotopic with the next heaviest element. Such a process would clearly violate quite a number of conservation laws and would have some consequences for any theory of knowledge.

As an experimental test for the existence of this process, the following hypothetical reaction was studied:

$$^{60}\mathrm{Ni} \xrightarrow{\text{picking up a proton out of the 'emptiness'}} {}^{61}\mathrm{Cu} \qquad (1)$$

The isotope copper-61 is radioactive with a half-life of 3·3 h and decays with emission of positrons. Twenty kg of pure $NiSO_4 + 7H_2O$ were dissolved in 1/10 N HCl, and 1 g $CuSO_4 + 10$ g $Hg(NO_3)_2$ were added. Copper and mercury were recovered from the solution by precipitation with hydrogen sulphide and the copper then separated from the mixed sulphides by heating in an airstream. This yielded CuO, which was placed between two sodium iodide scintillation crystals arranged to detect positron annihilation quanta in coincidence. No activity above the background of about two coincidences per hour was detected in two experiments. Assigning a half-life $t_{1/2}$ for reaction (1), one can state the result with 80 per cent confidence, as follows :

$$t_{1/2}\,[\text{reaction of type (1)}] > 6 \times 10^{18}\ \text{years}$$

Alväger *et al.*[5] give the limit for the destruction of neutrons in a copper nucleus under violation of baryon conservation as $> 10^{21}$ years. They discuss their result in the light of the steady-state theory of Bondi and Gold[1] and assume that the average rate of destruction of neutrons is of the same order of magnitude as the rate of creation of matter (10^{-15} nucleons per cm^3 per year). They further assume that the actual rate of destruction of neutrons, which is investigated, depends only on the number of nucleons present. They calculate then a half-life of a nucleus against destruction of one of its neutrons with 10^{12} years and conclude that the observed stability of nucleons is much greater than 'predicted' by Bondi and Gold[1].

However, it is possible to interpret the limit for the observed stability of a nucleus against spontaneous creation of a proton in such a way as to show that the observed limit for the stability is much smaller than the instability 'predicted' by the steady-state theory. One can assume that the creation of protons is of the same order of magnitude as the creation of the matter and that this creation is only a function of space and that all protons which are created close to the Ni nucleus (10^{-13} cm) are captured by the nickel nucleus. This would give a half-life of the order of 10^{50} years for a reaction of type (1). Therefore, the experimental limit reported in this work is much too low to test the 'creation-of-particle' hypothesis of Bondi and Gold[1]. (However, it is not necessary to assume that in the steady-state theory the creation of matter is only a function of space. Hoyle[6] discussed the possibility that creation might depend on the mass density.)

I thank Drs. A. C. Pappas, G. Rudstam, K. Chackett, T. Alväger and G. Sørensen for their advice and Mr. H. Bersinger for his help.

Olbers' Paradox

OLBERS[1] in 1826 was the first to show that the radiation density everywhere in an infinite static universe should equal the radiation density at the surface of the stars. Hence, Olbers' paradox is that the sky is dark at night.

Let us ignore the absorption of radiation by non-luminous matter. If E_s is the average radiation density at the surface of the stars then the background radiation density in a uniform static universe at time t is :

$$E = E_s\,(1 - e^{-t/\tau_0}) \qquad (1)$$

where $E = 0$ at $t = 0$. In this equation τ_0 is a 'mean collision time' of a photon between emission and absorption by the stars and is :

$$\tau_0 = 4\,V_0/cS \qquad (2)$$

where V_0 is a macroscopic element of volume sufficiently large to contain average conditions and S is the surface area of the stars contained in V_0. If $\rho_0 \sim 10^{-30}$ g cm^{-3} is the present mean density of luminous matter and ρ_s and r_s are the density and radius of a typical star, then $\tau_0 = 4\rho_s r_s/3c\rho_0$. For main sequence stars such as the Sun it follows $\tau_0 \sim 10^{23}$ years. Thus Olbers' conclusion that $E = E_s$ rests on the assumption that the stars have radiated continuously at their present rate for a time of $t > \sim 10^{23}$ years.

Bondi[2] has examined the assumptions underlying Olbers' argument. Of these assumptions the most important for my purpose are : (*a*) the average density of stars and their average luminosity do not vary throughout space and time ; (*b*) the known laws of physics apply. There is an obvious contradiction between these assump-

tions which was not necessarily apparent in pre-relativistic physics. According to the conservation of energy principle stars can radiate at their present rate only for a finite period of time. A static universe may therefore be of infinite age but the radiation life-time of the stars is necessarily finite. Thus if ε is the average luminosity – average mass ratio and t is the time during which the stars have been luminous, then necessarily $\varepsilon t < c^2$. For $\varepsilon \sim 1$ erg g^{-1} s^{-1} it follows $t < \sim 3 \times 10^{13}$ years. Therefore since $t/\tau_0 < \sim 3 \times 10^{-10}$ equation (1) becomes :

$$E = E_s \frac{t}{\tau_0} \tag{3}$$

where $E_s/\tau_0 = \rho_0 \varepsilon$. Hence radiation equilibrium of $E = E_s$ as deduced by Olbers is impossible. The night-sky is dark, or $E \ll E_s$, simply because the stars cannot radiate at their present rate for the immense period of time of 10^{23} years. Thus Olbers' paradox is meaningless; to insist that there is a paradox violates the conservation of energy principle.

The same conclusion follows by arguing in a slightly different way. Let us imagine that the stars are converted entirely into radiation. Then in a static universe the radiation density will be $\rho_0 c^2 \sim 10^{-9}$ erg cm^{-3}. This is roughly the radiation density of moonlight at the Earth's surface and is nothing like $E_s \simeq 10$ erg cm^{-3} at the surface of the Sun. If, more realistically, we imagine only that all hydrogen is converted to iron the radiation density will not affect profoundly the present brightness of the night-sky.

With $\varepsilon \sim 1$ erg g^{-1} s^{-1}, $\rho_0 \sim 10^{-30}$ g cm^{-3}, and using Bondi's[2] estimate of $E = 3\ 10^{-13}$ erg cm^{-3}, it follows from equation (3) that the stars have radiated for a time $t \sim 10^{10}$ years. Thus Olbers' assumptions, with the modification that the stars have radiated for a finite time of the order 10^{10} years, account for the present background radiation density in a reasonably satisfactory manner.

It is generally supposed that the existence of the extragalactic red-shift is a sufficient condition for the resolution of Olbers' paradox and for ensuring a low background radiation-level. I shall show that the existence of a red-shift, or indeed even a blue-shift, plays only a relatively minor part in determining the present radiation level in a variety of non-static models.

I suppose that the universe is divided into a large number of macroscopic elements of proper volume, each having perfectly reflecting walls. In each cell :

$$\mathrm{d}(EV) + p\,\mathrm{d}V = \delta Q \tag{4}$$

where $p = \frac{1}{3} E$ is the radiation pressure and δQ is the incremental gain in energy. In an isotropic and homogeneous universe the radiation conditions within each cell are identical at each instant of cosmic time t. It is therefore possible to dispense with the reflecting walls without in any way disturbing the radiation conditions. We now imagine that during the entire history of the universe a single cell of proper volume V is enclosed with walls which are perfectly reflecting from both inside and outside. At any instant an observer outside V finds that the radiation conditions are exactly the same as those found by an observer inside V. The observer outside V tends to evaluate the radiation density by making a time-retarded integration of the Doppler-shifted contributions from distant stars[3]. The observer inside V, however, tends to use the differential equations of classical thermodynamics for evaluating the density of the radiation emitted by the local stars in a cavity of varying volume. Since both methods must yield identical results I shall adopt the latter method because of its greater simplicity. From equation (4) it follows :

$$\frac{1}{V^{1/3}} \frac{\mathrm{d}}{\mathrm{d}t}(V^{4/3}E) = \frac{1}{4} cS(E_s - E) \tag{5}$$

where the right-hand side is the luminosity of the stars in V minus the rate of absorption of the background radiation by the stars (absorption by non-luminous matter is neglected). This equation can also be derived from the adiabatic relativistic equation using the Robertson line element. Since $V \propto R^3(t)$, where $R(t)$ is a proper unit of length, then :

$$\frac{\mathrm{d}}{\mathrm{d}t}(R^4 E) = \frac{R^4}{\tau}(E_s - E) \tag{6}$$

and $\tau R^{-3} = \tau_0 R_0^{-3}$.

Let us consider the range of models satisfying the relation $R \propto t^n$, where $n > -1$. On integrating equation (6) it is found for $t \gg t_1$, where t_1 is the time of the initial conditions, that

$$E = \frac{E_s}{n+1} \frac{t}{\tau} \tag{7}$$

and $t = nT$ where T_0^{-1} is Hubble's constant. Also $\tau t^{-3n} = \tau_0 t_0^{-3n}$, and the zero suffix denotes the present epoch. The static model is given by $n = 0$, and the steady-state model is given by $n = 1/3$ with $t = \frac{1}{4} T$. For $n > 1/3$ the radiation density diminishes with time and for $n < 1/3$ the radiation density increases. It would be absurd to suppose that the stars can exist when $E \geqslant E_s$ and therefore there is a critical epoch :

$$t_c = \left(\frac{1}{n+1} \frac{t_0^{3n}}{\tau_0}\right)^{\frac{1}{3n-1}} \tag{8}$$

such that for $n > 1/3$ the stars commence radiating at $t_1 > t_c$ and for $n < 1/3$ they cease radiating at $t_2 < t_c$. Some values of t_c are (using $t_0 \sim 10^{10}$ years) : Milne's model ($n = 1$), $t_c \sim 3 \times 10^3$ years ; Einstein–de Sitter model ($n = 2/3$), $t_c \sim 1$ day ; steady state and Dirac models ($n = 1/3$), $t_c = \infty$; static model ($n = 0$), $t_c \sim 10^{23}$ years.

It is seen from equation (7) that the background radiation density is less than the radiation density at the surface of the stars when $t < (n+1)\tau$. At present the background radiation level is low not so much because the universe is non-static but mainly because τ_0 is very large. This feature of our universe is of such overriding importance that the radiation-level is affected only in a comparatively slight way by whether the universe is expanding ($n > 0$) or contracting ($n < 0$). In general, for values of $n > 0$, the sufficient condition for a low radiation-level at present is $t \ll \tau_0$, which is the same as for a static model. This is also a necessary condition because of the conservation of energy principle. Thus the radiation-level is low in our universe at present and the night-sky is dark simply because the stars are so widely separated from each other, or, in other words, because the characteristic time τ_0 is so very large.

RADIO ASTRONOMY

Absorption of Radio Waves in the Galaxy

Observations of the distribution of the galactic radio emission at 4·7 Mc/s for southern declinations[1] have shown evidence of pronounced absorption by interstellar ionized hydrogen within about 20° of the galactic disk. Between declinations −20° and −50° the disk is seen as a dark

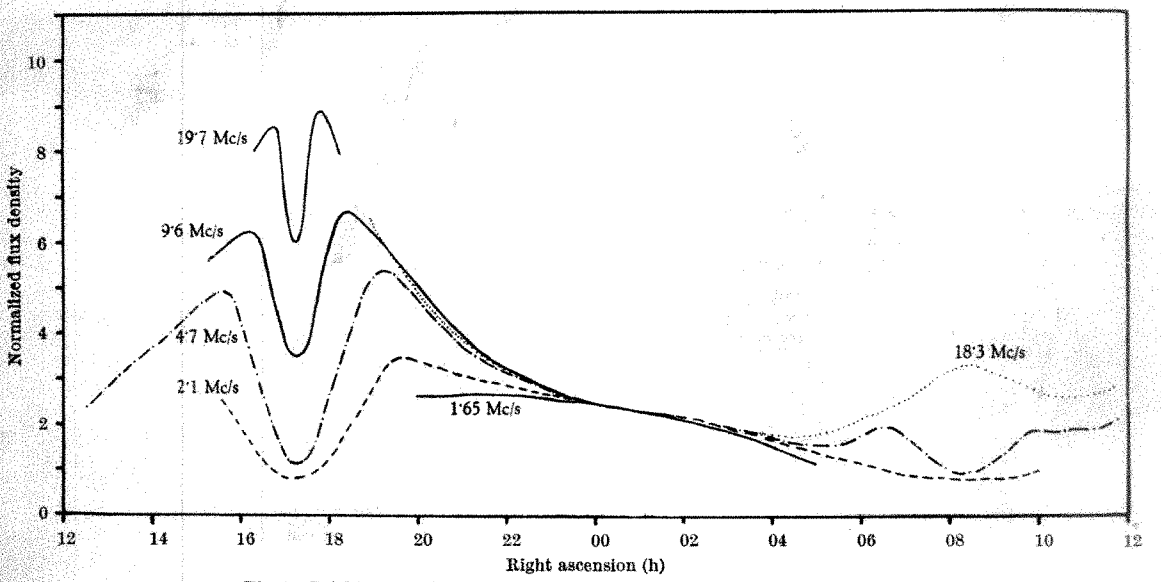

Fig. 1. Brightness profiles of the general background radiation at declination −37°

band approximately one-quarter as bright as the surroundings.

Since the absorption is proportional to e^{-KL}, where $K = 0{\cdot}4N^2T^{-3/2}f^{-2}$, it is a strong function of frequency, where K is of order unity. Observations at other frequencies would be expected to give substantially different brightness distributions and possibly permit the estimation of the absorption coefficient.

Fig. 1 shows a comparison between the 4·7 Mc/s brightness profile in right ascension at declination −37° with profiles obtained in a new series of observations at 1·65 Mc/s and 9·6 Mc/s. The antenna beamwidths were 2° × 5°, 4° × 10° and 32° × 40° at 9·6 Mc/s, 4·7 Mc/s and 1·65 Mc/s respectively. Also shown is a profile at 2·1 Mc/s supplied by G. Reber (private communication) and two from previous observations at 19·7 Mc/s (ref. 2) and 18·3 Mc/s (ref. 4), the beamwidths being 8° × 8°, 1·4° and 17° respectively. These profiles have all been normalized in the direction of greatest galactic latitude (−80°) at 0030 R.A.

The widening of the absorption trough at 1715 R.A. near the galactic centre with decreasing frequency is noteworthy and at the lowest frequency the effect of the absorption can be followed out almost to the galactic pole. The right ascension scan cut through the galactic disk a second time at 0820 R.A. in a direction remote from the centre and again pronounced absorption was observable at 4·7 Mc/s and 2·1 Mc/s, suggesting that the absorbing material exists at much greater distances than the Sun.

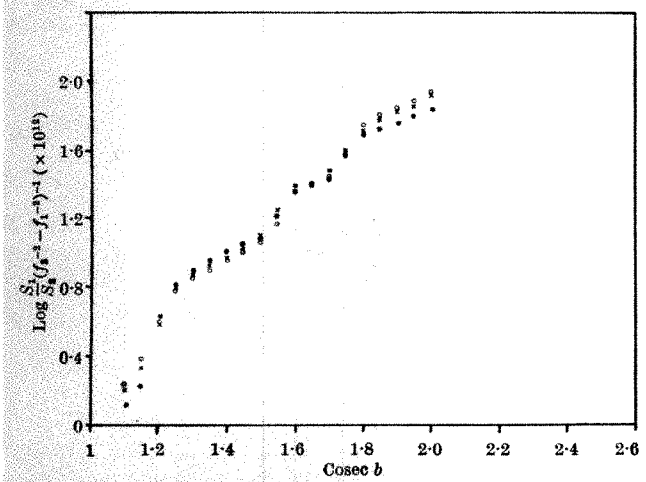

Fig. 2. Variation of normalized brightness ratios with galactic latitude from R.A. 2000 to R.A. 0030 (circles, 4·7/2·1; crosses, 4·7/1·65; dots, 2·1/1·65)

Now providing the ionized hydrogen is distributed uniformly in a parallel layer and substantially all the radiation originates outside the layer, the ratio of the normalized intensities S_1, S_2 at frequencies f_1, f_2 in a specified direction is given by:

$$A = \frac{\log S_1/S_2}{1/f_2^2 - 1/f_1^2} = \frac{0{\cdot}4N^2L_0}{T^3 f_2} (\mathrm{cosec}\, b - 1)$$

where b is the latitude angle, N the electron density, T the electron temperature and L_0 the semi-thickness of the layer. If the foregoing assumptions are correct, a plot of A against b will give a straight line which will be independent of the particular pair of frequencies used. Furthermore, its slope will be a measure of the absorption coefficient K.

In Fig. 2 the value of A is plotted using the profiles of Fig. 1 for the region from 2000 R.A. to 0030 R.A. Between cosec $b = 1$ and cosec $b = 2{\cdot}0$, A is independent of frequency. Deviation of the curves from a straight line indicates that the assumption of uniform density would need modification. However, the deviation is not great and we obtain a mean value for $N^2L/T^{3/2}$ of $6{\cdot}25 \times 10^{12}$ cm^{-5}(°K)$^{-3/2}$ ($b > 60°$). Taking $T = 10^{4\cdot0}K$ and $L_0 = 300$ pc gives $N = 0{\cdot}08$/c.c. This compares with $N = 0{\cdot}1$/c.c. previously obtained from low-resolution spectral intensity observations[3]. However, it should be emphasized that in the present derivation no absolute values of intensity have been used.

For galactic latitudes less than 20° and longitudes in the vicinity of the centre, the foregoing simple disk model does not hold, and A becomes a strong function of frequency in this region. However, the observed profiles may be obtained theoretically if it is assumed that the electron density increases towards the centre and that there is significant disk emission for these directions.

RADIOPHYSICS

An Ion Gyrofrequency Phenomenon observed in Satellites

Barrington and Belrose[1], Gurnett and O'Brien[2] and Brice *et al.*[3] have reported that very-low-frequency emissions at frequencies of a few kc/s may be observed in satellites immediately following an atmospheric which has propagated upwards to the satellite. Brice and Smith[4] suggested that these triggered emissions were related to the lower hybrid resonance for propagation transverse to the Earth's magnetic field.

A related phenomenon has now been observed in the *Alouette I* and *Injun III* very-low-frequency data, examples being given in Figs. 1 and 2 respectively. These noises were first detected, aurally, by one of us (J. K.) on recordings of *Alouette I* made at Stanford. It was realized that the noises were genuine (and not interference from other equipment in the satellite) when similar noises were found at Stanford from tapes of very-low-frequency recordings of the *Injun III* satellite which were on loan from the State University of Iowa.

These noises are observed only after the reception of an atmospheric and are at frequencies much less than 1 kc/s. They show initially a rapid rise in frequency, following which the frequency is very nearly constant. This maximum frequency is 520 c/s in Fig. 1 and 400 c/s in Fig. 2. The satellites were at heights of about 1,000 km (for *Alouette I*) and 1,800 km (for *Injun III*) when the noises of Figs. 1 and 2 respectively were recorded.

It is suggested that these noises may be related to an ion gyrofrequency resonance, since the maximum frequency is approximately the gyrofrequency for protons in the plasma surrounding the satellite.

While the relationship of these noises to the preceding atmospherics suggests a 'triggering' process, it appears possible that the noises are simply dispersed forms of the original atmospheric impulse (with the dispersion arising from propagation from the ground to the satellite).

The work at Stanford was sponsored by the National Aeronautics and Space Administration under grant *NsG*–174–61.

The work at Iowa was supported in part by the Office of Naval Research under contract *N9onr*–93803 and by the

PHYSICS

Extrathermal Electrical Conductivity Measurements in a Magnetoplasmadynamic Generator

A detailed description of the International Research and Development Co., Ltd., magnetoplasmadynamic (MPD) generator has been given previously[1,2]. On July 14, 1964, a series of power generation experiments with cæsium seeding of the helium were undertaken. This series differed from the previously reported runs[3] mainly in the generator and nozzle configuration and materials. To reduce end current leakage, the tantalum nozzle used previously was replaced by a boron nitride nozzle, the exit region of the generator lengthened by 2 in. and the interior of the diffuser inlet spray-coated with alumina. The generator channel was constructed from boron nitride in attempts to reduce the internal current leakage encountered previously with alumina[3]. Sixteen pairs of narrow (1/16 in. × 1/2 in.) tantalum electrodes replaced the five pairs of square (1/2 in. × 1/2 in.) electrodes used previously; the gap between the electrodes was large (3/16 in.), to reduce insulator and boundary layer electrical breakdown. Five pairs of tantalum pins (1/16 in. diam.) were used to monitor open circuit voltages, two pairs in the nozzle and three pairs in the generator exit region. Four static pressure tappings and three thermocouples were also located in the channel wall. During operation of the loop nozzle inlet gas temperatures in excess of 1,700° C were measured. The maximum channel temperature measured was 1,110° C with a corresponding flow velocity of 1,730 m/sec and a Mach number of 0·79.

Fifteen short-duration cæsium injections were carried out at different flow conditions during the loop operation; magnetic fields up to one tesla were used. The cæsium injection circuit gave a nominal seeding rate of 0·2 atomic per cent; this low rate was necessitated by the low capacity of the evaporator. In practice, while cæsium was injected for only a few sec (maximum 15 sec) observed open-circuit voltages lasted much longer and decayed only slowly to zero. In most cases voltages were measured several minutes after seeding had stopped. From these measurements it was concluded that the true seeding fraction was one-half to one-tenth the nominal value.

Open circuit voltages in the channel up to 36 V were generated near the channel inlet, falling to about half this value at exit; Fig. 1 shows values for three runs. The

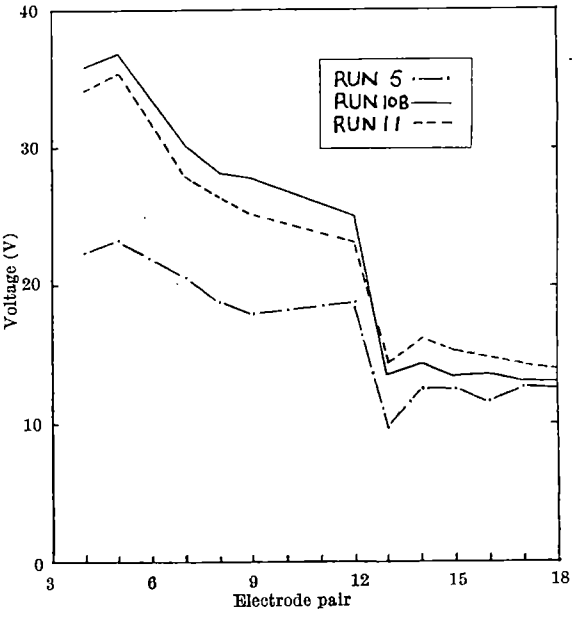

Fig. 1

fall in voltage occurs as gas velocity decreases in the channel; faulty electrical insulation may cause the rapid drop between electrodes 12 and 13.

The electrical conductivity of the plasma was obtained by switching each of the sixteen electrode pairs simultaneously on to five load resistors (18, 68, 280, 1,000 and 4,700 ohms) and open circuit in rapid sequence and displaying the resulting voltage on a 24-channel ultra-violet recorder trace. This sequence takes about a second and can be repeated continuously. From the ultra-violet traces the voltage–current characteristics for the plasma can be constructed. The slope of these characteristics yields the internal resistance (R) of the plasma, which is related to the electrical conductivity (s) by $s = L/RA$, where L is the distance between electrodes (m), A is the electrode area (m^2), S is in mho/m and R in ohms. If the

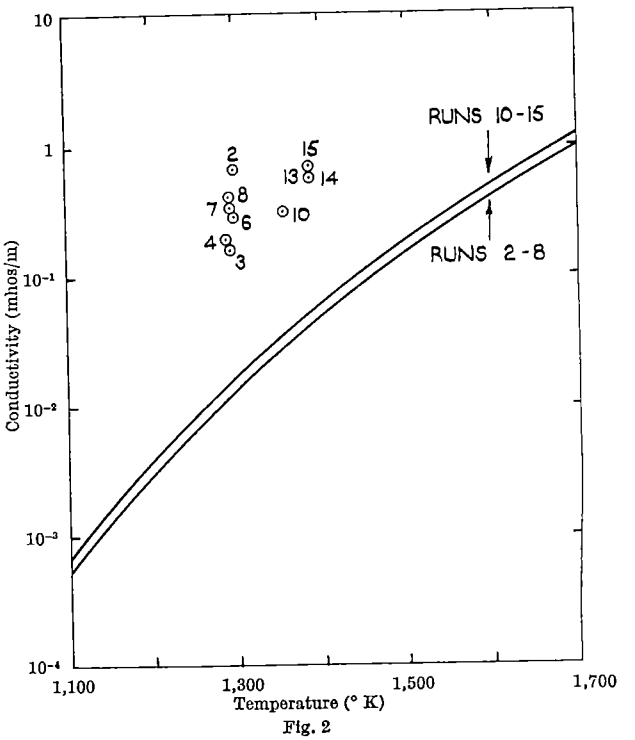

Fig. 2

whole volume of the channel carries current, A is the product of the channel width and the electrode pitch rather than the real electrode area.

Deviations from linearity on the voltage–current characteristics were observed in many cases at high current values; however, the voltage measurements are least precise in these regions: a linear relationship has been used to derive the conductivities quoted here. Fig. 2 shows the average electrical conductivity along the generator channel compared with thermal equilibrium values in the same temperature-range for several runs; a seeding fraction of 0·1 atomic per cent was used in obtaining the equilibrium values and the two curves refer to the appropriate static pressures at channel inlet (the lowest observed in the channel). The observed conductivities are up to fifty times greater than the thermal equilibrium values. Accounting for these values merely by incorrect temperature measurement requires, in the highest cases, errors of more than 300° C temperature measurement. All other factors (seeding fraction, channel pressure, current-carrying area, voltage sheaths near the electrode and internal current leakage) are likely to increase the difference between the observed and equilibrium conductivities. The measurement of such electrical conductivities indicates that some mode of extra-thermal ionization is occurring unless corrections to the observed temperatures are very large. Further experiments using more sophisticated measurement techniques are planned.

During the experiments generated current densities at the electrodes of 750 amp/m² were observed at less than 1,400° K. This is greater than the thermionic current density of tantalum but not that of cæsium; thermionic emission cannot therefore be neglected as an electron-producing mechanism at the electrodes if cæsium deposition occurs.

These experiments were planned and performed by Dr. B. C. Lindley, Mr. R. Brown and members of the International Research and Development Co., Magnetoplasmadynamics team. The work was supported in part by C. A. Parsons and Co., Ltd., and by the U.S. Office of Naval Research under U.S. Navy contract N 62558–4180, and published by permission of the directors of the International Research and Development Co., Ltd.

Generation of Giant Pulses from a Neodymium Laser by a Reversibly Bleachable Absorber

The generation of high-peak power pulses of short duration from a ruby laser by the incorporation of a reversible bleachable absorber into the optical cavity has recently been reported[1]. This communication reports the observation of giant pulses at 1·06μ from a neodymium glass laser using the polymethine dye 3,3′-diethyl-9,11; 15,17-dineopentylene-thia-pentacarbocyanine iodide[2] as the bleachable absorber.

Initially, the dye molecules absorb light due to an allowed singlet–singlet transition at the laser wave-length and laser operation is inhibited. When the gain becomes high enough to overcome this absorption, laser action begins and the dye molecules are rapidly bleached. The cavity Q is suddenly increased and the stored energy is released in a giant pulse.

A 0·25 in. × 2 in. rod of neodymium-doped glass with external dielectric mirrors was used. The threshold for ordinary laser action was approximately 850 joules. A solution of the dye in a rectangular cell was placed in the cavity. The optical density of the dye cell was increased by steps from 0 to 0·3 in a series of experiments. The pulses were measured with a fast rise S-1 planar photodiode calibrated calorimetrically and observed on an oscilloscope having a 4 nsec rise time. The ordinary laser pulses (optical density zero) had a minimum width of about 1 μsec and a maximum amplitude of 12 kW with an input pumping energy of 1,800 joules. As the optical density was increased, the half-width of each pulse, as well as the number of pulses, gradually decreased until a limiting value of 25 nsec (full-width at half maximum) was reached when five pulses occurred. Further increase in optical density, although decreasing the number of pulses obtained, did not lead to an increase in the peak power of each pulse. Giant pulses of 1-MW peak power were obtained. The total energy output of such a giant laser pulse was typically 5 per cent of the total ordinary laser output. No deterioration of the dye due to exposure to the laser light was noted in approximately 100 flashes.

We thank See-Yin Wong for the preparation of the polymethine dye, Dr. W. Buchman for the use of the laser rod and photodiode, and Dr. J. Boyden for the design and construction of the calorimeter.

Absorption Spectra of Silver Vapour

The line spectrum of silver vapour in absorption was first examined by R. G. Loyarte and A. T. Williams[1]. In their work the metal was vaporized in an electric oven of King's type at temperatures between 1,200° and 2,200° C, and the continuous background was furnished by a hydrogen discharge tube. They found altogether 11 lines lying between 3383 Å and 2320 Å, of which two strong ones situated on the long wave-length side of the region, namely, λλ3382·86 and 3280·66, were ascribed to the first doublet of the principal series of silver atom, and nine other weaker lines to ionized atom of the same metal. More recently, J. Ruamps[2], using the same type of oven, observed two band systems of silver in emission, one designated as system A extending from 4900 Å to 5050 Å, and the other as system B from 4100 Å to 4600 Å. Vibrational analysis of the second system led Ruamps to attribute it to silver. As to the more complicated system A, because of the experimental conditions, he was unable to ascertain whether it was due to silver or to other kinds of molecules such as AgN, AgO or AgC. Similar analysis of the bands of system B was afterwards repeated by B. Kleman and S. Lindkvist[3] both in emission and in absorption.

In view of the fact that silver commences to vaporize appreciably at a temperature somewhat lower than its melting-point (960·8° C), and that fused silica tubing can endure a temperature as high as 1,200° C for some time, it was felt to be of interest to investigate the spectral absorption of silver vapour within the workable temperature range of fused silica, so that better controllable experimental conditions could be achieved. The fused silica absorption tube with flat windows at both ends, used in our work, was about 80 cm in length. This tube was connected to a pumping system through which pure inert gas, argon or neon, could be introduced into the tube, in case of necessity. The central part of the absorption tube where a few grams of spectrally pure silver grains were placed could be conveniently heated to any

desired temperature below 1,200° C by means of a temperature-controllable electric furnace. The effective heating length of this furnace was about 40 cm. Spectrograms were taken by a Hilger medium-size quartz spectrograph. The indispensable continuous backgrounds for absorption in the ultra-violet and visible regions were furnished by a powerful hydrogen discharged tube and a tungsten ribbon lamp respectively. The time of exposure for a spectrogram varied from a few seconds to about half an hour, as required by each case.

Attempts to obtain an absorption spectrum of silver vapour with an evacuated absorption tube were unsuccessful. This was because of rapid diffusion resulting in an insufficient accumulation of the vapour in the heated part of the tube. To attain this aim, it was found necessary to introduce a suitable quantity of inert gas, say 30 cm mercury pressure of argon or neon, into the tube. Because of the presence of a foreign gas the effect of diffusion became greatly reduced, and an experiment could be carried on for several hours without the need of replenishing the absorbing material.

Under our experimental conditions, five absorption lines in the ultra-violet region and a system of bands in the visible region have been found. The wave-lengths of the five absorption lines are as follows:

$$\lambda\,\lambda:\ \left.\begin{matrix}3{,}382{\cdot}9\\3{,}280{\cdot}7\end{matrix}\right\}\ \text{doublet},\ 2{,}537{\cdot}0,\ \left.\begin{matrix}2{,}069{\cdot}4\\2{,}061{\cdot}6\end{matrix}\right\}\ \text{doublet}$$

The first two lines and the last two appeared to be doublets, and they have their counterparts in emission as are lines of silver. The first doublet began to turn up at about 700° C, and its intensity increased with rise in temperature. The second doublet, weak in intensity, appeared only at temperatures above 1,000° C. The doublet separations, $\Delta\bar{\nu}$, of the first and the second doublets are 921 cm^{-1} and 183 cm^{-1} respectively. From this it is inferred that these doublets belong to the principal series of lines, $5^2S_{1/2} - 5^2P_{1/2,3/2}$ and $5^2S_{1/2} - 6^2P_{1/2,3/2}$, of the silver atom. The singlet λ2537·0, which was also weak in intensity, showed its presence at about 650° C, but since then its intensity remained practically constant. In consideration of the facts that there is a persistent mercury line of wave-length very close to this line, and that the mercury vapour evolving from a manometer which was attached to the absorption tube might contaminate the silver sample therein by forming a trace of silver amalgam, it is believed that the line in question was due to mercury. Finally, the band system observed was composed of a number of very faint bands extending from about 4100 Å to 4600 Å. Because of their faintness no determination of the wave-lengths of these bands has been made. What can be said about this system is that its locality coincides with that of system *B* of silver. As to the band system *A*, mentioned in the paper of Ruamps, not a trace of it was observable.

It is remarkable that none of the nine absorption lines, identified by Loyarte and Williams as lines belonging to the ionized atom of silver, was observed. From this and the results of our work, and also of others, some conclusions about the nature of silver vapour may be drawn as follows: (1) Monatomic molecules form the predominant part of silver vapour at all temperatures from about 700° C up. (2) At temperatures below 1,200° C no spectrally perceptible amounts of ionic atoms exist in the vapour. (3) Perceptible amounts of diatomic molecules appear at temperatures above 1,000° C.

METEOROLOGY

Polarization and Albedo

Schwerdtfeger[1] has recently directed attention to the mechanism underlying the dependence of short-wave or optical albedo on solar elevation and the presence or absence of cloud cover. He cites as one of the major causes of this dependence the polarization of incident radiation (solar) on reflexion at terrestrial surfaces. The few comments made here are intended to bring out the rather involved interrelation between polarization and albedo, which plays a very prominent part in the solution of radiant-energy transfer problems in the Earth's atmosphere.

A complete description of the ambient radiation field, including the state of polarization, in a plane parallel molecular atmosphere was obtained by Chandrasekhar[2], who assumed the ground to be a Lambertian reflector. The diffusely reflected light from a Lambertian surface is isotropic and natural and is independent of the state of polarization and angle of incidence of incident light. Sekera *et al.*[3] have given quantitative estimates of the radiation emerging from a planetary atmosphere on the basis of the foregoing theory. However, it is quite obvious that naturally occurring terrestrial surfaces exhibit reflective properties which are intermediate between those of a Lambertian reflector and a Fresnel (specular) reflector. The tendency of the reflecting terrestrial surface to behave either like a Lambertian or Fresnel reflector is in turn governed by the roughness parameter as defined by the Rayleigh criterion, which would imply that this tendency is highly dispersive. It also explains the dependence of albedo on solar elevation (angle of illumination).

The foregoing considerations point towards the measurement of spectral reflectance properties (that is, reflecting properties over fairly narrow, well-defined wave-length intervals) as a means of studying the variation of roughness of a given surface over the spectral region of interest. Such measurements would render possible the determination of when a given surface can be considered smooth over a given wave-length region as per the Rayleigh criterion. It would then be possible to determine over what spectral region the polarization features of the incident radiation are changed on reflexion at the given terrestrial surface.

Terrestrial surfaces can be generally considered rough over the visible region with certain notable exceptions—the notable exceptions being vast expanses of water (like calm sea surfaces, lakes) and smooth snow surfaces. Systematic investigations[4] of the dispersion of the angular distances of the neutral points of skylight polarization (the Arago, Babinet and Brewster points) from the Sun or the anti-Sun indicate that this is indeed the case. Theoretical investigations[5] of the ambient radiation field in an atmosphere the lower boundary of which reflects in accordance with the Fresnel formulæ have correctly predicted the disappearance of the neutral points from the Sun's vertical (the meridian through the Sun) for moderate values of elevation of Sun and smaller optical thicknesses (that is, towards the red end of the spectrum) and their reappearance in different meridional planes. Soret[6] has recorded such observations.

The transition of a terrestrial surface from smoothness to roughness (or the other way around) is also governed by the spatial resolution and the geometry of the experimental set-up. When observations of the reflected energy or intensity are made with an instrument with a small field of view very close to the reflecting surface, measured values will be influenced only by the small-scale structural irregularities characteristic of the surface, whereas when observations are made at a great distance from the reflecting surface—especially for grazing angles of illum-

ination—the reflexion process is predominantly governed by the large-scale surface features.

Coulson[7] has made extensive measurements of characteristics of solar radiation reflected by desert soil in the Nevada region. A photoelectric skylight polarimeter[8] was used in these measurements. Relative spectral reflectance values were determined. These measurements indicate that both the polarization and intensity of the reflected solar radiation are strongly dependent on the elevation of the Sun, the altitude and azimuth of the point of observation and the wave-length.

The azimuthal dependence of the intensity of the reflected radiation—especially the marked differences in the intensities of beams reflected in the solar and anti-solar directions—has been correctly attributed by Coulson to the differential amounts of shadow which are seen by the instrument. The spectral reflectance is observed to increase smoothly with increasing wave-length.

Yu Mullama[9] has investigated the problem of light diffusely reflected by a statistically structured surface taking into account the polarization of the incident radiation. He has also presented numerical computations for the specific case of reflexion and refraction at a water surface for two different wind velocities. It is felt that his computations may be extended to the investigation of the polarization and intensity of light reflected by wind-blown sand.

A proper understanding of the interrelation between albedo and polarization, in addition to being of immediate use in the solution of energy exchange problems in our own atmosphere, will play a prominent part in the study of the feasibility of polarimetric studies of surface characteristics of planets with thin atmospheres.

26-Month Oscillation in Atmospheric Properties and the Apparent Solar Diameter

A biennial oscillation in tropical stratospheric winds[1-3] and total amounts of ozone[4-6] has been well documented during the past few years and its discovery has led to a re-examination of much of the earlier work on biennial oscillations in surface temperature, rainfall, tree rings, lake levels and other parameters which depend on conditions in the troposphere[7]. I have argued elsewhere[8] that the oscillation in the stratosphere is caused by changes in the troposphere, and this argument is in line with much of the present thinking about tropospheric–stratospheric interactions, which holds that the lower stratosphere receives its driving energy from below[9-11]. If this reasoning is correct then there must be sought a source for the 26-month oscillation in the tropospheric heat engine. One possibility is some type of internal oscillation; another is that the incoming radiation which drives the tropospheric heat engine (approximately 3000 Å to 2μ) is modulated with a 26-month oscillation.

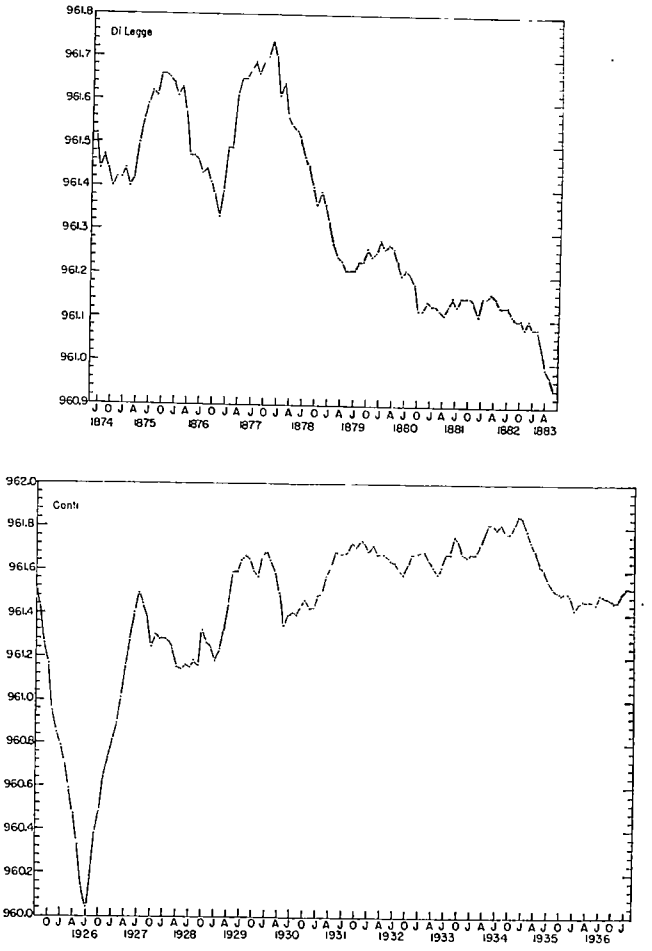

Fig. 1. Twelve-month running means values of solar radius. Units are seconds of arc at the mean Earth–Sun distance

Landsberg, Mitchell, Crutcher and Quinlan[12] have shown that the biennial temperature oscillation in general reverses phase between tropical latitudes and middle latitudes and also sometimes has a phase variation with longitude in middle latitudes. Such complex behaviour is not inconsistent with an extra-terrestrial modulation. An increase in the heat energy to be transported polewards in the troposphere may lead to an increase in the amplitude of the large-scale standing eddy flow patterns in the troposphere; this in turn would mean increased upward velocities at some middle latitude stations with concomitant cloudiness and lower temperatures. It has been shown elsewhere that the amplitude of these standing eddies in the troposphere has a direct effect on the ozone amounts in the stratosphere[13].

One possible source of such extra-terrestrial modulation of the incoming radiation is a periodic change in the solar diameter. It seems to me that this possibility has not been eliminated in spite of an enormous amount of observational work. Airy[14], Cullen[15], Lane Poor[16], Schur and Ambronn[17], and Di Legge[18], to name a few, have examined this question with a variety of observational techniques, and the present-day reader of these early papers cannot help concluding that the question of variability is unresolved. It is noteworthy that Abetti in his treatise on the Sun[19] is also of this opinion. Much of the material reported has been compounded into annual mean values which are not useful for the present purpose. The Italian astronomers have made a comprehensive investigation of the problem from observations collected between 1870 and 1940 and many of these have been published either directly or as monthly means and corrected to a mean Earth–Sun distance.

From two such series of these observations[18,20], each taken by a single observer, twelve-month running means have been calculated and are plotted in Fig. 1. The observations by Di Legge suggest the presence of a biennial oscillation in the apparent solar diameter. It is difficult to establish whether this is a real variation or whether the periodicity was introduced through the refractive correction based on tropospheric temperatures; in fact, there is some phase correspondence between the oscillation in Fig. 1 and the biennial temperature oscillation at Uppsala reported by Landsberg *et al.*[12]. The diameter data taken by Conti also show some evidence of the fluctuation. Undoubtedly a personal element is involved in these observations and values by different observers do not agree exactly. Such features as the large minimum in 1926 in Conti's curve are shown by other observers; these may be related to atmospheric opacity and aerosol content.

If radius changes of about 0·3 sec of arc, as evident in Fig. 1, did actually occur they would change the resulting radiation at the Earth by about 5 parts in 10,000, which is well below the sensitivity limit of present radiation instrumentation. An order of magnitude estimate shows that a similar change in input radiation could be produced if sunspots with a temperature of 4,800° K covered about 1/1,000 of the solar disk. A considerable amount of effort has been spent on the possible relationships between sunspot effects and the atmospheric circulation, and if the solar diameter observations represent a real variation it would seem desirable to examine the effects of diameter changes in more detail.

It may be argued that the Sun is not a cool star of the type normally associated with long-period variables. May not this be simply a reflexion of the fact that variables with such small amplitude cannot normally be detected? One purpose of this communication is to raise again the question of Armellini[21]: "Il sole è uua stella pulsante?", and to suggest that a further investigation with modern instrumentation might be appropriate. I shall be grateful for any daily or monthly values of diameter that might be available from regions outside Europe since it seems that data from a series of locations would allow one to unravel the effect of atmospheric refraction and temperature changes in the results.

This communication comments on one possible source of the oscillation which seems to warrant further examination. It is intended to discuss others in a separate communication.

GEOLOGY

Pleochroism of Orthopyroxenes

DR. M. S. MURTY has recently concluded[1] on the basis of two analysed minerals that the strength of the pleochroism of orthopyroxenes of the charnockite series can be correlated with their titanium content, it having been noted earlier[2] that the pleochroism is independent of the iron content of these minerals. More recently, however, it was suggested[3] that the pleochroism of orthopyroxenes can be correlated with their alumina content and with the resultant contraction of their cell parameters, that is, it may be largely a physical effect.

Inspection of a semi-quantitative record of the intensity of pleochroism in 12 analysed orthopyroxenes of the charnockite series[2] does not support Murty's conclusion that the intensity of pleochroism can be correlated with the titanium content: indeed, the most pleochroic minerals have the lowest titanium contents but do contain more than 4 per cent alumina. Further examples can be taken from a compilation of 47 orthopyroxene analyses[3]; for example, specimens 186b/54 and 177/54, both from British Guiana, have roughly equal amounts of titania at 0·17 and 0·19 per cent respectively; their alumina contents, however, are 1·37 and 9·48 per cent and the latter mineral is very much more pleochroic.

In an examination of Scottish orthopyroxenes[4], two bronzites are shown to have roughly equal amounts of alumina, with 4·53 and 4·45 per cent, and are equally strongly pleochroic, but the first has twice the titania content, with 0·19 and 0·09 per cent respectively. Thus, on further inspection, Murty's data for two pyroxenes with titania 0·45 and 1·05 per cent, and alumina 2·83 and 4·06 per cent, the second pyroxene being more strongly pleochroic, could be taken to support my contention that the strength of pleochroism of orthopyroxenes can be correlated with their alumina content.

R. A. HOWIE

Department of Geology,
King's College,
London, W.C.2.

[1] Murty, M. S., *Nature*, **202**, 283 (1964).

[4] Howie, R. A., *Min. Mag.*, **33**, 903 (1964).

IT has been noted by several investigators that the magnesium-rich orthopyroxenes are more strongly pleochrotic than the iron-rich members, indicating that the strength of the pleochroism is not dependent on the iron content. Kuno[1] observed no relationship between the strength of the pleochroism and the manganese content of the mineral, he having noted no pleochroism in the manganiferous pyroxene, but suggested a possible relationship with the titanium content. In a recent investigation[2], it was suggested that the strong pleochroism may be due to the high titanium content. But Howie (preceding communication) considers that the strength of the pleochroism is independent of the titanium and correlates with the alumina content.

Kuno[1] related the pleochroism in the pyroxenes of the Bushveld type to the exsolution of titanium together with calcium and iron. Howie[3] suggested that it is related to the presence of oriented schiller inclusions. Parras, as quoted by Deer *et al.*[4], considered that the intensity of the pleochroism is dependent on the amount of exsolution of diopsidic pyroxene and ferric iron.

Though oriented schiller inclusions and lamellæ were noted in the orthopyroxenes of the charnockite series, they apparently seem to have no relationship with the strength of the pleochroism as the inclusion free grains are also found to be pleochroic. In the light of the foregoing observations, I am inclined to believe that the strength of

the pleochroism is dependent on the titanium content. The observations of Kuno[1], that the strongest pleochroism occurs in the highest titanium mineral, moderate pleochroism in the low-titanium mineral and no pleochroism in the titanium-free mineral, could be taken to support my contention. Kuno's results do not support the contention of Dr. Howie that the strength of the pleochroism can be correlated to the alumina content, since non-pleochroic pyroxenes 1, 2 and 19 are found to contain 0·93–1·47 per cent alumina. It can be further seen that the strongest pleochroism is in the pyroxene 13 containing 1·70 per cent alumina and the less-intense pleochroism in pyroxene 7 having 2·42 per cent.

Shatter-cone Orientation at Sudbury, Canada

Shatter-coning, a unique type of conical fracturing, appears to be a criterion for shock-induced over-pressures in rock. As such, they have been useful in identifying presumed astroblemes (ancient meteorite impact scars)[1]. So far, about eight shatter-coned structures have been identified around the world[1]. A good analysis of shatter-coning has recently been made by Short[2].

As well as indicating shock deformation at crypto-explosion structures the orientation of shatter cone apexes identifies the arrival direction of the shock waves. In other words, the shatter cones point toward the focus of origin of the shock force, that is, to 'ground zero' in the case of a meteorite impact source. Although in principle it should be possible to locate the direction of ground-zero, it has only rarely been possible to do so. Most shatter-coned structures are small so that shock-fracturing is confined to the central eye. Here the explosion event which immediately follows the shock-fracturing converts the eye of a shatter-coned structure into a nest of megabreccia. Hence the blocks of rock which contain shatter cones are disoriented, making it difficult to relate the orientation of shatter cones found in any particular block to the structure as a whole. The Kentland, Indiana, disturbance provides an exception. In the up-ended strata there, the shatter cones have been shown to be preferentially oriented stratigraphically upward. This suggests that the disturbance is an astrobleme rather than a cryptovolcano[3].

For astroblemes resulting from higher-energy impacts, the peripheral zone of shatter-coning may extend several miles into the country rock. At sites where this zone is spared great disruption and subsequent erosion, an optimum situation for cone-orientation examination should exist. Indeed, this was found to be the case at the Vredefort Ring structure where shatter-coning in the annular ring of upturned strata extends for at least seven miles from the margin of the granite core. Hargraves[4] first demonstrated a remarkable preferred orientation of the cones which has been confirmed by a detailed investigation by Manton[5]. Manton found the shatter cones to point inward toward the centre of the Vredefort Ring and to point upward about 45,000 ft. above the present ground surface. This provides highly suggestive new evidence that this ring structure is an astrobleme as proposed by Boon and Albritton[6], Daly[7] and Dietz[8].

In July 1964 we made a brief examination of shatter-cone orientation at another large shatter-coned structure, the Sudbury structure in Ontario, Canada, long famous for its nickel mines. One of us (R. S. D.) first discovered shatter cones at Sudbury in May 1962. In the summer of 1962 they were also independently found by Hargraves (personal communication) and recognized as similar to those which he had investigated at the Vredefort Ring.

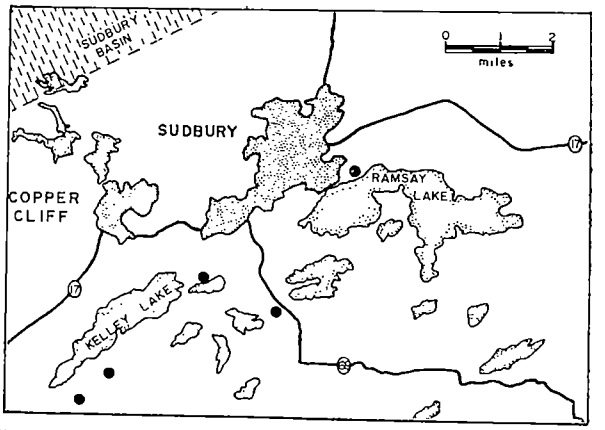

Fig. 1. Southern margin of Sudbury Basin. Solid circles show location of oriented, shatter-coned rock outcrops. Exposures near Kelley Lake are in Mississagi quartzite; outcrop at Ramsay Lake is in Ramsay Lake conglomerate

Fig. 2. Shatter cones in Mississagi quartzite along southern margin of Sudbury Basin structure. Their orientation is such that, when the rocks are returned to their pre-event position, the cones point inward toward the Sudbury Basin. This suggests that the structure is an astrobleme (meteorite impact scar)

In situ shatter-coning at five localities (four in the Mississagi quartzite and one in the Ramsay Lake conglomerate) was sufficiently well developed to allow a preliminary orientation investigation (Fig. 1). An especially fine display of oriented shatter cones is present in a road cut immediately south of the south-western end of Kelley Lake (Fig. 2).

Based on the reasonable assumption that the Mississagi quartzite was an essentially flat-lying formation at the time of the Sudbury event, 1·7 billion years ago[9], the preferential orientation of the shatter cones, on restoration of the beds to horizontal, is toward the centre of the Sudbury basin. The Mississagi quartzite now dips steeply and faces south-south-east. The axes of shatter cones in the Mississagi quartzite (and Ramsay Lake conglomerate) lie preferentially in planes that are essentially parallel to bedding planes. This essentially duplicates the situation at the Vredefort Ring.

Shatter-coning at the Sudbury structure seems to be largely, although not entirely, confined to the well-bedded Mississagi quartzite. The reason for this selectivity is not clear. However, it is empirically known from other

presumed astroblemes that initial compressibility of the rock, fine-grained texture and minimal porosity, and frequent discontinuities (bedding and joint surfaces) in the shock-wave path are conducive to extensive development of shatter cones.

We conclude that the shock force which shattered the collar rocks along the southern periphery of the Sudbury Basin came from the north, that is, from the direction of the Sudbury Basin. This is in accordance with expectations if the Sudbury structure is an astrobleme.

CHEMISTRY

A Simplified Scintillation-counting Technique for assaying $^{14}CO_2$ in a Warburg Flask

AVAILABLE methods for assaying $^{14}CO_2$ in Warburg flasks are of two types. The first[1] involves trapping liberated $^{14}CO_2$ with an organic base, which makes it possible to count efficiently, but at the cost of a rather cumbersome procedure. Trapping with filter paper moistened with sodium hydroxide[2] or potassium hydroxide[3,4] provides a convenient method but with some loss of efficiency. The procedure described here is based on the use of a solvent system described by Belcher[5] that will accommodate up to 3 per cent of a 25 per cent aqueous potassium hydroxide solution with only 3 per cent quenching.

Portions of 0·01 M sodium carbonate containing standardized $Na_2{}^{14}CO_3$ (obtained from the Radiochemical Centre, Amersham) were pipetted into the main compartments of Warburg flasks. Water was then added to bring the total volume to 3 ml. Sulphuric acid (0·2 ml. 6 N) was added from the side arm and the evolved carbon dioxide was trapped in 0·1 ml. 20 per cent aqueous potassium hydroxide contained in the centre well. After shaking for 1 h to ensure complete absorption of the carbon dioxide, the contents of the centre well were transferred with a Pasteur pipette to 5-ml. solvent in a silica counting vial: maximum transfer was ensured by transferring some of the mixture to and fro three or four times. The solvent system consisted of 2,5-diphenyloxazole (PPO) 2 g, 1,4-*bis*-2-(5-phenyloxazolyl) benzene (POPOP) 25 mg, toluene (500 ml.) and methanol (500 ml.). Reagent-grade solvents were used. The solvent system differs from that described by Belcher[5] only in that methanol was used instead of ethanol. The solvent system is very sensitive to oxygen quenching, and oxygen-free nitrogen was therefore bubbled through each vial for 1 min before sealing with a well-fitting cap. Counting was performed in a Nuclear Enterprises liquid scintillation unit at 20° C. Table 1 shows that the recovery of $^{14}CO_2$ radioactivity was independent of the amount of carbonate in the flasks up to 10 μmole. After this, the contents of the centre well cease to be completely soluble in the scintillator solution. The method is thus applicable to volumes of carbon dioxide up to about 200 μl.

Table 1. LIQUID SCINTILLATION COUNTING OF $^{14}CO_2$ RADIOACTIVITY FROM WARBURG FLASKS CONTAINING STANDARD $Na_2{}^{14}CO_3$

Initial radioactivity (d.p.s.)	Carbonate present (μmole)	Count rate (c.p.s.)	Counting efficiency (per cent)
0	0	0·75	—
24·4	2	19·4	76·4
48·8	4	37·4	75·1
73·2	6	55·4	74·7
97·6	8	74·2	75·3
122·0	10	92·0	74·8
146·4	12	102·9	69·8
170·8	14	110·3	64·1

The counting efficiencies were calculated from the count rate obtained after subtraction of the blank value. It can be shown[6] that the radioactivity from ^{40}K in 0·1 ml. 20 per cent potassium hydroxide contributes 0·44 d.p.s. towards the blank.

Kinetic Evidence for Nucleus Cluster Formation in Solid Decompositions

OVERALL topokinetic equations can be extended to take account of time-dependent nucleation functions other than the random law modified by ingestion[1,2]; but no analytic treatment of non-random spatial arrangements of nucleation sites has appeared. Apart from photo-micrographs of partially decomposed barium azide showing barium nuclei in clusters and arrays[3,4], and some single crystal investigations[5], there is little published evidence of the need for such a theoretical extension. However, recent kinetic evidence has suggested the existence of non-random arrangements of two kinds.

First, work on α-lead azide[6] and nickel oxalate[7], described elsewhere, in which the kinetic form of the accelerator period changes at $\alpha \sim 0{\cdot}25$ from a cubic towards a parabolic dependence, is consistent with linear arrays of three-dimensional nuclei which coalesce to form rod-like bodies. Secondly, in some preparations of silver oxide[8] and silver oxalate[9] a cubic dependence holds for $\alpha > 0{\cdot}05$ with negative deviations for $\alpha < 0{\cdot}05$, the intercept t_0 of the $\alpha^{1/3}$ versus t plot being negative.

This second kinetic form can arise from the growth of nuclei in isolated planar groups. The constituent nuclei first grow independently giving a linear $\alpha^{1/3}$ versus t plot, but later coalesce giving a nearly linear plot with a reduced slope, the number of nuclei in a group being given by the cube of the ratio of the initial and final slopes of the $\alpha^{1/3}$ versus t plot. For the data on a range of neutron-irradiated silver oxalate samples[9] plotted on a reduced time

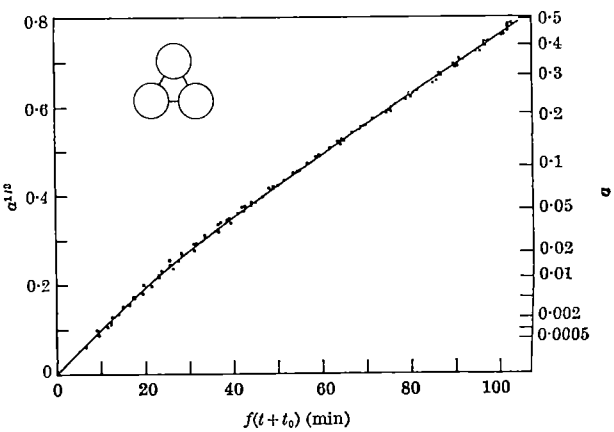

Fig. 1. The reduced plot $\alpha^{1/3}$ versus $f(t+t_0)$ for the thermal decomposition at 126° C of neutron-irradiated silver oxalate. The full line represents the volume development of an equilateral cluster. Data from Fig. 7 of ref. 9

axis in Fig. 1, this ratio is 1·4, thus the groups contain three nuclei. The full line represents the growth of three hemispherical nuclei at the apices of an equilateral triangle with proper allowance for single and multiple overlap. Calculations for three nuclei in a straight line do not accord with this.

A non-random arrangement of nuclei is thus adequate to explain these kinetic features. It is not necessary to introduce non-isothermal conditions or rapid growth of small nuclei.

Brown (β) Titanium Trichloride

Recent papers by Clark[1] and Dijkgraaf[2] have shown that α-$TiCl_3$ may be distinguished from β-$TiCl_3$ by differences in the reflectance spectra of the two solids. In particular, the band at 19,000 cm^{-1} in the violet (α) form is replaced by a band at 24,000 cm^{-1} in the brown (β) form.

I have now found that the violet and brown aqueous acid solutions of the respective α and β forms can be distinguished from one another by absorption maxima at frequencies similar to those of the two solids (Table 1).

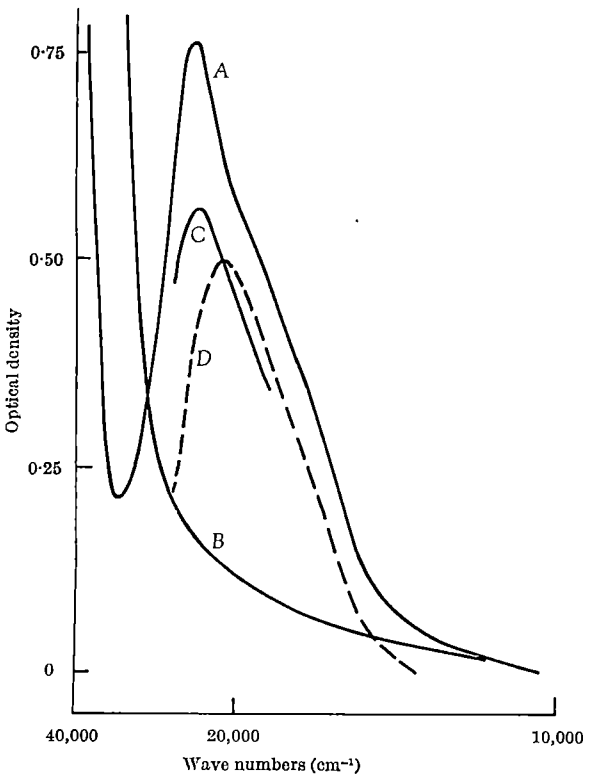

Fig. 1. Oxidation and reduction of a solution of brown (β) $TiCl_3$ (9·6 mg/ml. in 1·3 N sulphuric acid)

A, fresh solution; *B*, solution *A* after passage of oxygen for 30 min; *C*, solution *B* after cathodic reduction; *D*, solution *B* after prolonged oxidation and subsequent cathodic reduction

Table 1. Absorption Spectra of $TiCl_3$ in 1·3 N Sulphuric Acid

Form	Concentration (mg/ml.)	Wave numbers of absorption maxima ($cm^{-1} \times 10^{-2}$)		Colour
α	12·0	198 (Σ 3)	161*	Violet
β	9·6	233 (Σ 14)	178*	Brown

* Indicates an inflexion on a larger curve; Σ indicates extinction coefficient per 154 g of solute.

Distinctive spectra can also be obtained from solutions of the two forms in ethanol and acetonitrile.

These observations suggest that β-$TiCl_3$ preserves some of its distinctive structure in solution even when the medium is strongly solvating. A remarkable example of the stability of this relic structure is provided by a solution of β-$TiCl_3$ which has been subjected to an oxidation-reduction sequence (Fig. 1). It could well be assumed that such a succession of chemical reactions would convert any trivalent titanium into its most stable form; indeed, after anodic oxidation for several days the violet coloration of α-$TiCl_3$ is produced on cathodic reduction. If, however, the duration of the oxidized stage is limited to 1 h, it is surprising to find that the brown coloration is restored by cathodic reduction.

Further work on the structure of β-$TiCl_3$ is in progress.

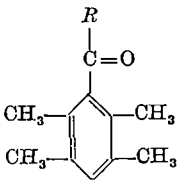
Tetracyanoethylene Complexes as Indicators of the Carbonyl Inductive (−*I*) Effect in Sterically Hindered Aromatic Ketones

It is well established that the conjugation of the carbonyl group with the aromatic π-electron system in alkyl phenyl ketones (I, $R' = R'' = H$) is not hindered by the substitution of one methyl group in the *ortho*-position (I, $R' = CH_3$, $R'' = H$).

I

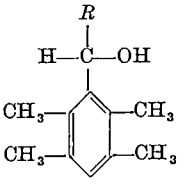
However, two such *ortho*-substituted methyl groups (I, $R' = R'' = CH_3$) force the oxygen of the carbonyl group out of the plane of the aromatic ring and so suppress carbonyl-ring conjugation. This is shown by the large diminution in the intensity of the ultra-violet absorption in the region 210–300 mμ, in the 2,6-dimethyl compounds, relative to the 2-methyl- and unsubstituted compounds[1].



In principle, it should be possible to separate the inductive effect (−*I*) of the carbonyl group (independent of conjugation) from its mesomeric effect (−*M*) (dependent on conjugation) in several ways and so to observe the inductive effect independently in compounds of this type. Dipole moment investigations have achieved this[2]. Thus the moments of 2-methylacetophenone and 2,6-dimethylacetophenone are respectively 3·22 D (−*I* and −*M* operating) and 2·81 D (−*I* only operating).

Hammett σ-value investigations have also been directed to this general problem. Thus the value ($\sigma_p - \sigma_m$) generally gives a semi-quantitative measure of the separate effects, but this is only approximate[3].

It was shown in 1937 by dipole moment investigations[2c] that conjugation between the nitro-group and the aromatic ring in nitrodurene (3-nitro-1,2,4,5,-tetramethylbenzene) is suppressed because the oxygen atoms of the nitro-group are forced out of the plane of the ring by the steric hind-



rance of the vicinal 2- and 4-methyl groups. The dipole moments of nitrobenzene and nitrodurene are, respectively, 3·95 D ($-I$ and $-M$ operating) and 3·39 D ($-I$ only operating).

Clearly, by analogy with 3-nitrodurene and with alkyl 2,6-dimethylphenyl ketones, alkyl duryl ketones (II) should exhibit suppression of conjugation between the carbonyl group and the aromatic ring. With this in mind, we have prepared a series of 3-acylated durenes (II; R = n-C_3H_7, n-C_4H_9, n-C_5H_{11}, $(CH_3)_2CH$) and examined them by a variety of spectroscopic means.

II

The ultra-violet absorption spectra of these compounds indicate the absence of carbonyl conjugation, since high-intensity absorption is not present in the region 210–300 mμ. The proton magnetic resonance spectrum of durene shows two singlet peaks (τ 3·4, τ 8·0), the former due to the two aromatic protons, the latter due to the twelve equivalent protons of the four methyl groups. The 3-acyldurenes, however, show two distinct aromatic methyl proton peaks, one unchanged at τ 8·0 (two methyl groups) and the other (two methyl groups) displaced about 0·2 p.p.m. downfield. This difference is ascribed partly to the inductive effect of the carbonyl dipole on the *ortho* methyl groups and partly to long-range deshielding by the diamagnetic anisotopic carbonyl field, there being virtually no effect on the *meta* methyl groups. The aromatic methyl protons in methyl *o*- and *m*-toluate have τ values 7·15 and 7·73 respectively, the downfield displacement in the former compound of 0·58 p.p.m. being presumably due to the *ortho* carbonyl group where the mesomeric effect may also operate[4]. In accordance with this interpretation, the secondary alcohols (III) corresponding to (II) show proton-magnetic resonance spectra in which the peaks due to *ortho* and *meta* methyl groups are separated by only 0·05 p.p.m.

III

It has been shown that tetracyanoethylene (TCNE) is a sensitive indicator of π-electron availability[5]. Charge-transfer complexes were therefore formed by mixing equivalent amounts of TCNE and the above acyldurenes in methylene chloride solution. Durene itself forms a deep red complex (λ_{max} 481 mμ) while the acylated durenes all show a paler colour (λ_{max} about 440 mμ). That this is not due to steric inhibition of complex formation is shown by the fact that the corresponding alcohols (III) show the same deep colour as durene itself (λ_{max} about 490 mμ).

Thus the acyldurene–TCNE complexes appear to indicate a π-electron deficiency in the aromatic ring with respect to durene[1b], and since the ultra-violet and proton-magnetic resonance spectra of the acyldurenes indicate very little if any mesomeric effect, this must be ascribed largely to the inductive effect of the carbonyl dipole.

3-Acyl durenes (II)[(R = n-C_3H_7, n-C_4H_9, n-C_5H_{11})] were prepared by Friedel–Crafts acylation of durene using the corresponding acid chlorides (1·2 mole) in carbon disulphide below 0°. The compound (II) (R = $(CH_3)_2CH$) was prepared by Friedel-Crafts acylation of durene with isobutyric anhydride (1·2 mole) in carbon disulphide at room temperature. All were colourless. 3-*Butanoyldurene* (II; R = n-C_3H_7) found: C, 82·55; H, 9·95; $C_{14}H_{20}O$ requires C, 82·35; H, 9·8 per cent: m.p. 37°. 3-*Pentanoyldurene* (II; R = n-C_4H_9) found: C, 82·85; H, 10·2; $C_{15}H_{22}O$ requires C, 82·55; H, 10·1 per cent: m.p. 40°. 3-*Hexanoyldurene* (II; R = n-C_5H_{11}) found: C, 82·65; H, 10·35; $C_{16}H_{24}O$ requires C, 82·75; H, 10·35 per cent: m.p. 62°. 3-*Isobutanoyldurene* (II; R = $(CH_3)_2CH$) found: C, 82·25; H, 9·95; $C_{14}H_{20}O$ requires C, 82·35; H, 9·8 per cent: m.p. 49°.

The ultra-violet absorption spectra were recorded on a Unicam *SP* 700 spectrophotometer; the proton-magnetic resonance spectra on a Perkin–Elmer 60 *Mcs* spectrometer.

BIOCHEMISTRY

Isozymes of Salivary Amylase

It has previously been observed that crystalline salivary amylase gives two peaks in free electrophoresis[1]. The work recorded here shows that a sample of salivary amylase crystallized three times, which gave a single peak in the ultracentrifuge (Fig. 1), could be separated into four bands by disk electrophoresis on polyacrylamide gel[2] (Fig. 2).

The amylase was prepared according to a method previously described[1]. The crystals were dissolved at *p*H 10·1 by addition of ammonia, brought to *p*H 8·6 with acetic acid (final ionic strength 0·19) and centrifuged at 59,780 r.p.m. at 7·1° C in a Spinco model *E* ultracentrifuge. (We thank Dr. G. W. de Villafranca for the use of the ultracentrifuge.)

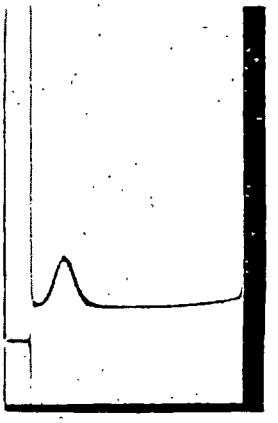

Fig. 1. Ultracentrifugation of salivary amylase, 4·9 mg/ml., *p*H 8·5, 0·19 ionic strength, 45 min at 59,780, 7·1° C in Spinco model *E* ultracentrifuge

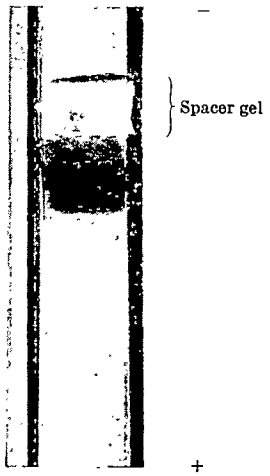

Fig. 2. Gel-electrophoresis of salivary amylase on polyacrylamide gel (Canalco) 1 h at 2·5 m. amp/tube. Buffer 0·05 M *tris* (hydroxymethyl) aminomethane, 0·384 M glycine, *p*H 8·3 (*p*H in the column during electrophoresis in this buffer is 9·5). 200 μg amylase (same preparation as in Fig. 1) on 0·5 cm × 6 cm column. Spacer gel on top, migration towards anode at bottom. Amido black staining

Disk electrophoresis was performed in a Canalco model 12 apparatus according to the method of Ornstein and Davis[2] as further elaborated in the Canalco instructions. The pattern shown in Fig. 2 was obtained on the same solution as that used for ultracentrifugation. Three bands show clearly in the photograph and a fourth faint band is discernible.

Amylase activity was determined in unstained columns run simultaneously with comparable columns which were stained with amido black at the end of the run. The unstained columns were frozen immediately after termination of the electrophoresis. They were cut in 1 mm slices and each slice was extracted with 0·5 ml. buffer of *p*H 6·8, 0·02 M phosphate, 0·045 M sodium chloride. The slices were crushed and shaken mechanically in the buffer for 3–4 h. Activity was determined on the basis of the starch iodine colour[1] and the amount of amylase calculated from the relation between amylase concentration and activity[3]. Further attempts to improve the method of extraction did not increase the recovery, which was 60–85 per cent of the activity of the amylase applied to the column.

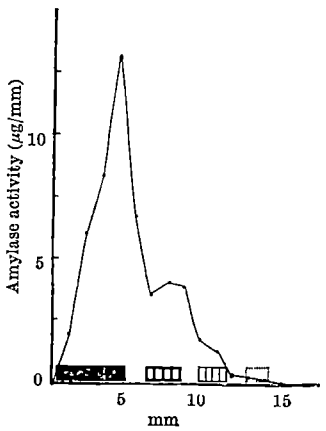

Fig. 3. Comparison of amylase activity and amido black staining of two polyacrylamide gel columns run simultaneously. Conditions as in Fig. 2 except 3 h run, 82 μg amylase. Migration towards anode at right. Position of the four protein bands and the intensity of staining represented by blocks at base of graph

In Fig. 3 the distribution of the amylase activity is compared with the position of the stained protein bands. The two columns were run simultaneously at *p*H 9·5 in the Canalco buffer, 0·384 M glycine, 0·05 M *tris* (hydroxymethyl) aminomethane, for 3 h at about 2·5 m.amp/column. The most slowly moving band is the broadest, the most strongly stained, and it gave the highest amylase activity. The bands became progressively narrower and less deeply stained toward the anode. The activity follows the same trend and even the faint, fastest moving band manifested amylase activity. The use of parallel columns for staining and activity introduces some uncertainty in the comparison. For a total spread of the four bands of 15 mm, duplicate stained columns may show 0·5 mm differences in the width of the bands and 1–2 mm difference in the total spread. The gel between the two slowest bands is more deeply stained than the weakest band, so that there is never complete separation of the bands. There is also some distortion during the cutting, and the staining procedure may alter the length of the column. However, the same general distribution of protein bands and amylase activity has been found with several amylase preparations. There may be some variation in the relative amounts found in each band; for example, the preparation shown in Fig. 2 had relatively less of the slowest-moving component than that of Fig. 3.

The use of methods such as electrophoresis in a supporting medium or chromatography has, in recent years, revealed the presence of several fractions in many enzymes which appeared homogeneous by other criteria such as ultracentrifugation. In the case of salivary amylase, Millin and Smith[4] obtained three fractions by chromatography on a calcium phosphate column. Fresh saliva was first separated into two fractions on 'Sephadex *G*25' and the amylase-containing fraction was rechromatographed on calcium phosphate using a discontinuous elution system of increasing concentrations of phosphate buffer. Five protein fractions were obtained and three of these had amylase activity, but none of the fractions seemed to represent single proteins. The three chromatographic fractions of amylase were obtained when saliva from a single individual was used. We have repeated and confirmed these observations, but have not yet had an opportunity to compare these fractions with the electrophoretic fractions. Our crystalline preparation originated from pooled saliva and the possibility remains that there are differences among the amylases secreted by different individuals. Millin and Smith observed that one of their three fractions was unstable. They, therefore, suggested that the two peaks found in our laboratory on free electrophoresis of the crystalline enzyme[1] was due to the loss of one fraction during preparation. Since four components have now been separated by gel-electrophoresis, loss of a particular fraction does not need to be presumed.

Patton and Pigman[5] found up to twelve components of parotid gland secretion by free electrophoresis and showed that one of these contained amylase activity. This might indicate that the different salivary glands each produce a slightly modified enzyme, though in their system it would be difficult to distinguish two or more components of amylase. In spite of the three chromatographic fractions found in fresh saliva, changes in the amylase during preparation of the crystalline enzyme, such as the partial deamination observed in insulin by Carpenter and Hayes, cannot be excluded[6]. Tsugita and Akabori's finding that 'Taka' amylase contains bound carbohydrate[7] prompted us to look for bound carbohydrate in salivary amylase. The anthrone test and the tests for hexosamine and sialic acid were performed[8,9]. All three gave results that corresponded to less than one-third of a group per mole of amylase, assuming 50,000 as the molecular weight[10]. This might well represent a small amount of mucin which had not been completely removed, but it might also mean that one fraction of the amylase contains carbohydrate, a situation similar to that observed by Plummer and Hirs for ribonuclease[11]. While the molecular weight of salivary amylase is usually assumed to be 50,000, the amino-acid composition[12] fits a minimum molecular weight of 18,000 to within ± 3 per cent of all the amino-acid but histidine (−5 per cent). This leaves the possibility

that the situation is similar to that of lactic dehydrogenase[13] and that the amylase might be a trimer of two very similar proteins. This could give rise to four fractions.

Uncouplers of Oxidative Phosphorylation and Teratogenic Activity of Insulin

TREATMENT with insulin has well-established teratogenic effects in chick development. When administered during the earliest stages of incubation (first 2 days), it is responsible for the occurrence of rumplessness (chiefly absence of the tail vertebræ), whereas somewhat later (4th or 5th) day) it leads to a syndrome of micromelia and abnormalities of the beak (namely, a shortened upper beak or parrot beak). During these later stages, but not in the early ones, the teratogenic activity of insulin is strikingly exaggerated by the simultaneous administration of chlorpromazine[1]. The amounts of chlorpromazine which produce this effect were non-teratogenic and only moderately toxic if given alone.

When we reported these observations, we suggested that uncoupling of oxidative phosphorylation by chlorpromazine might well play an important part in bringing about the teratogenic synergism which follows combined administration of the two compounds. This seemed the more suggestive since Randle and Smith had advanced persuasive arguments for assigning to insulin also the role of an uncoupling agent in energy transfer[2,3]. It seemed important, therefore, to enquire if other compounds which serve as uncouplers of oxidative phosphorylation potentiate the teratogenic activity of insulin in a way similar to that observed for chlorpromazine.

The tests recorded here were conducted with four compounds for which uncoupling of oxidative phosphorylation is well known, namely, sodium salicylate, 2.4-dinitrophenol (DNP), *p*-hydroxymercuribenzoate (PHMB) and carbonyl cyanide *m*-chlorophenylhydrazone. Reasons for these choices, in addition to solubility in water and compatibility with adequate embryo survival, will be discussed later.

The results obtained with salicylate are given in Table 1. In the control group receiving 10 mg/egg salicylate at 96 h the immediate post-operative mortality was moderate, many of the hatched chicks (23·5 per cent) showed a marked opisthotonus, but the incidence of gross malformations among survivors of the 13th day was very low, the most conspicuous effect being a shortened upper beak (2·6 per cent). The same amount of salicylate, given in combination with 1·5 I.U. insulin, led to a great rise in embryo mortality and to a dramatic exaggeration in incidence of the malformations typically produced by insulin. Too few chicks hatched in this group to determine if the reduced incidence of opisthotonus (7·1 per cent) differed significantly from that observed among the salicylate controls. In regard to synergism with the teratogenic activity of insulin, salicylate was similar to chlorpromazine. It is of interest that according to Lane and Eshleman a high incidence of shortened upper beak occurs after treatment (at 96 h) with larger doses of salicylate than those used by us and that, except for curling of the toes, this was the only marked morphological defect[4].

Table 1. Results of experiments in which either insulin or sodium salicylate or both compounds were injected into the yolk sac of eggs of White Leghorn fowl after 96 h of incubation

Insulin (I.U.)	1·5	1·5	—
Sodium salicylate (mg)	—	10·0	10·0
Treated	292	273	295
Mortality per cent			
to end sixth day	25·7	54·6	9·5
7–13	2·7	10·3	12·9
14–22	27·4	30·0	48·8
Hatched per cent	44·2	5·1	28·8
Survivors of thirteenth day	209	96	229
Normal per cent	80·4	37·5	86·0
Micromelia per cent	14·8	44·8	1·3
Parrot or short lower beak per cent	5·7	21·9	0·4
Short upper beak per cent	3·3	19·8	2·6
Opisthotonus among hatched chicks per cent	—	7·1	23·5
Miscellaneous defects per cent	5·3	1·0	0·9

The data for experiments with 2,4-dinitrophenol are shown in Table 2. The injection of 100 γ/egg DNP at 96 h was non-toxic, the chicks hatching quite normally, and it was also non-teratogenic. When the same amount of DNP was combined with 1·5 I.U. insulin, embryo mortality during the first 48 h following treatment was three times that occurring after insulin alone. The incidence of micromelia and parrot beak was unaffected among survivors of the 13th day; but the frequency of shortened upper beak was raised more than thirteen-fold.

Table 2. Results of experiments in which either insulin or 2,4-dinitrophenol or both compounds were injected into the yolk sac of eggs of White Leghorn fowl after 96 h of incubation

Insulin (I.U.)	1·5	1·5	—
2,4-dinitrophenol (γ)	—	100	100
Treated	184	281	185
Mortality per cent			
to end sixth day	17·9	53·0	3·2
7–13	3·8	0·7	2·2
14–22	26·1	23·5	18·3
Hatched per cent	52·2	22·8	76·2
Survivors of thirteenth day	144	130	175
Normal per cent	84·0	70·8	97·7
Micromelia per cent	15·3	15·4	0·0
Parrot or short lower beak per cent	4·2	3·8	0·0
Short upper beak per cent	1·4	18·5	0·0
Miscellaneous defects per cent	2·1	3·8	1·7

In a third series of tests we used *p*-hydroxymercuribenzoate (PHMB) alone or in combination with insulin. Injection of 0·5 mg PHMB at 96 h was only slightly toxic and produced an incidence of 2·5 per cent micromelia and beak defects; with one-tenth of this dose, that is, 50 γ/egg, PHMB was non-toxic and non-teratogenic. When 50γ PHMB were administered in combination with 1·5 I.U. insulin, the incidence of micromelia was significantly increased over that found after insulin alone, but there was no significant change in the frequency of beak defects.

Finally, we experimented with carbonyl cyanide *m*-chlorophenylhydrazone[5,6]. Five and 15 γ/egg of this compound were tested alone and in combination with 1·5 I.U. insulin. Both dosages were well tolerated and non-teratogenic when given alone. Both amounts greatly raised embryo mortality when used together with insulin, but there was no effect whatever on incidence of malformations.

We have now tested the effects on the teratogenic activity of insulin exerted by five compounds which are known to interfere with coupled oxidative phosphorylation. Two of these compounds, namely, chlorpromazine and sodium salicylate, produce synergistic results over the whole spectrum of insulin teratogenicity (at the 96-h stage) as shown by a great exaggeration in the incidence of malformations of the appendicular as well as the facial

skeleton. In combination with 2,4-dinitrophenol the frequency of insulin-induced defects of the maxilla was greatly raised, but the incidence of other abnormalities remained unaffected. When the administration of insulin was combined with that of *p*-hydroxymercuribenzoate, the results were the opposite to those just discussed, that is, the teratogenic effect of insulin on long bone development (micromelia) showed potentiation, but the incidence of abnormalities of the facial skeleton was not influenced. There was, finally, no quantitative alteration in the teratogenic effects of insulin by the added administration of carbonyl *m*-chlorophenylhydrazone.

It has been clearly shown "that chlorpromazine and dinitrophenol act at different points in the sequence of phosphorylation reactions"[7], and it seems likely that multiple loci of such interference exist[8]. This is in good agreement with our findings. There is also much evidence for similarities between insulin and uncoupling agents in their effects on metabolic events, and especially on dehydrogenase activity[9,10]. It is true that the uncoupling agents are not altogether specific for the enzymatic events of oxidative phosphorylation[11], but since many of our earlier observations had already pointed to interference with dehydrogenase activity as the most likely primary step by which insulin interferes with normal development[12], the present results may be taken as strong supporting evidence. The recent conclusion by Eisenhardt and Rosenthal[13] that "uncoupling agents operate by interfering with the synthesis of high-energy intermediates" may well apply to our material.

We thank Dr. P. G. Heytler, Central Research Department, E.I. du Pont de Nemours and Co., Wilmington, Delaware, for providing the carbonyl cyanide compound used in our tests. This work was supported by a grant from the U.S. National Science Foundation.

Metabolic Fate of some Chlorinated Phenoxyacetic Acids in the Stem Tissue of *Avena sativa*

AN extension of the previous work[1] on the hydroxylation of phenoxyacetic acid by mesocotyl tissue of *Avena sativa* has demonstrated a broad relationship, at least along one pathway of metabolism, between the fate of certain phenoxyacetic acids and their pattern of ring substitution.

The techniques used are the same as those already reported. All metabolites were isolated in mg quantities by solvent extraction followed by chromatography. Characterization of the metabolites or their derivatives was by comparison with authentic compounds.

Phenoxyacetic acids with an unsubstituted 4 position were hydroxylated at that position, and the resulting phenolic acid was accumulated as the 4-0-β-D glucoside. Thus 2-chlorophenoxyacetic acid was converted into a more polar compound which could be hydrolysed with acid or β-glucosidase to glucose and a phenolic acid (m.p. 146° C). The acid showed selective light absorption in the ultra-violet region, λ_{max} 288 mμ at *p*H 2; λ_{max} 306 mμ at *p*H 12. This phenolic acid corresponds exactly, both in terms of these characteristics and the infra-red spectrum, with 2-chloro-4-hydroxyphenoxyacetic acid[2].

Similarly 2,6-dichlorophenoxyacetic acid was converted into a glucoside which yielded glucose and a phenolic acid on acid or enzymatic hydrolysis. Elementary analysis of the ammonium salt of this glucoside supports the formulation as a mono glucoside of a phenolic acid derived from 2,6-dichlorophenoxyacetic acid (found: C, 39·2; H, 4·77; Cl, 16·65; calc. for $C_{14}H_{19}NO_9Cl_2$: C, 40·5; H, 4·6; Cl, 16·87). This phenolic acid had λ_{max} 283, 287 mμ at *p*H 2 and λ_{max} 302 mμ at *p*H 12 and was identical in these respects with authentic 2,6-dichloro-4-hydroxyphenoxyacetic acid.

In contrast, phenoxyacetic acids with a chlorine atom at position 4 were not hydroxylated to any appreciable extent, but neutral products were obtained which proved to be substituted phenoxyacetylglucoses. Compounds of this type were obtained from 4-chlorophenoxyacetic acid and 2,4-dichlorophenoxyacetic acid (2,4-D). The ultra-violet spectra of these metabolites were identical with their parent acids. The infra-red spectrum of the 2,4-D metabolite exhibited strong absorption at 3,300 cm^{-1} and 1,050–1,100 cm^{-1} characteristic of hydroxyl groups in the sugar moiety. Acid or enzymatic hydrolysis yielded equimolar quantities of glucose and the parent acid. The 2,4-D metabolite was obtained in the crystalline form, and was acetylated to give a material having an infra-red absorption spectrum identical with that of 1-0-2,4-dichlorophenoxyacetyl - 2,3,4,6 - tetraacetyl - β - D - glucose, which was obtained by condensing tetraacetylbromoglucose with the silver salt of 2,4-D.

The metabolic fate of 2,4,6-trichlorophenoxyacetic acid is exceptional: hydroxylation occurs at position 3 and the glucoside was isolated. Enzymatic hydrolysis yielded a phenolic acid having λ_{max} 291 mμ at *p*H 2 and λ_{max} 308 mμ at *p*H 12 identical with synthetic 3-hydroxy-2,4,6-trichlorophenoxyacetic acid.

In the case of 2,6-dichlorophenoxyacetic acid, in addition to the glucoside already described, a glucose ester of the unchanged acid was isolated.

Since the hydroxylation of auxins, benzoic acid, and cinnamic acids has been demonstrated by other workers[3–5], there can be little doubt that an enzyme system capable of effecting this transformation exists in plant tissues.

We thank Prof. G. E. Blackman for his advice.

Detection of 'Activated' Compounds on Paper

THE presence of acylating compounds on paper is frequently deduced from reaction with hydroxylamine and subsequent treatment with ferric chloride to reveal the hydroxamates so formed. This method has been used for the detection of nucleotide peptides and similar 'activated' complexes[1–8].

During attempts to characterize the products of a yeast enzyme system reported to form 'activated' peptides[9,10] colours were observed after spraying chromatograms or electropherograms with ferric chloride irrespective of any previous treatment with hydroxylamine. It is well known that ferric ions form coloured complexes with a variety of functional groups; accordingly, a large number of compounds were tested with ferric chloride and hydroxylamine on paper under various conditions.

Typical results are listed in Table 1. It is clear that many substances react with ferric chloride alone and that the colours are usually intensified after treatment with hydroxylamine, particularly in the presence of borate, *p*H 7·7 (cf. ref. 4). Small amounts of genuine hydroxamates may perhaps be formed from amino-acids under these conditions[12]. All the common amino-acids were tested, and most gave some colour with ferric chloride alone. Only cysteine, leucine and phenylalanine failed to give colours under any of the conditions tried. A series of dipeptides of glycine were also tested and gave reactions similar to those of the C-terminal amino-acid. Representative amides, esters, uronic acids and lactones, substances known to form hydroxamates[13–18], were also tested and examples are included in Table 1. The purple colour produced by the genuine hydroxamates is fairly characteristic, but the test for hydroxamate formation on paper is of doubtful significance except when a duplicate paper gives little or no reaction with ferric chloride alone.

Table 1. Reactions on Paper of Various Compounds with Ferric Chloride and Hydroxylamine

Compound	*A*		*B*		*C*	
Aspartic acid		—		—	+	P
Glutamic acid	+ + +	R–B	+ + +	R–B	+ + +	R–B
Glycine	+ +	R–B	+ +	R–B	+ + +	R–B
Methionine	[+]	O–P	+	O–P	+	O–P
Cytosine		—	[+]	Blue	[+]	Blue
Guanine	[±]	Pink		—	+	P
Yeast RNA	+	G	+	G	+	G
Arabinose		—	±	Pink	±	Pink
Glucose		—	+	B	+ +	Pink
Glucosamine hydrochloride	+	Y	+	P	+	P
Ascorbic acid	+	P	+ +	P	+ +	P
Pyruvic acid	+	B	+ +	P	+ +	P
Imidazole	+ + +	O–B	+ +	P	+ + +	P
Glutamine		—	+ +	P	+ + +	P
Glucuronic acid		—	+	P	+	P
1,5-Gluconolactone		—	+ +	P	+ +	P
Triacetin		—	+ +	P	+ +	P

Treatment of paper: *A*, sprayed with ferric chloride reagent[1] only; *B*, sprayed lightly with 0·1 M acetate buffer, *p*H 4·0, then sprayed with salt-free hydroxylamine[11], heated at 60° for 5 min, then sprayed with ferric chloride; *C*, sprayed lightly with 0·05 M borate buffer, *p*H 7·7, followed by hydroxylamine and ferric chloride. [ ] Colour appears overnight. P, purple; G, Grey; R–B, red-brown; O–B, orange-brown; O–P, orange-pink; Y, yellow changing to brown; B, buff changing to pink.

With regard to the colours produced on electropherograms of yeast extracts[1,4] it has now been found that these can be readily reproduced by electrophoresis of mixtures of amino-acids especially after evaporation of the latter in the presence of acetate buffer. An aqueous ethanolic extract of yeast was prepared and subjected to electrophoresis as described by Harris and Wiseman[4]. For comparison a mixture of tryptophan, threonine, asparagine, aspartic acid, glutamic acid and lysine (10 mg of each) was taken up in 25 ml. of 0·1 M acetate buffer, *p*H 5·0, and the mixture concentrated to 2·0 ml. by rotary evaporation. After centrifugation a sample of the supernatant solution was electrophoresed under the same conditions. The two electropherograms were virtually indistinguishable under ultra-violet light, after spraying with ninhydrin and after the hydroxylamine–ferric chloride test. Both exhibited patterns very similar to those described for the yeast extract by Harris and Wiseman[4]. In addition, closely similar pink-brown colours were observed on duplicate papers treated with ferric chloride alone.

Substances reacting with hydroxylamine to form genuine hydroxamates are certainly present in the yeast extracts as judged by the reaction in solution, where it is possible to control conditions more precisely and to examine the spectral characteristics of the product. Their specific detection on paper, however, is virtually impossible in the presence of materials which react with ferric chloride in a non-specific manner. Extensive fractionation[2,3] is clearly necessary before any reliance can be placed on the hydroxylamine–ferric chloride test.

We thank Dr. A. H. Cook for his advice.

Paper Electrophoresis of Heat-treated Serum Albumin in the Presence of Congo Red

It is known that if the specific spatial arrangement of the peptide chains of some proteins, such as egg albumin and serum albumin, is altered by heat, they coagulate and lose many of their specific properties. This phenomenon of denaturation is generally irreversible.

Van der Scheer and associates[1] demonstrated electrophoretically the formation of a colloidal component *C* in normal horse serum which had previously been heated to 65°. As Beilinsson[2] and Ball *et al.*[3] had shown that the coagulation of egg albumin by heat could be prevented by treating the albumin solution with sugars and sugar alcohols, it was thought that a similar treatment of blood serum and plasma might also prevent coagulation and even prevent the formation of the *C* component. Hardt *et al.*[4] demonstrated that heat coagulation and the formation of the *C* component were prevented when bovine plasma was saturated with D-glucose. Later the same workers[5] compared the effects of some monosaccharides and mannitol as well as D-glucose in plasma and serum on the formation of the *C* component. Haurowitz *et al.*[6] showed that heat-treated ovalbumin and serum albumin combine with congo red to form complexes which remain red at *p*H 2, while mixtures of congo red with the unheated proteins have a purplish colour at *p*H 2, and the denatured protein combines with more congo red than the native protein.

The work recorded here describes the effect of congo red on the coagulation and the paper electrophoretic behaviour of beef serum albumin.

Serum albumin coagulates when it is heat-treated in boiling water and then does not migrate on paper electro-

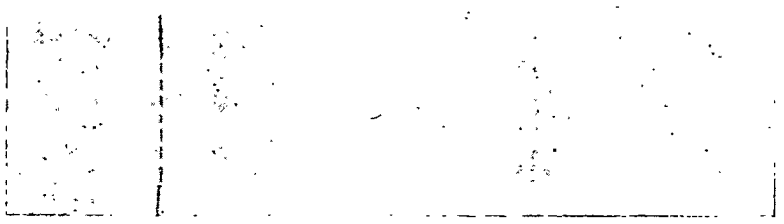

Fig. 1. The migration of serum albumin heated with congo red at (*p*H 6·4) The photograph was taken using a red filter to remove the red colour of congo on the strip

phoresis. But according to our unpublished experiments, it remains clear and migrates when it is heat-treated in alkaline solution. We now find that albumin also remains clear and migrates when it is heat-treated in the presence of congo red. The aqueous solution of congo red is alkaline (about *p*H 10). But albumin also remains clear and migrates when it is heat-treated with congo red acidified to *p*H 6·4, whereas it coagulates and does not migrate when it is heat-treated without congo red at the same *p*H.

In our experiments albumin was prepared by isolation from beef serum using ammonium sulphate[7]. The precipitate was dialysed to remove the salts, the albumin content (2·2 per cent) was determined refractometrically and the *p*H (5·8) electrometrically. To 100 mg congo red in aqueous solution was added 6·3 ml. of 0·1 N sulphuric acid and the volume made up to 50 ml. with water. In two test-tubes were put 1 ml. (22 mg) of serum albumin; to one was added 5 ml. of acidified congo red solution and to the other 4·9 ml. of water and 0·1 ml. of 0·01 N sodium hydroxide to adjust the *p*H to 6·4. The two tubes were then heated in a boiling-water bath for 15 min and cooled. The mixture containing congo red was clear while the other was coagulated. The *p*H value of the dye-containing mixture was 6·4 after heating. Paper electrophoresis of the dye-containing mixture, using an L.K.B. type *B* apparatus with barbitone–sodium barbitone buffer, *p*H 8·6, 225 V and ionic strength 0·1, was carried out for 7 h. The strips were then dyed with bromo-phenol blue, washed and dried. Fig. 1 shows the migration of albumin heated with congo red at *p*H 6·4. The experiments show that congo red prevents coagulation of serum albumin at *p*H 6·4 and permits paper-electrophoretic migration of the protein heat-denatured in this way.

Biliary Phospholipids in Various Species

While carrying out investigations on the fatty acids of bile and plasma lecithins differences were noted in the overall biliary phospholipid pattern in man, dog, rat and ox.

Bile lipids were extracted, separated and analysed by previously described methods[1]. Purity after silicic acid column chromatography was checked by thin-layer[2] and paper chromatography[3]. Phospholipid standards were prepared from rat liver and red blood cells according to the methods of Glenn *et al.*[4] and Spitzer and Balint[5].

Lipid extraction with chloroform–methanol[6] or by refluxing with hot ethanol–ether yielded similar results.

The distribution of phospholipids obtained is shown in Table 1. Compounds noted as trace amounts could only be detected by thin-layer chromatography. Besides the phospholipids indicated, trace amounts of what appeared to be cardiolipin and phosphatidic acids were also detected in the four species examined. The final identification of all compounds was based on comparison with standards using thin layer or paper chromatography. The phosphorus-to-ester ratio determined on the lecithins of the species examined gave an average value of 1 : 1·88 (range 1 : 1·71–1 : 2·10).

The results obtained in this work confirm those of Turner[8], Isaksson[9] and Nakayama and Blomstrand[10] that the major phospholipid of bile is lecithin. The detection of phosphatidyl ethanolamine and lysolecithin in human bile also confirms the work of others[8–10].

Isaksson[9], in his work on bile from man, dog and ox, concluded that lecithin was the only phospholipid present. The results obtained in this work indicate a more complex phospholipid pattern. The detection of phosphatidyl inositol and sphingomyelin by Nakayama and Blomstrand[10] in human bile could not be confirmed.

Table 1. Average Percentage Distribution of Bile Phospholipids

Compound	Man (10*)	Rat (4)	Dog (3)	Ox (2)
Phosphatidyl ethanolamine	3·6	6·0	*N.D.*†	1·1
Phosphatidyl serine	*N.D.*	*N.D.*	1·8	1·2
Phosphatidyl inositol	*N.D.*	Trace	Trace	Trace
Lecithin	92·2	92·2	95·8	89·8
Sphingomyelin	*N.D.*	Trace	2·3	*N.D.*
Lysolecithin	3·9	Trace	*N.D.*	7·8

* No. of animals.
† *N.D.* not detected.

The phosphorus-to-ester ratio of less than 1 : 2 obtained for lecithin is consistent with the reported presence of choline plasmalogens[10]. Attempts at a similar elucidation of the phosphatidyl ethanolamine and phosphatidyl serine proved unsuccessful, due to bile pigments in these fractions interfering with the hydroxylamine reaction in determining ester linkages.

The results presented indicate that there are species differences in the phospholipid composition of bile. In all species examined, lecithin was the major phospholipid amounting to 90 per cent or more of the total. It is difficult to assign any significance to the differences noted at this time. This project was supported by grant *AM*-07563-02 from the National Institutes of Health, U.S. Public Health Service.

PHYSIOLOGY

Simulation of a Neuronal Network operating Rhythmically through Recurrent Inhibition

A SYNCHRONOUS afferent volley initiates a series of rhythmic discharges in the ventrolateral nucleus in the thalamus[1], due to repetitive activity in a recurrent inhibitory pathway of the thalamic neurones[2]. A similar pattern of rhythmic activity occurs spontaneously in animals anæsthetized with barbiturates. An inhibitory phasing theory has been offered as an explanation for the spontaneous rhythm[3]. According to this theory, a period of rhythmic activity, usually lasting 1–2 sec, is triggered off by the discharge of one cell, which, through a recurrent inhibitory pathway utilizing one or several interneurones, is producing inhibitory postsynaptic potentials in a number of neighbouring cells. When the inhibitory potentials subside, the neurones will be in a state of post-anodal exaltation, often leading to depolarization of the cell with discharges. Similar depolarizing potentials have been seen in response to hyperpolarizing pulses[4–6] or inhibitory postsynaptic potentials[7,8] in many types of neurones. In the thalamus, the post-inhibitory firing will initiate another cycle, engaging an increased number of cells, and so on, until a large proportion of the neurones in a group beat in unison. At this point, a cell, discharging prematurely, may recruit other neurones to discharge at its own rhythm, and thereby start the disruption of the dominant rhythm.

The theory has been tested by simulation of a neuronal network on a digital computer, IBM 1620. Eighty neurones were made to discharge randomly, all at a given probability of firing (PF) (Fig. 1*A*). Following the discharge of any cell, up to five other neurones were subjected to a drop of their PF to zero for 10 units of time (UT), simulating the widely distributed postsynaptic inhibitory potentials. This was immediately followed by an increase of the PF to a higher level for 2 UT, simulating the post-anodal exaltation, before the cell resumed its random PF (Fig. 1*A*). The number of neurones undergoing the change in the PF, sequential to the discharge of another cell, was not constant, but varied between 0 and 5 as shown in Fig. 1*B*. The wide distribution of the inhibitory postsynaptic potentials is due to the extensive branching of the axon of the inhibitory interneurones.

The starting of the network results in the discharge of a large number of the simulated neurones. A corresponding pattern occurs in the animal thalamus in response to an afferent volley. In Fig. 1*C*, the initial waves in the diagram indicate the synchronous and rhythmic discharges

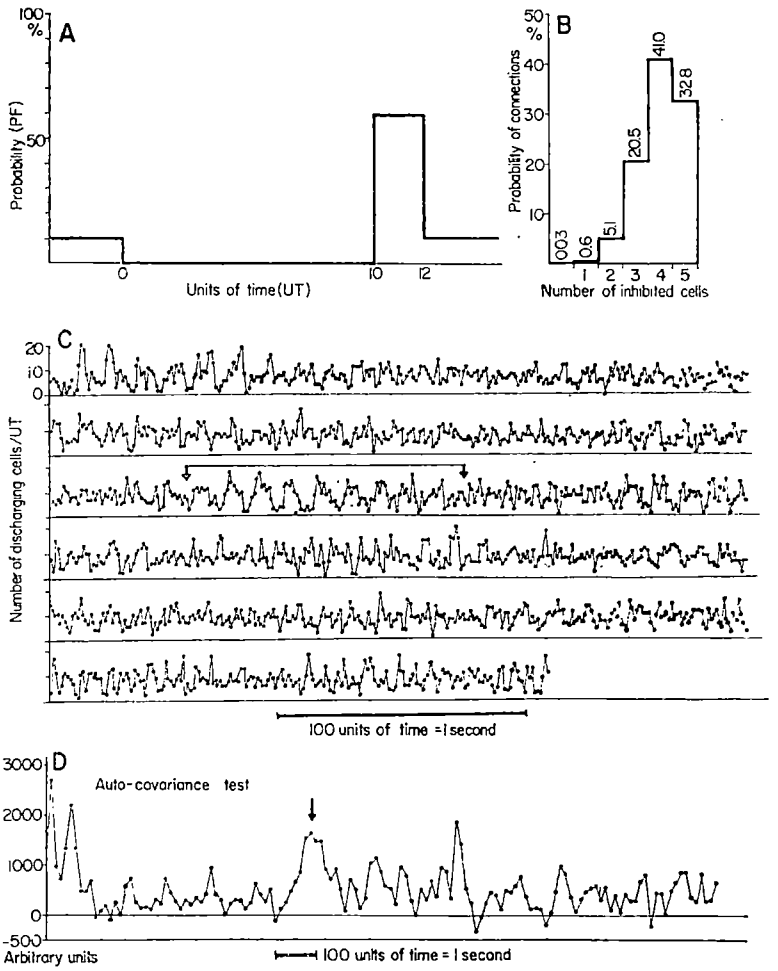

Fig. 1. *A*, The thick line indicates the change of the probability of firing of certain neurones in the model, triggered by the firing of another cell. *B*, The graph gives the probability, expressed as a percentage, of the number of neurones undergoing the probability change shown in *A*, following the discharge of a single other cell. *C*, The number of discharging neurones per unit time (UT, the scanning time of the computer) is plotted against time. The two arrows combined with a line indicate a section of marked rhythmic activity at a frequency corresponding to a period of 12 UT. The time bar below the graph indicates 100 UT, which corresponds to 1 sec in animal experiments. *D*, Auto-covariance plot of the curves in *C*, calculated as described in the text. Note the shorter time axis

of a number of cells, the appearance being similar to that observed in the cat[1,9].

Leaving the network to itself, there appear periods of rhythmic activity having a slow onset as well as offset (Fig. 1*C*, arrows). The occurrence of these periods and their shape are similar to the corresponding spontaneous activity patterns in the feline thalamus[3], and can be analysed by auto-covariance calculations. The auto-covariance is expressed as:

$$\sum_{i=j}^{j+T-1} (x_i - \bar{x}_i)\,(x_{i+\tau} - \bar{x}_{i+\tau})/n \quad \text{with} \quad j = 0, T, 2T, \ldots .$$

In Fig. 1*D*, the quantity is plotted for $T = 12$ units of time. The interval marked with arrows in Fig. 1*C* appears in Fig. 1*D* (single arrow) as a period of marked dominance of the frequency corresponding to 12 UT. The amplitude of the curve in Fig. 1*D* gives the degree of synchrony of the rhythmic waves in the network, shown in Fig. 1*C*.

Thus, the model is capable of producing activity with certain characteristics in common with the two known types of thalamic rhythmic activity. The results lend some support to the theories based on a widespread inhibition and the process of post-anodal exaltation, advanced as explanations for such activities.

Two parameters of the network turned out to be of particular importance for the production of rhythmic activity. First, the degree of the post-inhibitory increase of the firing probability, secondly, the number of neurones being inhibited subsequent to the firing of another cell. These results suggest that future animal experiments should be focused on the mechanism underlying the post-anodal exaltation, and the connexions and properties of the inhibitory interneurones in the thalamus.

Movement of the Cerebrospinal Fluid in Human Beings

Considerable controversy and doubt exist regarding the movement of the cerebrospinal fluid, and a convincing demonstration of bulk flow of this fluid is still lacking. Since obstruction of the ventricular paths invariably results in hydrocephalus, obviously a net transfer of fluid must occur from the ventricular system out into the subarachnoidal spaces. A caudad or cephalad movement of the cerebrospinal fluid in the subarachnoidal spaces, however, has been questioned[1,2].

Iodine-131 serum albumin or iodine-131 autologous cerebrospinal fluid has been injected intraventricularly and intrathecally in more than fifty patients for various diagnostic reasons[3–5]. External scintillation scans of the head are performed at various time-intervals. In this way the γ-emitter is followed in its movement through the cerebrospinal fluid pathways (Fig. 1). The labelled compound, injected intraventricularly, begins to flow into the basal cisterns within a few minutes. From the basal cisterns the activity proceeds, mainly through the anterior subarachnoid paths and the Sylvian fissures, to the convexity of the brain. At 12–24 h, most, and sometimes all, of the activity is detectable along the superior longitudinal sinus. The tracer, when injected in the lumbar area, is detected in the basal cisterns in about 1 h and from here it follows the same pattern as above. It has been calculated that 20–33 per cent of the activity injected intrathecally reaches the endocranium within 12 h. Considerable activity remains in the lumbosacral cul-de-sac even at 24 h. Positioning and the physical activities of the patient between scans do not affect the pattern of spreading. Where pathological localized blocks of the free movement of the cerebrospinal fluid occur, the radioactive material follows remaining open routes to reach the hemispheric convexities. In such instances, the radioactivity in the open pathways, and in the obstructed route proximal to the block, is in higher concentration. These data suggest a 'transport' or 'sweeping' phenomenon. Although an ebb-and-flow component may be present, there is definitely a net forward progression of the cerebrospinal fluid. Technetium 99*m* pertechnate (mol. wt. 163) injected intraventricularly in one, and intrathecally in three patients, failed to be transported with the cerebrospinal fluid but was obviously resorbed locally at the site of injection.

It is probably true that the cerebrospinal fluid is formed everywhere and resorbed everywhere in the cerebrospinal fluid cavities. It is also true, however, that at least part of this fluid moves in a flow-like fashion towards the hemispheric convexities, possibly due to the vascular[6–8]

and choroid plexus pulsations[9], plus the *vis a tergo* of the newly produced fluid.

HÆMATOLOGY

Abnormal Hæmoglobin and Glucose-6-phosphate Dehydrogenase Deficiency in Malayan Aborigines

THE aborigines in Malaya form a distinct group of the Malayan population. They live more or less separated from the other groups and are genetically as well as socially entirely different from the group at present known as Malays. They are divided racially, according to William-Hunt[1], into the Negritos, the Senoi and the aboriginal Malays. The Senoi group is the largest and consists of many different sub-groups, of which the Temiar (or Temer), Semai and Temuan are the most important. Of the aboriginal Malays, the Jakun and the Semelai are the largest sub-groups. This classification is not universally accepted, but it forms a convenient basis for further discussions. Most of the aborigines live in the jungle, where the frequency of parasitic and tropical diseases is high and where infant mortality from malaria and dysentery is high.

Recently much interest has been aroused for the investigation of the distributions of abnormal hæmoglobins and G-6-P dehydrogenase deficiency especially in association with malaria. Because of the distinct characteristics of the aborigines from the genetic point of view as well as from their way of living and their environmental challenges, it was thought to be of interest to examine the frequencies of abnormal hæmoglobins and G-6-P dehydrogenase in these aboriginal groups. Vella[2] found a high frequency of hæmoglobin E (29 per cent) in 41 Semelai examined. G-6-P dehydrogenase deficiency has not previously been reported in Malayan aborigines.

Healthy aborigines, predominantly Senoi, were obtained from the Senoi military camp in Kuala Lumpur and staff personnel of the Ulu Gombak Aborigines Hospital. The soldiers were recruited from the jungle in Central and Northern Malaya. A group of patients with miscellaneous diseases, mostly tuberculosis, were also obtained from the Ulu Gombak Aborigines Hospital, which serves aborigines from all parts of Malaya.

The dye method of Motulsky and Campbell[3], taking a clearance time of more than 120 min as abnormal, was used as a screening test. Intravenous blood was obtained from the soldiers, while blood was obtained from the finger from patients. Each positive test was repeated on an intravenous blood sample and the methæmoglobin reduction test of Brewer *et al.*[4] or the glutathione stability test of Beutler[5] or both were also performed.

Hæmoglobin analysis was carried out by the paper electrophoretic method described by Smith and Conley[6].

A total of 278 male and female aborigines were examined for abnormal hæmoglobin and 607 males examined for G-6-P dehydrogenase. The results are presented in Tables 1 and 2. Part of the result of the investigation on abnormal hæmoglobin in Malayan aborigines has been reported by Lie-Injo Luan Eng[7].

Of 154 healthy aborigines, 29·2 per cent had abnormal hæmoglobin E, while of 124 patients 25·8 per cent carried abnormal hæmoglobin E in the blood. The frequency for the total 278 examined was 27·7 per cent. The frequency for hæmoglobin E in the Semai (26·5 per cent) seems to be about as high as had been found by Vella[2] for 41 Semelai aboriginal Malays examined (29 per cent). The Temiar group, however, had a very high frequency, above 45 per cent in healthy as well as in hospital patients. It would be interesting to examine the abnormal hæmoglobins in the Negritos, the third main group of Malayan aborigines.

Of 607 persons examined for G-6-P dehydrogenase, 12·2 per cent of 197 healthy persons and 19·3 per cent of 410 patients were deficient, giving a frequency of 17·0 per cent for the total group. The frequency is, in general,

high in all aboriginal groups, but it seems to be much higher in the Senoi than in the aboriginal Malays. However, the number of each group examined was not large enough to warrant a definite conclusion. The frequency in patients is definitely higher than that in healthy persons. Whether this is due to the inclusion of patients admitted to the hospital in actual hæmolytic crisis due to G-6-P dehydrogenase deficiency or whether G-6-P dehydrogenase-deficient persons are more susceptible to certain diseases cannot be said. As we also mentioned in other papers[8], there seems to be a definite correlation between the frequencies of hæmoglobin E and those of G-6-P dehydrogenase deficiency in different areas in South-east Asia. It has been suggested from observations in other areas of the world that malaria plays a part in the causation of this correlation, due to the simultaneous protection it gives to carriers of certain abnormal hæmoglobin genes and the G-6-P dehydrogenase gene[3,9]. That malaria plays a part in the high frequency of abnormal hæmoglobin and G-6-P dehydrogenase deficiency in the aborigines in Malaya is a possibility which certainly has to be kept in mind, since indeed the infant mortality due to malaria has always been high in the aborigines. However, more detailed investigations have to be carried out before conclusions can be made, since some other factor or factors may have played a part as well. Inbreeding may be an important factor to account for the high frequencies of the aforementioned hereditary abnormalities and should certainly be investigated further.

We are grateful to the Senoi Praaq Regiment and the commanding officer, Enche Mohamed Ruslan bin Abdullah, for permission to obtain blood samples from his men, and also to Enche bin Abdullah bin Sainy, of the same unit, for his assistance. We also thank Dr. J. M. Bolton, director of the Ulu Gombak Hospital, for permission to obtain blood from the personnel and patients of the hospital.

Coenzyme Q_0 Derivative from Fibrin Clots

During my investigation of clotting and lytic factors from fibrin clots, I observed that on boiling in 1 N hydrochloric acid the clots disintegrated and consistently turned a faintly purple colour. Attempts to extract the pigment from the fibrin residue were unsuccessful. To learn more about this compound, 1 l. of normal citrated human plasma was recalcified, the fibrin digested with 1,000,000 units of crystalline bovine trypsin in distilled water at 37° C overnight, and the undigested sediment, making up about 0·5 ml., washed 3 times in saline and once in distilled water. 2 ml. of 1 N hydrochloric acid were then added, and the mixture was placed in a boiling water bath for 10 min. The change in colour of the sediment was again noted, yet following centrifugation some pigment was also seen in the supernatant. It was slightly reddish, but on neutralization with sodium hydroxide became yellow. After drying in the presence of the salt, the pigment could not be taken up in any organic solvent except methanol, and in it only partially. Since chromatographic separation proved possible, strong adsorption to solids appeared to be one of its characteristics. The partially purified pigment in distilled water gave a distinct ultra-violet spectrum, with a minimum at 250 mμ and a maximum at 265 mμ. Some pigment was liberated from digested fibrin with β-glucuronidase, but the amount found in the supernatant was much smaller than when boiling with acid was carried out.

In a previous communication[1], a menadione derivative had been reported to be present in the supernatants of digested fibrin clots, partly uncombined and partly conjugated with glucuronic acid. It thus seemed reasonable to speculate that the pigment here encountered might be derived from a cell constituent of similar chemical constitution. All cells contain ubiquinones or coenzymes Q with isoprenoid chains of various lengths in the 6-position. To prepare from them a compound analogous to the vitamin K derivative[1], only coenzyme Q_0, 2,3-methoxy-5-methyl-1,4-benzoquinone, could be used. It was dissolved in benzene and sprayed on Whatman No. 1 filter paper, where it produced a deeply yellow colour after evaporation of the solvent. The colour disappeared at a rate proportional to the saturation of the atmosphere with water vapour. Oxygen or light was not necessary for the conversion. Filter papers were extracted with hot, distilled water. Desiccation left a yellowish powder, which displayed the same solubility characteristics as the pigment from fibrin clots. Their ultra-violet spectra were identical, and also their diffusion rates on Whatman No. 1 filter paper with isobutanol, acetone and distilled water in equal proportion as solvent.

The type of transformation undergone by menadione and coenzyme Q_0 appears to be dimerization. The properties of a colourless photodimer of menadione have been described in some detail[2]. It was prepared according to instructions for comparison with the orange pigment derived from the same source[1]. The latter differed from the photodimer in being soluble in alkali and ether. However, their ultra-violet spectra appeared to be the same, and their infra-red spectra differed only in one stretch at 3·4μ, given by the orange, but not the colourless, compound—a deviation still requiring chemical interpretation. Dimerization of quinones, which consists of the formation of *cyclo*butane rings between two molecules, may be the function of an enzyme secreted by blood platelets. This could explain their dual role in blood clotting and activation of fibrinolysin[3], and perhaps also the anticoagulant effect of such compounds as dicoumarol and diphthiocol, in which two molecules of 3-methyl-4-hydroxycoumarin or phthiocol, both known to have some vitamin K activity, are bound together by a methylene bridge instead of being dimerized.

The derivative prepared from coenzyme Q_0, like the analogous menadione compound, did not affect fibrin formation or decomposition *in vitro*. Following injection into an animal, however, some of it might have been expected to be conjugated with glucuronic acid in the liver, thus inducing distinct physiological effects. White mice, weighing 20–25 g, were injected subcutaneously with 0·5 mg of pigment in 0·1 ml. of distilled water and controls with equal amounts of normal saline. They proved not to be suitable for differential fibrinolysin tests since they normally have a fairly high serum titre of this substance.

Observations made in some, but not all, animals under deep ether anæsthesia 2 h after injection of the pigment included congestion of the skin blood vessels and occasional spontaneous hæmorrhages. The only consistent finding differentiating test animals from controls was a rise in the neutrophil/lymphocyte ratio. Blood was obtained at intervals from the tail vein by cutting off a portion of the tail, which prevented healing for several hours; or blood from the tail was used only for the first sample, while the second sample was taken from the severed jugular vein of the sacrificed animal. With the first method, there was a considerable increase in neutrophils even in controls in response to the injury inflicted. Greatest changes were generally recorded 2 h after the original injection. Before injection the average neutrophil/lymphocyte ratio was 1/4. In control animals it rose to 2/3–4/5 when the first method was used and remained unchanged by the second. The respective figures in test animals were 3/1–4/1 and 2/3. Experiments with larger animals will be carried out as soon as greater amounts of coenzyme Q_9 derivative can be prepared.

Reticulo-endothelial Cells as 'Nurses' for Plasma Cells and Erythroblasts in Baboons

BABOON (*Papio anubis*) marrows were taken from either the sternum or iliac crest stained with Leishman and Giemsa and examined as thin smears. In the majority of these smears nests of plasma cells as well as early erythroblasts were seen surrounding a central reticulo-endothelial cell (Fig. 1).

The arrangements of these plasma cells around the reticulo-endothelial cell resembled the erythroblast islands around the central reticulo-endothelial cell described by Bessis[1], Bessis and Breton-Gorius[2], and Policard and Bessis[3], in their electron microscope investigations of hypersideræmic anæmias (Fig. 2).

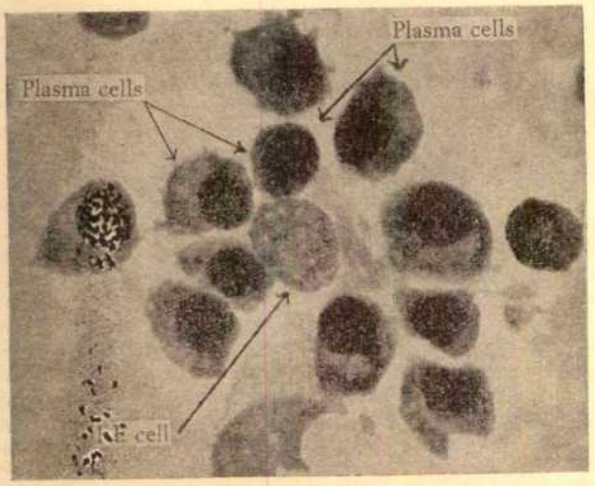

Fig. 1

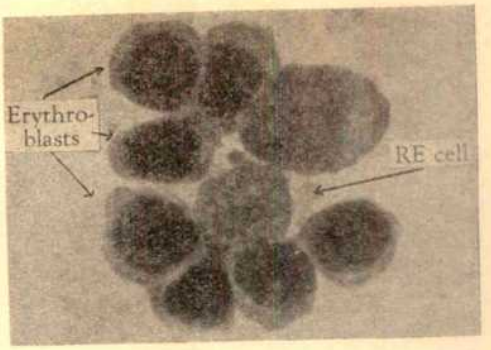

Fig. 2

Bessis *et al.* have suggested that a transfer of ferritin molecules occurs by pinocytosis across the adjacent boundary between the reticulo-endothelial cell and the erythroblasts.

If such a transfer of ferritin does occur we wonder whether any exchanges are going on between the reticulo-endothelial cells and the surrounding plasma cells described here. Plasma cells are thought to be concerned with various immunological processes, and the possibility exists that a transfer of 'immunological bodies' or their precursors may be occurring.

In some of the baboons infections such as diarrhœa, pneumonia or *Plasmodium kochi* were present. Other animals were, however, normal.

HISTOCHEMISTRY

Electron-microscopical Localization of Products from Histochemical Reactions used to detect Cholinesterase in Muscle

IN 1949 Koelle and Friedenwald[1] described a procedure to determine the sites of cholinesterase activity in tissues. Essentially, the method depends on the hydrolysis of acetylthiocholine, or similar esters, by the tissue enzyme and the formation at or near the site of enzymatic activity of a precipitate due to the combination of copper ions and the split thiocholine. Recently this and other methods have been used to determine the electron-microscopical localization of the enzyme in mammalian muscle[2–6].

In the experiments recorded here, the frog sartorius muscle, fixed in glutaraldehyde, was incubated for 20 min–7 h in a medium containing acetylthiocholine. After incubation the muscle was washed briefly and 'developed' in ammonium sulphide (cf. Couteaux and Taxi[7] for further details). Small specimens from the muscle were then further fixed in osmic acid, dehydrated in ethanol and embedded in 'Araldite'. Sections of this material were examined unstained or stained with lead citrate.

It was found that this treatment produced fine electron-dense particles (10–100 Å) which were scattered throughout the muscle fibre. A marked concentration of these particles occurred in certain parts of the endoplasmic reticulum, namely in the centre element of the triads and in some longitudinal tubules (150–200 Å wide) which run parallel to the myofibrils and seem to be connected to the central elements. Occasionally, these tubules, densely filled with

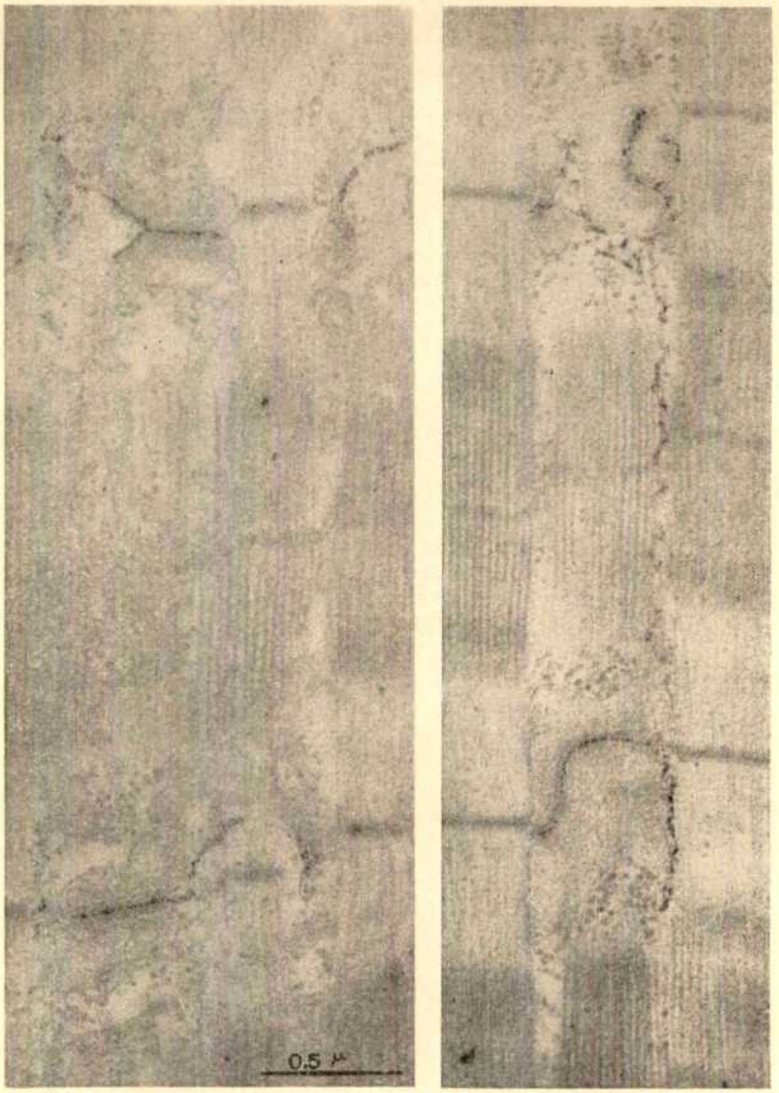

Fig. 1. Particles in the endoplasmic reticulum of two muscle fibres

the particles, can be traced throughout the whole length of a sarcomere (about 2·5μ). Dense particles can also be seen in myelin like figures and tubules which occur frequently near muscle nuclei, and occasionally in mitochondria, resembling the accumulation of metal ions described by Peachey[3].

With incubations of more than 1 h, the synaptic cleft at the nerve muscle junction was completely filled with the precipitate. Vesicles lying immediately under the muscle membrane in the synaptic and juxta-synaptic regions were also densely filled with the material. Fine particles were distributed generally inside the nerve terminal, but were specially concentrated in the synaptic vesicles. The distribution resembles that previously reported by Barrnett[5] (see also refs. 2–6). Particles were also concentrated in the basement membrane of the muscle fibre in the region surrounding the neuromuscular junction, and in the basement membrane of neighbouring muscle fibres, even though they did not contain myoneural junctions. This almost certainly indicates that there can be appreciable diffusion of the products, since no similar accumulation was seen in the basement membrane of a muscle fibre a few hundred μ away from the synaptic region. At the myotendinous junction, where cholinesterase is also concentrated[9,10], the electron-microscopical distribution of the precipitate resembles closely that at the nerve-muscle junction.

If the treatment with ammonium sulphide is omitted the Cu-thiocholine complex can be washed away i phosphate buffer (*p*H 7–7·4) and during the subsequen dehydration with ethanol. With this procedure particle which previously were seen to be diffusively distribute throughout the muscle are almost completely removed But the special accumulation in the central element o the triad and its associated longitudinal tubules is sti clearly visible (Fig. 1). This pattern resembles th distribution of ferritin particles recently described b H. E. Huxley[11].

At the neuromuscular junction, the very dense precip tate in the synaptic cleft is also removed, leaving in th gap only a few scattered particles. In the nerve ending essentially only the particles associated with synapti vesicles are left (Fig. 2). On close examination it appear as if some of the particles were stuck to the membrane, an not inside the synaptic vesicle.

One question that is raised by these findings concern the significance of the accumulation of particles i the transverse and longitudinal tubules of the triad in the muscle. Obviously, this could mean that these ar actual sites of cholinesterase activity, which would accoun at least partly for the cholinesterase activity found i muscle fibres away from the myoneural junction[12,1] But, in view of the demonstrable diffusibility of th precipitate, it remains still possible that the acetylthio

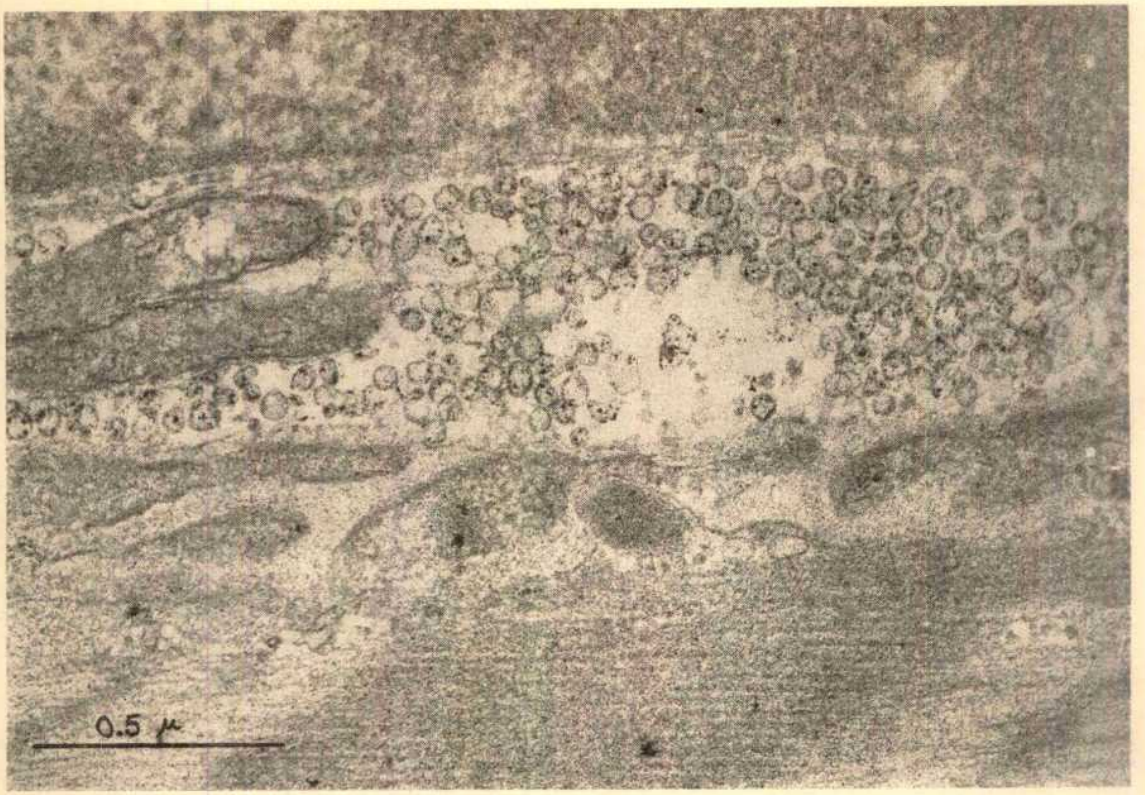

Fig. 2. Neuromuscular junction. Muscle fibre below, axon at centre and Schwann cell nucleus at top of picture. Notice the particles in the synaptic vesicles inside the axon

choline is split somewhere else within the muscle, for example by myosincholinesterase[14], and that the products are secondarily retained by the endoplasmic reticulum. Similar alternatives could explain the presence of particles in the synaptic vesicles.

I thank Miss J. Bott for her assistance.

Histochemical Evidence on Localization of Succinic Dehydrogenase in the Synapse of the Central Nervous System of Rabbit, Rat, and Guinea-pig

Succinic dehydrogenase activity of the normal spinal motor neurone was demonstrated as spotted in type at the cell membrane of the motor neurone in the spinal cord[1] of the guinea-pig.

This communication describes the localization of succinic dehydrogenase activity on the surface of various types of neurones in the medulla oblongata, pons, mesencephalon, cerebellum and cerebral cortex of the adult rabbit, guinea-pig and rat. The same staining procedure as that of a previous investigation was used[1].

The spotted succinic dehydrogenase reaction, which appears at the outer surface of the cell bodies, was demonstrated in the multipolar cells of the reticular formation (Figs. 1 and 2), the nerve cells of the motor nucleus of the trigeminal nerve and the cells of origin of the motor fibres of the oculomotor nerves. In addition, the cytoplasmic succinic dehydrogenase activity in these cells showed a homogeneous, moderately positive reaction.

All animals showed less spotted enzyme activity at the surface of cell bodies of the superior olivary nucleus (Fig. 3), the inferior colliculus (Fig. 4) and the mesencephalic nucleus of the trigeminal nerve (Fig. 5).

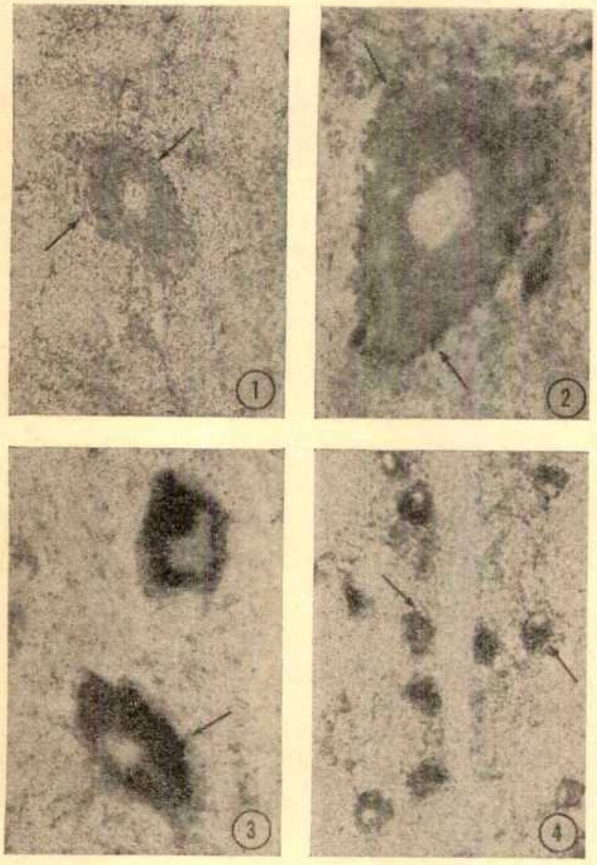
This was especially true in the mesencephalic nucleus of the trigeminal nerve and the cerebral cortex in which it was not possible to visualize the spotted succinic dehydrogenase activity at the outer surface of the cell bodies at all.

According to Smythies *et al.*[2], the boutons in the cerebral cortex do not resemble those in the spinal cord and are not closely applied to the surface of the cell body.

Succinic dehydrogenase activity was strong to moderately positive in the neurophil of the cerebral cortex and in the intracellular space which includes the neuroglia. Histochemical demonstration of spotted succinic dehydrogenase activity at the walls of the cell bodies in the cerebral cortex was indistinct.

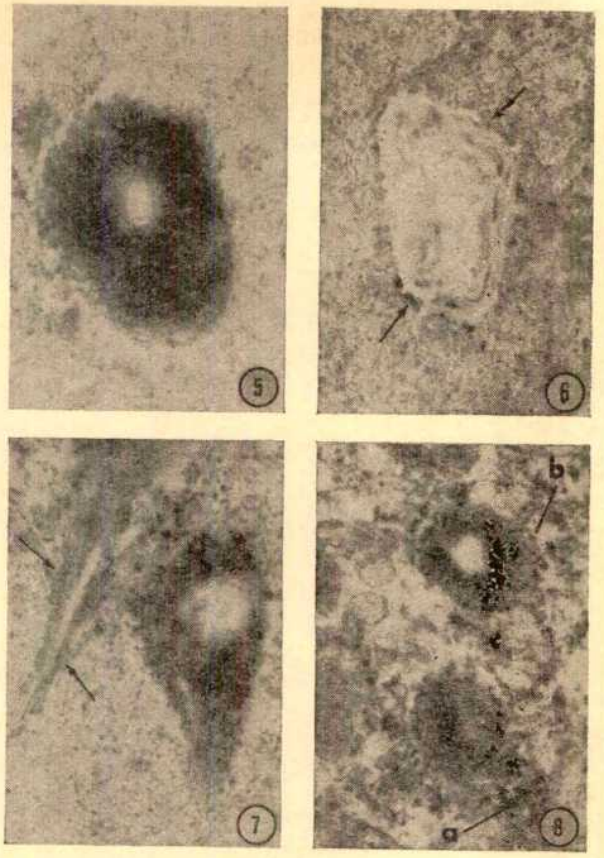
The localization of succinic dehydrogenase activity on the walls of the nerve cell body was accompanied by a similar localization at the walls of blood capillaries in the brain. As shown in Figs. 6 and 7, the spotted enzyme activity was arranged along the walls of blood vessels and at axon surfaces. These findings also occurred in the medulla oblongata, pons and mesencephalon in all animals. The localization of succinic dehydrogenase in the Purkinje layer of the cerebellum was variable (Fig. 8). The spotted succinic dehydrogenase activity of the Purkinje layer in the cerebellar cortex differs from that of the medulla

oblongata, pons, etc. The spotted positive reaction for succinic dehydrogenase showed a variable pattern as well as aggregates in the intracellular space in the Purkinje layer, surrounding the cell body, and in the nearby granular layer. From a histochemical point of view, the foregoing shows spotted localization of succinic dehydrogenase. This is associated with the synapses of Purkinje cells as seen with silver impregnation, as well as the network or basket formation from the basket cells (cf. ref. 3).



In electron-microscope observations on the synapse, the bouton terminaux or end-feet were shown to contain numerous mitochondria[4–8].

The spotted succinic dehydrogenase activity at the walls of the nerve cell bodies probably demonstrates the enzyme activity of synaptic mitochondria.



Friede[9] demonstrated spotted succinic dehydrogenase activity of the cell membrane in chromatolytic cells in the nuclei of origin of the vestibulospinal and reticulospinal fibres. Our observations were interesting in showing that succinic dehydrogenase activity in neurones was located at the membranes of the cell bodies and their axons and in the walls of blood capillaries in the normal brain.

Glycogen and other polysaccharides can also be found at the membranes of the nerve cell[10–12].

The higher levels of spotty synaptic succinic dehydrogenase activity seem obviously to be correlated with glycolysis of synaptic glycogen and thus play a part in the energy changes concerned with impulse transmission.

Figs. 1–4. 1, Succinic dehydrogenase activity in a multipolar cell of the reticular formation of rabbit. Note spotty reaction (arrows) on outer surface of cell. Cytoplasmic reaction is moderately positive (× *c.* 170). 2, Succinic dehydrogenase activity in multipolar cell of reticular formation of guinea-pig. Note numerous spotty positive areas (arrows) on outer surface of cell body (× *c.* 660). 3, Succinic dehydrogenase activity of the cells in the superior olivary nucleus of guinea-pig. Note strong positive reaction in the cytoplasm and spotty succinic dehydrogenase activity on outer surface (arrow) (× *c.* 660). 4, Succinic dehydrogenase activity of the small cells of the nucleus of the oculomotor nerve of rabbit. Note strong positive reaction in cytoplasm and spotty activity on outer surface of cells (arrows) (× *c.* 100)

Figs. 5–8. 5, Succinic dehydrogenase activity in the cell of the mesencephalic nucleus of the trigeminal nerve of rat. Note strong positive reaction in the cytoplasm and much fainter reaction on the outer surface of the cell body (× *c.* 660). 6, Succinic dehydrogenase activity on the walls of blood vessel in the medulla oblongata of rat. Note spotty positive areas on wall (arrows) (× *c.* 660). 7, Succinic dehydrogenase activity at the surface of axon and cell body in pons of guinea-pig. Note spotted positive reaction along the axon and surface of cell body (arrows) (× *c.* 660). 8, Succinic dehydrogenase activity in the Purkinje layer in cerebellum of guinea-pig. Note spotty reaction for the enzyme. The spots are aggregated in the intracellular space (*a*) and surround the cell body (*b*) (× *c.* 660)

BIOLOGY

Structural and Enzymatic Changes in Muscle due to Ageing

So far, there has been no systematic and detailed investigation on the enzymes and their changes with ageing. The activity of various enzymes was found to change with ageing in different ways[1]. No change occurs

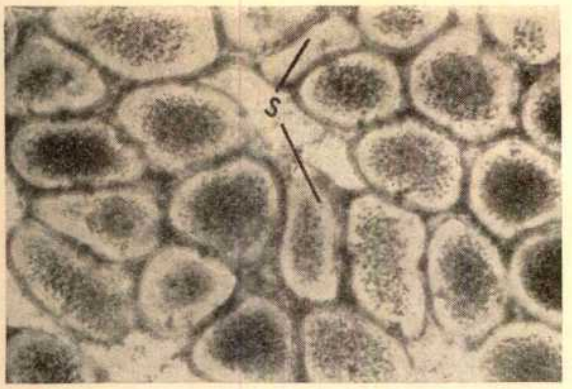

Fig. 1. Photomicrograph of the cross-section of the fibres of the human spinal muscle, showing the localization of lipase activity. Note the high degree of variation in the shape of the fibres. The compressed fibres with negligible enzymatic activity are also seen (*S*)

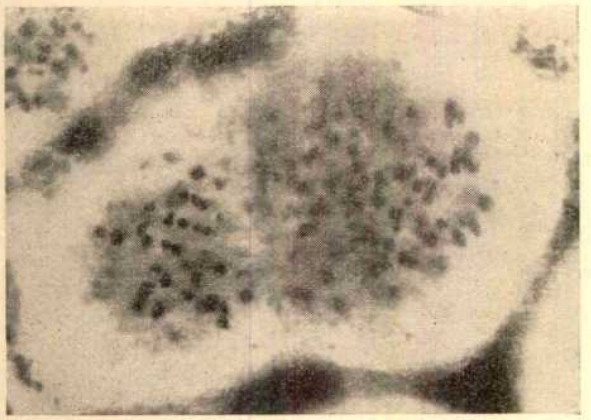

Fig. 2. A single fibre enlarged. Note the outer margin encircling the central active zone

in certain tissues, while in others the activity increases or decreases with ageing. A detailed investigation was therefore designed on the cellular and enzymatic changes in the human muscle.

The human spinal muscle of an individual 47 years old was the material for the investigation recorded here. The lipid-hydrolysing enzyme was localized histochemically[2] in the fibres.

The lipase activity is localized as brownish black precipitates of lead sulphide in the fibres (Fig. 1). The enzymatic activity is localized more or less uniformly except for a few fibres where the activity is negligible. A high degree of variation in the shape of the fibres has also been observed. The enzymatic activity is mainly restricted towards the centre of each of the component fibres, leaving an outer margin (Fig. 2). The outer margin with negligible enzymatic activity is nothing but the thickening or the condensation of the endomysium. The endomysial connective tissue sheath encroaches more and more, thus diminishing the active sarcoplasm—a feature which becomes prominent during ageing.

The fibres with negligible enzymatic activity are few in number, much compressed and shrunken in nature. These fibres are not a common appearance in the normal developing muscle or in fully grown and mature muscle. However, the changes in the fibre nature and the enzymatic activity in no circumstance can be due to defects in fixation. If it were due to any neuromuscular disorder, fibre degeneration would occur; but the degenerating fibres are never found singly. A cluster of fibres or the fibres of a fasciculi become affected. Since the pattern of degeneration is altogether different in the present investigation, the possibility of a neuromuscular disorder is also ruled out.

The negligible enzymatic activity in these compressed fibres indicates the inefficiency of esterifying and utilizing fat for energy. The compressed fibres with decreasing and depleting enzymatic activity are the degenerating fibres due to advancing age. Disturbances in energy metabolism as an initial phenomenon in ageing have been reported[3]. The ability of the muscle fibre to divide during old age for the replacement of the degenerated and perished cells was also observed in the present investigation[4]. The structural and enzymatic changes that have been observed in the present attempt are, therefore, considered to be the effect of ageing on muscle fibres.

Identification of a Kinetin-like Substance from Pea Seedlings, *Pisum sativum*

The importance of kinetin and related compounds in controlling different physiological processes in higher plants has been widely recognized, although attempts to isolate and identify such substances in plant material have so far failed[1]. Chromatographic separation of pea seedling extract yielded some pertinent information which is reported here.

English peas, variety 'Laxton's Progress', were grown in a flat of sterilized soil for 17 days before they were harvested. Four thousand plants were included in each extraction and the whole experiment was repeated twice. The plants were gathered and divided into three parts (top, middle and bottom). The plant parts were cut into small pieces and were then homogenized in a Virtis apparatus for 10 min with 10 per cent hydrochloric acid. The homogenate was filtered under a high vacuum pump and concentrated in a Rinco evaporator. The solid evaporated samples thus obtained were dissolved with 10 ml. of distilled water. The crude extracts were then separated by means of descending chromatography using a solvent system consisting of iso-propanol, distilled water, and concentrated hydrochloric acid (130 : 37 : 33). Known concentrations of kinetin (obtained from California Biochemical Research) and adenine (100 p.p.m.) were used as controls, along with the unknowns for identification. The R_F values were determined by developing the paper with location reagent consisting of 2 per cent silver nitrate and 0·4 per cent bromophenol blue (v/v). The blue-coloured spots thus obtained were eluted with 10 ml. of absolute ethyl alcohol and the concentrations of the eluted samples were determined by colorimetric tests using a Coleman Junior Spectrophotometer at a wave-length of 650 mμ, with known concentration of kinetin as the standard. A bioassay test was attempted with *Raphanus sativus* leaf disk[2], but it was not successful.

The plant extract from the top parts gave a comparable spot on the chromatogram which had the same R_F value as kinetin (0·88). Two more spots were developed which occupied the same region as adenine in the control. However, the kinetin spot was not clear in extracts of middle and bottom parts, although in these there was a faint suggestion of its presence in the extract from the middle portions. All three were eluted in alcohol and the concentration was determined as described earlier. The results obtained are presented in Table 1.

The top portion gave a 3–5 p.p.m. concentration of kinetin-like substances, whereas the middle portion gave less than 1·0 p.p.m. and the bottom none. This suggests that the presence of kinetin-like substances may be restricted to growing regions only.

Table 1. Concentrations of Kinetin-like Substances (p.p.m.) in Pea Seedlings as Determined by Colorimetric Tests*

	Kinetin-like substances in Top portions	Middle portions	Bottom portions
English pea, variety 'Laxton's Progress'	3·0–5·0	Less than 1·0	None

* Results include both replications.

This work gives some indication as to the presence of kinetin-like substances in higher plants. It is found that these substances are mainly present in the top portions of the plants. However, the chemical identification requires an elaborate investigation.

I thank Prof. B. C. Pal of this Institute for his advice.

Effect of the Implantation Site on the Development of Grafted Limb Bud Mesoderm in Chick Embryos

A small rectangular block of the mesoderm immediately subjacent to the superficial venous plexus was excised from the wing bud apex in stages 25–26 of chick embryos and replaced with an isolate of mesoderm from the prospective thigh or proximal foreleg region. The graft extended from the dorsal to the ventral surface of the wing bud apex and did not lie in contact with the apical ridge of the ectoderm; it was separated from the latter structure by the mesoderm intervening between the apical ectoderm and the superficial venous plexus, namely, by about 15–20 layers of mesodermal cells of the wing bud (histological control).

Embryos at stages 25–26 only were used for the two following reasons: (*a*) according to the supporters of the thesis of a return inductor activity exerted by the apical ridge, the distal territories of the limb would be "capable of differentiation independently of the influence of the apical ectoderm" by stage 24 (ref. 2); (*b*) the graft inserted at the limb bud apex at stages 25–26 maintains its distal position and is not displaced to more proximal regions in consequence of the distal growth of the bud as occurs when younger stages are used.

In the majority of the operated embryos the more or less complete skeleton of one or two toes and 1–3 fingers of the hand formed in the terminal part of the wing. The toes are covered distally with scales associated with feathers and end with a claw (Fig. 1). The mentioned result is not related to any special orientation of the axes of the grafted material in respect to the axes of the host wing bud. The terminal foot structures in the wing seem to develop from the grafted proximal material of the hind-limb bud; however, the possibility that mesenchymal cells from the wing area surrounding the graft may invade the latter and take part in the development of the foot rays cannot be ruled out at present.

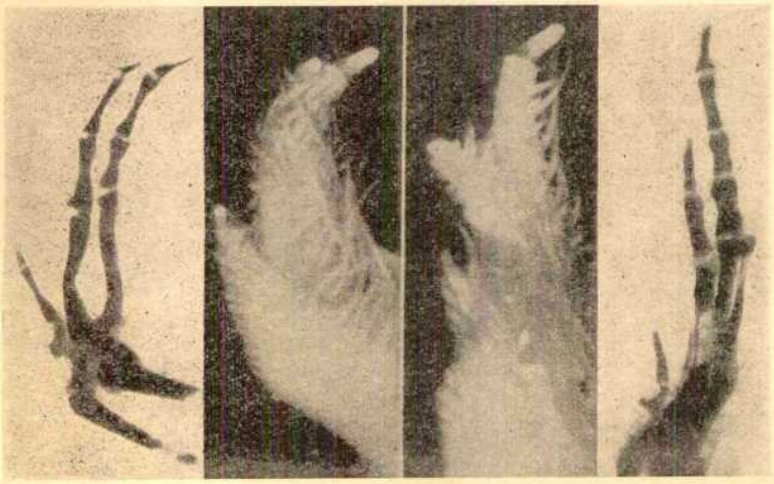

Fig. 1. Embryos of 13 days operated at stage 25–25·5. Notice the phalanges and the claw of the toes developed on the host wing

These experiments and their result bear a close resemblance to those of Saunders *et al.*[1–3], who grafted a small block of prospective thigh mesoderm subjacent to the apical ectodermal ridge of the wing bud in stages 18–23 of chick embryos. Grafts which remained in contact with the apical ectoderm frequently formed typical foot parts terminally on the wing; grafts separated from the apical ridge through interposition of wing mesoderm developed at wing levels proximal to the wrist and did not form toes. According to the authors mentioned, the return inductor activity of the apical ridge of the wing bud affected the regional character of morphological differentiation of the grafted thigh mesoderm and not its specific leg quality.

Our experiment indicates that changes of the regional character of morphological differentiation of prospective thigh or proximal foreleg material grafted to the wing bud apex may take place in stages 25–26 embryos independent of a contact of the grafted mesoderm with the apical ridge of ectoderm. The change in the developmental fate of the grafted hind-limb mesoderm could be related to organogenetic influences exerted by the mesenchymal territories of the wing apex directly on the material of the graft.

ENTOMOLOGY

Occurrence of Microvilli and Micropinocytosis in Trophocyte of *Bombus*

Recent investigations have suggested that micropinocytosis plays an important part in the formation of egg yolk in insects. Roth and Porter[1] have recently described the occurrence of this process at the periphery of developing oocytes in the mosquito. Anderson[2] has observed a similar process in the oocyte of *Periplaneta*. It has been described in the small milkweed bug *Lygaeus kalmii* by Kessel and Beams[3]. The last-named workers suggest that micropinocytosis plays an important part in the formation of some yolk constituent, but it is questionable whether it is responsible for all yolk production.

Individual follicles of *Bombus* trophocytes were fixed in 1 per cent solution of osmium tetroxide at 0° C buffered with phosphate to *p*H 7–8 for 1·5 h. Following rapid dehydration in a series of cold ethanols the tissue was embedded in 'Araldite'. Sections were obtained with grey interference colours, using the Huxley microtome, and mounted on untreated grids. The sections were stained for 5 min with lead citrate[4] before being examined in an *EM6* electron microscope. Micropinocytosis occurs at the periphery of the developing oocytes of *Bombus*, where it appears to fulfil a similar role to that suggested above. At the stage of development when microvilli appear at the periphery

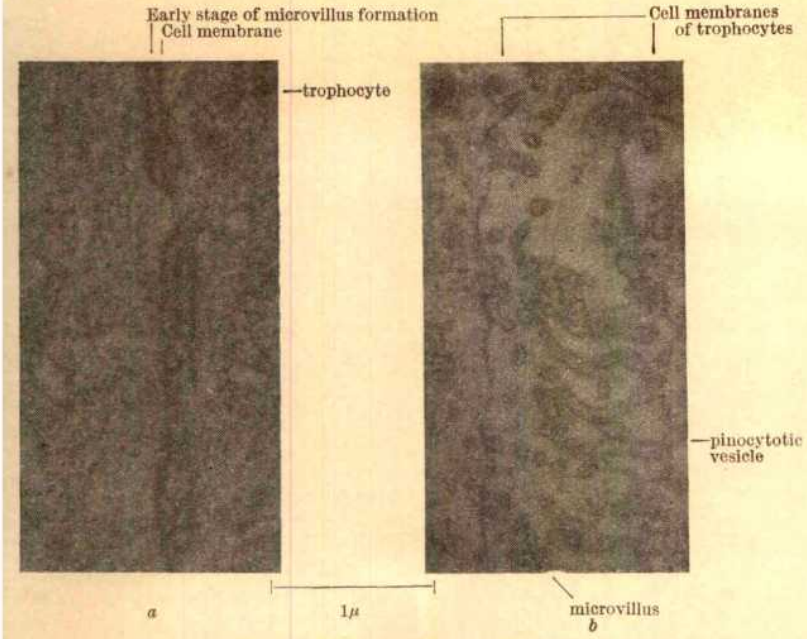

Fig. 1. Electron-micrographs of trophocyte membranes in *Bombus*

of follicle cells and micropinocytosis occurs at the periphery of the oocyte areas of the cell, membranes of the trophocytes (Fig. 1*a*) also form microvilli where they are in contact with other trophocytes or trophocyte follicular epithelium. These microvilli grow as development continues and project into spaces between the trophocytes which are formed by the cell membranes of adjacent trophocyte no longer being in contact (Fig. 1*b*). This may give a network of spaces between the trophocytes, allowing substances to be passed to them or removed from them. In the later stages of yolk synthesis micropinocytosis occurs in the pits between the microvilli. It is possible that processes occurring in these regions bear some similarity to those in the oocyte.

Effect of Two Chemosterilants on *Glossina morsitans*

The use of sterile males offers a theoretical advantage over the use of insecticides in insect control[1]. This advantage is greater in the control of low-density pest species such as the screw-worm[2]. The sterile male technique has therefore been suggested for the control of tsetse flies, and Potts[3] examined the effects of γ-radiation on tsetse fly pupæ. Some exploratory work has now been done on the effects of two chemosterilants, 'Apholate' (2,2,4,4,6,6-hexahydro-2,2,4,4,6,6-hexa-*cis* (1-aziridinyl)-1,3,5,2,4,6-triazatriphosphorine) and 'Metepa' (*tris*(1-(2-methyl)aziridinyl) phosphine oxide) on *Glossina morsitans*.

Wild pupæ were collected in the bush at Singida and taken to Arusha, where the adult flies were allowed to emerge in a room heated to 27° by day and allowed to cool to 19° overnight. On emergence the flies were dosed topically with 0·5 μg of chemosterilant dissolved in 0·5 μl. of methyl-ethyl-ketone. After treatment the flies were kept in a room at 27° and fed on sheep every three days. Female flies were mated three days after emergence and male flies after eight days[4]. Treated flies were mated once with treated or untreated flies. Any pupæ resulting were kept to breed out a second generation.

In Table 1 are given the mean numbers of pupæ produced in each treatment by those female flies which lived more than 20 days and therefore had the opportunity of producing pupæ. It is noteworthy that treating the males caused a reduction of only some 40 per cent in the mean number of pupæ produced by the untreated females. Mating treated females with treated or untreated males produced no pupæ with 'Apholate' and very few with 'Metepa'.

Treating only the female flies with 'Apholate' shortened their mean life to 16·6 days and with 'Metepa' to 15·8 days. Untreated control females had a mean life of 34 days. The shortening effect was more marked when the treated females were mated with treated males, the mean female life using 'Apholate' being 8·8 days and with 'Metepa' 5·3 days. However, it is surprising to find that untreated females mated with treated males lived longer than the 34 days of the control group, 52 days using 'Apholate' and 46 using 'Metepa'. The mean life of males treated with 'Apholate' was 12·5 days, with 'Metepa' 13·1 days, and the life of the control-group males was 17·2 days.

Figures are given in Table 2 relating to the pupæ and adult flies produced by parents treated with chemosterilant. The numbers involved are small and the figures correspondingly unreliable. It would seem, however, that the percentage emergence was low when the male parent was treated with 'Metepa', the effect being less marked with 'Apholate'.

The action of the two chemosterilants on the pupæ was also examined. Wild pupæ were dosed on arrival with 0·1 μg of chemosterilant, placed in boxes and the flies allowed to emerge in the normal way. Of 95 pupæ dosed with 'Apholate', only 42 per cent emerged and all the flies were dead within a week. 79 per cent of a batch of 100 pupæ dosed with 'Metepa' emerged compared with 72 per cent among the controls. The male flies in the 'Metepa' group had a mean life of 7·7 days and the females 12·9 days. The corresponding life-times for control groups were 17 and 34 days.

Table 1. Pupæ produced from matings of flies treated with 0·5 μg doses of chemosterilant applied topically

Treatment	Mating	No. of females	% of females living over 20 days	No. of pupæ	Mean pupæ per female over 20 days	No. of visible abortions per female over 20 days
'Metepa'	♂ × S♀	85	19	8	0·5	0·37
'Metepa'	S♂ × ♀	12	67	14	1·75	0
'Metepa'	S♂ × S♀	78	6	3	0·6	0
'Apholate'	♂ × S♀	27	22	0	0	0
'Apholate'	S♂ × ♀	52	73	56	1·47	0·03
'Apholate'	S♂ × S♀	46	0	0	0	0
Control (undosed)	♂ × ♀	245	38	254	2·76	0·26

(S♂ or S♀ = treated fly)

Table 2. Pupæ and adult flies from parents treated with chemosterilants

Treatment	Mating of parents	No. of pupæ	Mean pupal weight (mg)	% emergence	Mean life of flies (days)
'Metepa'	S♂ × ♀	14	19·7	27	2·6
'Apholate'	S♂ × ♀	56	21·0	48	4·5
'Metepa'	S♂ × S♀	3	19·5	100	0·7
'Metepa'	♂ × S♀	8	19·9	63	4·2
Control	♂ × ♀	150	20·6	72	5·6

Two of the females from the 'Metepa'-treated pupæ lived long enough to produce pupæ of their own after mating with untreated males. One of these produced two pupæ and the second none. The surviving males were mated with untreated females, but only two lived long enough to produce pupæ, although neither did so in fact.

These exploratory experiments strongly suggest that these two chemosterilants applied topically are not likely to be useful in the practical control of tsetse flies. The treatment of pupæ, produced by a breeding colony or collected in the field, is unlikely to be effective because of the low percentage emergence when 'Apholate' is used, while with either chemosterilant the flies have a shorter life than normal. The consequences of shorter life among treated flies, even if perfectly sterilized, have been examined by Simpson[5].

Treatment of the adult males followed by their release in the bush is equivalent to the matings $\delta\delta \times \varphi$, which have been found to give only some 40 per cent reduction in fertility coupled with a shortening of the life of the flies. Furthermore, multiple mating of the females is possible in the field[6]. In consequence, these two compounds are unlikely to be suitable for field use in this way. Treatment of the resting sites of the flies in the bush would result in the sterilization of the females as well, so giving a greater effect. However, this presupposes an adequate residual life for the film of chemosterilant and disregards their possible toxicity to mammals or the ecological side-effects of their widespread use.

Metabolism of Nicotine by Tobacco-feeding Insects

Recent experiments in this laboratory have indicated that the green peach aphid, *Myzus persicae* (Sulz.), avoids the nicotine in tobacco plants by selective feeding in the phloem[1], whereas the tobacco hornworm, *Protoparce sexta* (Johan.), excretes nicotine and other ingested alkaloids before a toxic dose can accumulate[2]. The present communication presents evidence that in addition to the foregoing mechanisms, insects feeding on tobacco may metabolize nicotine to other alkaloids. Such pathways have been previously reported from insects[3] that do not feed on tobacco and from mammals[4,5]. Comparative experiments on an insect which does not feed on tobacco, the house fly (*Musca domestica* L.), are also included.

Actively feeding, immature stages of the tobacco budworm, *Heliothis virescens* (F.), the cabbage looper, *Trichoplusia ni* (Hubner), the tobacco wireworm, *Conoderus vespertinus* (F.), and nymphs of the differential grasshopper, *Melanoplus differentialis* (Thom.), were collected on flue-cured tobacco, *Nicotiana tobacum* L., and brought into the laboratory. The insects were fed on alternate host plants for two days to prevent interference of ingested alkaloids in later chemical analysis. In each of five replicated experiments, ten larvæ were treated on the dorsum of the thorax with 200 μg of free base nicotine in 1 μl. of acetone. The larvæ were held for ten hours, killed, and placed in acidified methanol. Similar experiments were conducted with 100 cigarette beetle larvæ, *Lasioderma serricorne* (F.), which were treated with 10 μg of nicotine, and 500 2-day-old adult house flies which were treated with 5 μg of nicotine and held for 18 h.

The insects and their fæces were separated and homogenized in 25–100 ml. of acidified methanol. Nicotine and related metabolites were extracted using methods previously reported[2]. Aliquots of the final chloroform extracts were chromatographed on paper using a *tert.*-amyl alcohol solvent system[6]. The alkaloids were located by the cyanogen bromide method[6] and corresponding areas of untreated chromatograms were eluted with hydrochloric acid, filtered, and subjected to ultra-violet spectroscopy on a Beckman *DK*-2 recording spectrophotometer. No alkaloids were apparent in untreated insects subjected to identical conditions of extraction, chromatography, and spectroscopy.

The results in the experiment with budworms and cabbage loopers showed no apparent metabolism of nicotine. The only alkaloid detected had an R_F (0·19) and ultra-violet maximum (259 mμ) corresponding to nicotine. As previously reported with tobacco hornworms[3], larvæ exhibited no symptoms of nicotine poisoning. In addition, when budworms and loopers were fed on tobacco, the four alkaloids apparent in the fæces corresponded chromatographically and spectroscopically to the alkaloids in the tobacco plant.

The tobacco wireworm, cigarette beetle, differential grasshopper and house fly metabolized nicotine to 1, 2, 4, and 3 other alkaloids respectively (Table 1). In all cases at least 70 per cent of the alkaloids recovered were metabolites, the principal one corresponding chromatographically to cotinine. When grasshopper nymphs were fed on tobacco the fæces contained three alkaloids not detected in the tobacco plant. The principal metabolite again corresponded to cotinine.

Table 1. Metabolism of Nicotine by Certain Insects

These data are reported from experiments using the *t*-amyl alcohol system. Results with the butanol–ethanol–ammonium solvent system showed no significant difference. The quantities of alkaloids were estimated from the ultra-violet absorption maxima. The loss of topically applied free base nicotine from the surface of insects is frequently as high as 50 per cent due to volatilization. Recoveries of injected doses normally exceed 90 per cent

Insect	Alkaloids recovered R_F	Alkaloids recovered μg	% recovered alkaloids	% recovery
Tobacco wireworm	0·18	201	29·3	
	0·82	485	70·7	69
Cigarette beetle	0·18	90	22·5	
	0·82	290	72·5	
	0·89	20	5·0	80
Differential grasshopper	0·18	86	17·8	
	0·24	10	2·0	
	0·29	10	2·0	
	0·82	340	70·0	
	0·89	40	8·2	49
House fly	0·13	26	4·5	
	0·18	69	12·1	
	0·24	24	4·2	
	0·82	453	79·2	46
Nicotine	0·18	—	—	—
Cotinine	0·82	—	—	—

In contrast to the tobacco-feeding insects, nicotine and its metabolites were not readily excreted in the house fly, more than 90 per cent of the administered dose remaining in the insect after 18 h.

The principal metabolite from the grasshopper and the house fly corresponded to and co-chromatographed with cotinine in two solvent systems, *tert.*-amyl alcohol and butanol–ethanol–ammonium. This metabolite was further characterized by ultra-violet and infra-red spectroscopy. The ultra-violet maxima and minima corresponded closely to a known cotinine sample and agreed with data from a recent study on the metabolism of nicotine in the dog[6]. Fig. 1 shows that the infra-red spectrum of the isolated grasshopper metabolite corresponds to the known cotinine sample. The spectrum of the house fly metabolite also corresponds to cotinine, although the 3μ region is not distinct. As cotinine is hygroscopic it seems probable that interference due to water occurred.

The results of this investigation show that, in addition to the tobacco hornworm, two other lepidopterous insects

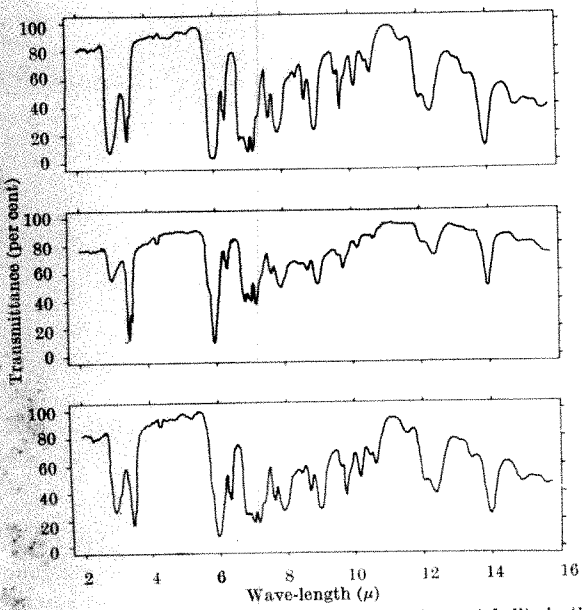

Fig. 1. The infra-red spectra of the major nicotine metabolite in the differential grasshopper and house fly. Top, cotinine; centre, *Musca* metabolite; bottom, *Melanoplus* metabolite

which have become adapted to tobacco as a host plant do not metabolize nicotine but have an efficient excretory mechanism. The coleopterous and orthopterous pests of tobacco examined were shown to metabolize nicotine to cotinine and other alkaloids. As cotinine has previously been shown to be non-toxic to insects[2], it is suggested that metabolism to cotinine represents an additional detoxification mechanism in tobacco-feeding insects. The metabolism of nicotine to cotinine may be widespread, since it occurs among mammals[4,5] and insects, although some insects, including some tobacco-feeding insects, cannot carry out this reaction. If this mechanism is important in the adaptation of insects to plants containing nicotine, its importance lies in the extent to which it occurs rather than the presence or absence of the necessary enzymes.

PSYCHOLOGY

Retention as a Function of Previous Learning

It has been argued by Underwood[1] that proactive inhibition is a major factor determining retention. On the basis of data from a large number of earlier experiments he suggests that the recall of verbal tasks is a function of the number of previously learned similar tasks: the greater their number, the lower is the recall score after 24 h. This loss of retention is assumed to reflect interference from the earlier tasks (proactive inhibition).

There is, however, an alternative interpretation of the results discussed by Underwood. When a subject learns several similar tasks in succession, the number of trials required to reach a given learning criterion decreases gradually (positive transfer), and the average number of correct (reinforced) repetitions per item decreases correspondingly. If we assume that recall of verbal list items is a function of the number of (reinforced) repetitions, we would thus expect results similar to those discussed by Underwood even if there were no interference from previously learned items. This interpretation receives support from the following type of results. When subjects learn one list a day for several successive days, there is a high positive correlation between trials to criterion and percentage recall after 24 h (for example, Warr[2]). Warr has further shown that probability of recall of verbal items is directly dependent on the number of correct anticipations of those items during learning.

In the present experiment an attempt was made to devise a situation in which trials to criterion and average number of correct anticipations of the items were constant for a given task T independently of the number of previously learned similar tasks. Evidence for proactive inhibition in such a situation could not be given the alternative interpretation discussed here, but would support Underwood's conclusions. The design of the experiment was based on the following consideration: the cumulative transfer usually found when several similar tasks are learned in succession is mainly due to learning of efficient techniques and methods of learning, to emotional adjustment, etc. ('general transfer'). Proactive interference effects, on the other hand, should be primarily related to the contents of the tasks. Consequently, sufficient pre-training in the use of a specific method, with one type of content, should secure that little or no additional transfer occurs when tasks with a different type of content are learned afterwards by the same method.

Thirty-six subjects—mainly firemen, who had ample time for the task—were given 4·5 h pre-training in the use of the paired associate method of learning. Ten lists were used: seven lists with numbers, two word lists, and one list with figures. In the experiment proper, nine lists of paired nonsense syllables of equal and low association value were used, one of these being the critical list T. The subjects were divided into four groups. Group I learned only T, Group II learned two other lists and T, Group III learned five other lists and T (three lists a day), and Group IV learned eight other lists and T. All lists were learned to the criterion of a single correct trial. The last-learned list, T, was recalled after 24 h.

Table 1. Loss of Retention due to Proactive Inhibition

Group	No. previous similar tasks	Mean trials to criterion, list T	Percentage recall of T after 24 h
I	0	13·7	61
II	2	9·6	55
III	5	13·6	48
IV	8	12·1	39

The main results are presented in Table 1. The average number of trials required to learn T was approximately equal in all groups ($F = 1{\cdot}83$). No statistically significant transfer effects occurred in the learning of syllable lists in any group. In the recall scores, on the other hand, there were clear-cut differences between the groups: the score was lower the greater the number of previously learned syllable lists. An analysis of variance of the recall scores yields an $F = 13{\cdot}2$ ($P < 0{\cdot}001$). It may be pointed out that to the extent that pre-training experiences affect the recall scores (by giving rise to additional proactive interference) they should tend to decrease the differential effects of the learning of syllable lists on the recall of T. A control group, learning list T without any preceding pre-training, required on the average 16·9 trials to reach the criterion, and recalled 69 per cent of

the items after 24 h. The differences between the recall scores of Groups I–IV thus appear to be primarily due to proactive interference.

The correlation between speed of learning and recall of T was negative but low. However, there were indications in the results of a positive correlation between the number of reinforced repetitions and the probability of recall of individual items, supporting Warr's findings.

The results yield clear-cut evidence for the assumption that proactive inhibition is a factor determining retention, although the effects were smaller than might be expected from Underwood's curve. At the same time the results are consistent with the argument that part of the differences in retention interpreted by Underwood in terms of proactive inhibition may simply reflect differences in degree of learning of the items.

Illusory Perception as a Constancy Phenomenon

Gregory[1] offers a general account of visual illusions, relating the apparent distortions in them to the perceptual process of size constancy. He observes that Tausch is the only previous writer to have considered constancy in relation to illusions. However, Gibson[2] has incorporated illusory perceptions within the context of size constancy, and suggests that perception of size is a by-product of a constant scale, which Gregory calls 'constancy scaling', at different distances. Arguing that illusory figures are "flat projections of typical views of objects lying in three-dimensional space", Gregory notes that "the parts of the figure corresponding to distant objects are expanded and the parts corresponding to nearer objects reduced". He states the same principle more simply when he writes: "Those parts of the figures which would normally be further away in 3-D space appear too large in the illusion figures"[3]. These principles are applied to a series of illusions, including those of Müller-Lyer, Ponzo and Hering. Gregory therefore postulates a common process modifying retinal images in constancy scaling and in the perception of illusory figures.

If this general principle operates, it is difficult to understand why the distorting process does not occur under all the conditions in which distance is perceived in two-dimensional figures. In Ponzo's figure the same one of the two central lines appears longer, no matter whether it is seen as nearer or farther after rotating the figure through 180°. Similarly when only the top or bottom half of either forms of Hering's illusion is inspected, the parallel lines appear to be distorted, no matter which way the perceived depth or distance appears to be in the background field. Further, Gregory's contention that "the scaling can be set directly by depth features of flat figures"[4] does not seem to be supported experimentally in all illusions. Green and Hoyle[5], for example, found that the Poggendorff illusion did not give rise to 3-D perception under reduced cue conditions. Their finding also is substantiated by Gibson[6], who reports that when the texture of a pattern becomes indeterminate the observer no longer sees the dimensions of a surface but a depthless shape perceived in the frontal plane.

Gregory's predictions, when applied to different orientations of visual illusions, are therefore not supported. In fact the illusions are more stable than Gregory's predictions would suggest, since changing the constancy relationships does not necessarily change the illusory effects. However, if the constancy interpretation of illusions is to be accepted it must be applicable to all conditions of inspection, and not only to a single orientation of the figure.

Although we do not have an alternative general explanation of the cause of visual illusions, we would offer some suggestions concerning specific factors operating in the illusory patterns being discussed. First, the relative position of the two horizontal lines in Ponzo's figure seems more important than the distance at which they appear to be located. Then, the distortion in Hering's illusion, or in Gibson's texture gradient, occurs as a function of the density of background lines: that is, the closer together these lines are, the more distorted the illusory lines appear, irrespective of which part of the pattern looks nearer or farther away. Further, predictions can only be made about which sections of the illusory lines will be more distorted, and not about the direction of distortion, that is whether the illusory lines will appear closer together or farther apart, as Gregory's account would require. Finally, some of the illusions considered by Gregory (that is, Hering's, Gibson's texture gradient, Orbison's field of concentric circles and the Necker cube) disappear entirely when the viewing slant is altered or when they are viewed from a distance, although the cues for depth, which set the constancy scaling, still operate[7]. We conclude, therefore, that constancy scaling operates only under a set of very limited conditions of inspection of illusory figures.

There are several hints in the literature of perception of a possible tie-up between constancy and the illusions, but Tausch[1] seems to have produced the first reasonably solid treatment, described clearly by Teuber[2], though he has not developed a fully consistent theory. Brown and Houssiadas's reference to J. J. Gibson's *The Perception of the Visual World*[3] in this connexion is surprising, for Gibson holds a view of constancy which precludes this kind of theory. Gibson starts off (p. 163) somewhat disconcertingly: "The aim of this chapter is ultimately to show that the question of why things retain their sizes and shapes under different circumstances is a false question". (The rest of the chapter is, however, devoted to this question.) He develops a theory of depth perception which he attributes to Koffka[4]—the size-at-a-distance theory—which is that all three spatial dimensions are equally available to the perceptual system. But in denying that depth has to be specially computed, Gibson rejects the notion of constancy scaling essential to this theory of the illusions. When Gibson uses the word 'scale' he is evidently not referring to a process of size adjustment normally giving constancy, for several times he explicitly denies such processes in depth perception.

Gibson says of an illusion figure (p. 181): "All three cylinders are the same size on the page; it is not an illusion at all but a demonstration that apparent size depends on apparent distance". But the fact is that illusion figures are not seen as lying in depth when presented on normal textured paper: hence the problem. It was for this reason I removed background texture by using luminous illusion figures for experimental purposes.

I think Brown and Houssiadas are incorrect in attributing this kind of theory to Gibson, while his account of the illusions seems the least satisfactory part of his treatment of perception.

The main question raised by Brown and Houssiadas is whether the distortions occur under all conditions in which distance is perceived in a two-dimensional figure.

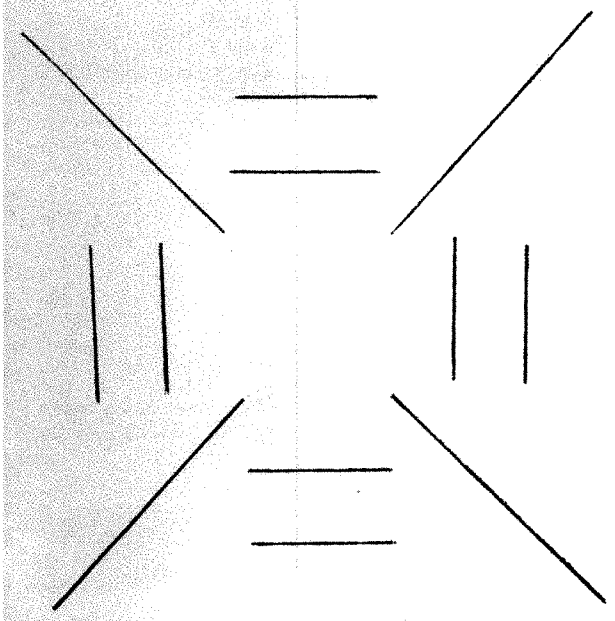

Fig. 1. This shows four differently orientated Ponzo figures. Brown and Houssiadas argue that the illusion should change with the orientation: but the perspective is unchanged, and so this is incorrect

(Actually, as I point out[5], it need not be perceived; for we must suppose that constancy scaling can be set directly by perspective and other depth cues, even when these are countermanded by other features such as the texture of the background. Perspective depth is 'paradoxical'—suggested but not seen as in the real world of objects lying in space.) Now, they are mistaken in regarding their test cases as exceptions; for when a perspective figure is rotated, the perspective does not change. What changes is the effective viewing position, and this is a very different matter. This should be clear from the example given of four differently orientated Ponzo figures—their perspective is the same and so is the illusion. They lie respectively on the 'ground', to the sides and in the 'sky'. The same consideration holds for the case of the partly obscured Hering figure, and the rest.

Brown and Houssiadas give insufficient data on their final point for a useful comment, but it should be pointed out that there is only one distance from which a given perspective is strictly correct. Their findings might be very important in this connexion.

So far no valid objections seem to have been raised to my form of the theory[5]; but the evidence for it is rather indirect. I have, therefore, devised a technique for obtaining objective measures of apparent depth. This makes it possible to relate directly apparent depth with illusory distortions. An established relation between apparent depth in the luminous illusion figures, where depth is not countermanded by texture, and the extent of the illusion in the same figures but viewed on a normal texture background, would be very strong evidence for the theory. Working with Miss Linda Townes at the Massachusetts Institute of Technology, and in a preliminary experiment with Mr. I. Morrell at Cambridge, England, I have found just such a relation.

How to measure apparent depth. The basic scheme is to use binocular depth vision (either the range-finder effect of convergence, or disparity between the retinal images) as a standard against which to measure depth given by perspective. This is done, using convergence, by keeping both eyes open but allowing only one to see the (generally luminous) display figure, by cross-polarizing the light from the display to one eye. A small dim reference light is introduced into the display by means of a half-silvered mirror, this light being seen by both eyes. Its distance is adjusted until it appears the same distance as any selected part of the display figure, viewed with a single eye. Since the reference light is seen by binocular vision, we thus obtain a measure of depth as determined by perspective features of the figure. The positions of the reference light are automatically recorded on graph paper, and so we obtain a complete plot of visual space.

So far I have used this technique on the Müller-Lyer illusion, and on ambiguous figures such as the Necker cube. I am now working on the Poggendorff illusion, and find fluctuating depth with related changes in the illusion. The results on the Müller-Lyer are remarkable: there is a correlation of about 0·9 between the extent of the illusion (as determined by the fin angle; measuring the illusion by setting an adjustable comparison line to equality) with the same figures but luminous, their depth being measured with this technique.

My suggestion[5] that figural after-effects are due to constancy scaling being upset by lengthy fixation of depth clues can now be tested.

A further fact, which seems to hold for all the illusions where background produces a distortion, is that the illusion evidently disappears when the affected lines are displaced in depth from the disturbing background, by introducing disparity with a stereoscope.

This work was supported by the National Aeronautics and Space Administration. I thank Prof. H-L. Teuber for his advice.

Alpha-frequency of Electroencephalogram and a Stabilized Retinal Image

IT is known that the alpha rhythm is suppressed in most subjects when patterned targets are viewed in normal vision[1]. It is now also well known[2–4] that when a pattern is viewed as a stabilized retinal image, perception of it in whole or in part may be lost intermittently. It is evidently of interest to discover what modification, if any, of the alpha component of the human electroencephalogram occurs when a stabilized pattern has actually disappeared.

Until quite recently, methods of achieving a stabilized image have involved the wearing of contact lenses. Despite the fact that compensation for eye movements by this particular method is sufficiently good to promote fragmentation and occasional total disappearance of the image, some mechanical destabilization due to minute translations of the lens relative to the scleral surface must occur[5]. Though this cannot account for all reappearance of the image[6], it undoubtedly induces periodic regenerations of the order of three or four seconds, and since alpha develops relatively slowly in normal situations[7], a clear-cut correlation with such brief events might be hard to achieve. (Since this communication was written, we have heard that comprehensive investigations of the relationship of alpha to image disappearance using the contact lens method of stabilization have been performed by Fender *et al.* at the California Institute of Technology, with results in general agreement with those reported here.)

The after-image method of investigating stabilized patterns[8] removes destabilization as an interfering variable, and, since in any sequence of viewing a prolonged after-image, total disappearances of the pattern tend to become increasingly more common with the passage of

time, any correlation that exists between disappearance phenomena and the electroencephalogram should manifest itself more clearly. In fact, if suppression of alpha is, as has been proposed, associated with the perception of patterns, then one would expect more frequent occurrence of alpha towards the end of experimental sessions.

In this experiment the electroencephalogram was recorded from a single pair of chlorided silver scalp leads placed over the occipital and parietal areas about 2 in. from the midline. The amplifier sensitivity was 50 μV/cm over the 5–20 c/s band and the recording paper moved at a speed of 1 cm/sec.

Each trial was of 4-min duration from the time of the initial flash. The subject lay relaxed on a couch in a dimly lit room and was instructed to close his eyes directly the flash had been given, and report, by pressing a key, the occasions on which the target had totally disappeared. The image was a simple patterned target, consisting of a square with an inscribed cross. The figure in outline was cut from thick black paper and illuminated from behind by a 1,000-joule flash of 25 msec maximum duration. The flash was at a distance of 6 ft. from the subject's head, the image subtending at this distance a retinal angle of 5°. The target was dimly illuminated from behind by a low-power bulb for a few seconds before the flash to afford the subject a proper fixation point.

After the experiment, records were divided into 1-min sections and periods of clear alpha activity were marked off visually. Both frequency and amplitude were used as criteria and measurements were made independently by two observers. Disagreement between the observers was found to be small.

The subject's record indicated that total disappearance rarely, if ever, occurred in the first quarter (1 min) of the run, and began to occur towards the end of the second quarter. The pattern had apparently totally disappeared for the final 1·5 min of the trial. Fig. 1*a* plots the total time for which alpha was present in each minute following the flash. The bars are means for four trials on one subject, the standard error of the means being indicated by the vertical lines. Note that alpha was almost entirely absent in the first 2 min, and increased rapidly during the final two, reflecting the incidence of recorded disappearances.

Two independent sets of control observations were considered to be desirable. In the first set, the subject's 'resting' alpha was recorded. The subject relaxed with open eyes in the dimly lit room for 30 sec, this being followed by a 4-min period with eyes closed when the electroencephalogram record was taken. Distribution of alpha for the 4-min sessions is plotted in Fig. 1*b*. It will be noted that alpha began to occur about 15 sec after the eyes had been closed, and in the second quarter had reached a level only achieved in the fourth quarter after the patterned flash.

It was recognized that the observed alpha suppression might be due to the after-effects of the bright flash used to plant the after-image on the retina, and not necessarily to the perception of a patterned target. To take account of this possibility, a complete series of measurements was made following a flash in which no pattern or contours were present. For this series of trials the black paper mask and pattern 'cut-out' were moved from the front of the flash apparatus, and the whole device was covered with diffused tracing paper and fired within 12 in. of the subject's eye. This produced a brilliant explosion of light which completely filled the subject's monocular field. With the flash intensity remaining at 1,000 joules, in this control the actual intensity expressed in terms of input or excitation of the retina must have been many times greater than when the pattern 'mask' was used. The flash was described by subjects as a startling and 'somewhat painful' experience. Fig. 1*c* indicates that while alpha was certainly suppressed for a period, as might be expected owing to the strength of the flash in such proximity to the eye, it began to return in the first minute,

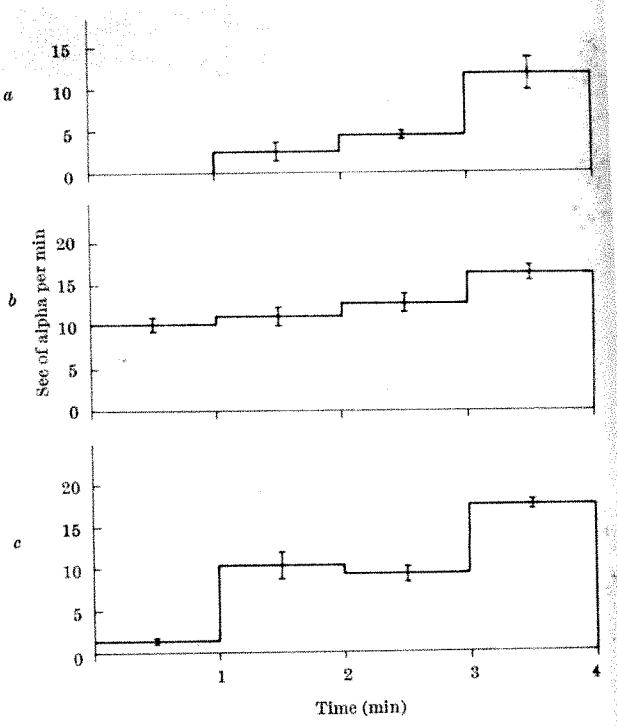

Fig. 1

and by the end of the second minute had risen to the 'resting' level. It is clear that the general suppression of alpha noted in Fig. 1*a* is not simply a function of visual shock or general disturbance of the subject. The complete experiment was repeated on a second subject with almost identical findings.

It therefore seems evident that the suppression of alpha is related to the presence of a pattern in the visual field. How closely this is linked to 'attentional' phenomena is not clear, though it should be mentioned that the key-pressing task, which might conceivably be expected to inhibit alpha somewhat was deliberately confined to the basic experimental condition (that is, the subject pressed the key when the target was absent). (In fact, pilot investigations had indicated that the muscular act of random key-pressing did not seem to affect alpha in any obvious way. Typically in the experimental sessions, the key was depressed only four or five times in a 4-min run. The role of 'attention' in relation to pattern perception cannot, of course, be established from a preliminary investigation of this kind. Nevertheless, since the subjects eyes remained closed in all three conditions of the experiment, and since in all conditions the visual input did not change after the single initial flash, it now seems to be certainly established, perhaps for the first time, that neither of these two variables plays a vital part in the promotion or suppression of alpha. Rather, the independent importance of signals that define contours, boundaries and possibly 'shape' seems to be demonstrated.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 19

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. L. Garraway: "Studies on certain Organo-Sulphur Compounds as Fungicides".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. Klein (Stockholm): "The Immunology of Experimental Tumours".*

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Enfield Technical College, Queensway, Ponders End, Enfield, Middlesex), at 7 p.m.—Dr. T. R. E. Kressman: "Ion Exchange".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Eric E. Shipton, C.B.E.: "Over the North Patagonian Icecap".

Tuesday, October 20

SOCIETY OF CHEMICAL INDUSTRY, Agriculture Group (at 14 Belgrave Square, London, S.W.1), at 2 p.m.—Short Paper Meeting on "Microanalysis in Agriculture".

PHOTOBIOLOGY GROUP (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Scientific Meeting and Annual General Meeting.

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. O. A. Kerensky and Mr. Gordon Little: "Medway Bridge—Design"; Mr. M. Kier, Mr. Frode Hansen and Mr. J. A. Dunster: "Medway Bridge—Construction".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. F. Brailsford and Mr. R. Fogg: "Anomalous Iron Losses in Cold-Reduced Grain-Orientated Transformer Steel".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. F. K. Hare: "New Wings for Climatology—a Science Reborn" (Inaugural Lecture).*

UNIVERSITY OF LONDON (in conjunction with the Society for the Study of Addiction, at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. Leonard Goldberg: "Dependence on Alcohol" (J. Y. Dent Memorial Lecture in Pharmacology).*

UNIVERSITY OF LONDON (in the Beveridge Hall, Senate House, London, W.C.1), at 5.30 p.m.—Prof. Sir Robert Platt: "The Ethical Basis of Medical Science". (First of fourteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

INSTITUTION OF MECHANICAL ENGINEERS, RAILWAY ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Traction-Motor Problems".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Brighton College of Technology Chemical Society, at the Brighton College of Technology, Lewes Road, Brighton, Sussex), at 7 p.m.—Prof. Keith Simpson: "Some Applications of Science to Crime Investigation".

Wednesday, October 21

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. P. M. Saunders: "Sea Smoke and Steam Fog"; Mr. A. A. Townsend: "Natural Convection in Water Over an Ice Surface".

BRITISH COAL UTILISATION RESEARCH ASSOCIATION (at the Federation of British Industries, 21 Tothill Street, London, S.W.1), at 5.30 p.m.—Prof. A. R. J. P. Ubbelohde, C.B.E., F.R.S.: "The Chemistry of Carbon and Graphite" (Thirteenth Coal Science Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. G. G. Gouriet: "Through Communications to Electronics" (Chairman's Address).

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. J. L. Synge, F.R.S.: "Hamiltonian Theory of Rays and Waves". (Further lectures on October 22 and 23.)*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, RADAR GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. M. G. Henley: "The Effect of Tolerances on Automatic Landing".

INSTITUTION OF MECHANICAL ENGINEERS, HYDRAULIC PLANT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "What Don't We Know About Non-Return Valves?"

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "The Determination of Phosphorus Applied to Organic, Inorganic and Biological Materials", introduced by Mr. E. Q. Laws.

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, W.C.1), at 7 p.m.—Prof. J. Z. Young, F.R.S.: "An Experimental Approach to Neurology".*

INSTITUTION OF ENGINEERING INSPECTION (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.15 p.m.—Mr. R. S. Sharpe: "The Detection and Assessment of Defects".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION, LEA VALLEY SUB-SECTION (at the College of Further Education, Hagsdell Road, Hertford), at 7.30 p.m.—Dr. R. S. Cahn: "The Future of Chemical Publications".

Wednesday, October 21—Thursday, October 22

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINES GROUP (at the College of Advanced Technology, Gosta Green, Birmingham, 4)—Symposium on "Thermal Loading of Diesel Engines".

Thursday, October 22

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Colin Smith: "Words, Words, Words—Satire, Thinker or Humbug?"*

UNIVERSITY OF LONDON (in the Recital Room, Goldsmiths' College, New Cross, London, S.E.14), at 4.45 p.m.—Dr. Michael Kaye: "Philosophy Today".*

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. D. G. Armstrong: "Variations in Stroke Waveform in a Laboratory Jig"; Mr. A. G. Moncrieff: "Theory of Thickener Design Based on Batch Sedimentation Tests".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. K. A. Kermack: "*Aegialodon dawsoni*, the Earliest Known Trituberculosectorial Tooth"; Dr. J. R. E. Mills: "Form and Function in the Teeth of Tenrecoidea".

INSTITUTION OF CIVIL ENGINEERS, ENGINEERING MANAGEMENT GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Selection for Management in the Army", introduced by Col. R. L. Clutterbuck.

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Colonel H. Randal Steward: "Twenty-five Years of Make and Mend" (Presidential Address).

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—Mr. J. Zbrozek: "Atmospheric Gusts".

OIL AND COLOUR CHEMISTS' ASSOCIATION (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. H. Oosterhof: "Inherent Properties of Paint Latex Films in Relation to Their Performance".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex), at 7 p.m.—Mr. R. A. Saunders: "The Uses of Mass Spectrometry in Organic Chemistry".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION, KENT SUB-SECTION (at the Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent), at 7 p.m.—Prof. C. C. Addison: "Liquid Sodium".

Thursday October 22—Friday, October 23

POWDER METALLURGY JOINT GROUP OF THE IRON AND STEEL INSTITUTE AND THE INSTITUTE OF METALS (in the Hoare Memorial Hall, Church House, Great Smith Street, London, S.W.1), at 10 a.m. daily—Annual Meeting.

Friday, October 23

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Mechanics of Sugar-Cane Crushing".

ROYAL AERONAUTICAL SOCIETY, ROTOCRAFT SECTION (at 4 Hamilton Place, London, W.1), at 6 p.m.—Prof. H. Focke: "German Thinking on Rotary Wing Development" (Fifth Cierva Memorial Lecture).

OCCAM SOCIETY (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. A. Healey: "The Philosophy of Finance".

Saturday, October 24

JOINT BIOLOGY COMMITTEE (in the William Beveridge Hall, University of London, Senate House, Malet Street, London, W.C.1), at 10 a.m.—One-Day Course on "The Educational Value of Biology".

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss Mildred Archer: "Birds and Flowers in Indian Painting".*

Monday, October 26

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. B. Ackner: "Stress and Psychosomatic Disorders".*

MEDICAL RESEARCH COUNCIL (at the National Institute for Medical Research, Mill Hill, London, N.W.7), at 4.30 p.m.—Prof. Sven Gard (Karolinska Institutet, Stockholm): "An Approach to the Study of Virus Synthesis".

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. C. Koeman: "The Life and Work of Lucas Janszoon Waghenaer" (The Eva G. R. Taylor Lecture).

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. K. L. Manchester: "Some Aspects of the Action of Insulin" (Further lecture on November 2).*

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Prof. A. Rupert Hall: "Galileo and the Science of Motion".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. A. L. Cullen: "Millimetre Wave Examination of Gas Discharges".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.R.E.–I.E.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Colloquium on "Design Automation".

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. Julian Royle: "A Modern Approach to Colour Printing".

ROYAL AERONAUTICAL SOCIETY, HISTORICAL GROUP (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. S. B. Jackson: "The Parachute—an Historical Review".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER or ASSISTANT LECTURER (with a good honours degree and preferably some teaching, research or industrial experience) IN PHYSIOLOGY IN THE DEPARTMENT OF BIOLOGY—The Academic Registrar, Brunel College, Woodlands Avenue, Acton, London, W.3 (October 23).

READER IN MECHANICAL ENGINEERING; and a LECTURER or ASSISTANT LECTURER IN MECHANICAL ENGINEERING—The Academic Registrar, Brunel College, Woodlands Avenue, Acton, London, W.3 (October 23).

CHAIR OF NUMERICAL ANALYSIS WITHIN THE DEPARTMENT OF APPLIED MATHEMATICS—The Registrar, The University, Liverpool (October 30).

POST-DOCTORAL FELLOW IN THE DEPARTMENT OF CHEMISTRY, for research on the structure and adsorptive properties of active charcoals—The Professor of Chemistry, The University, Hull (October 31).

RESEARCH ASSISTANT or SENIOR RESEARCH ASSISTANT (with a qualification in electrical engineering or physics and industrial or research laboratory experience) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, to assist in an experimental investigation, supported by D.S.I.R., into the high voltage breakdown of gases—The Secretary, Welsh College of Advanced Technology, Cathays Park, Cardiff (October 31).

TUTORIAL STUDENT (with a good honours degree or an equivalent qualification) IN THE DEPARTMENT OF CHEMISTRY, to carry out research on polyelectrolytes—Prof. G. M. Burnett, Department of Chemistry, University of Aberdeen, Aberdeen (October 31).

X-RAY CRYSTALLOGRAPHER (with previous research experience in X-ray crystallography) IN THE PHYSICS DEPARTMENT, for crystallographic studies of materials (including single crystals) at high pressures—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (October 31).

DEMONSTRATOR IN PATHOLOGY—The Registrar and Secretary, The University, Bristol (November 2).

SECOND CHAIR OF PHYSICS—The Secretary and Registrar, The University College of North Wales, Bangor, North Wales (November 2).

LECTURER (with at least an honours degree of high standing in mathematics or equivalent qualifications, and able to produce evidence of strong research interests and experience) IN THE SCHOOL OF MATHEMATICS, The University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (November 6).

RESEARCH ASSISTANT (with an honours degree in botany or agricultural botany) to investigate the effects of storage conditions on the life span of crop seeds—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge (November 6).

SENIOR LECTURERS, LECTURERS or ASSISTANT LECTURERS IN PHILOSOPHY—The Secretary, University of Lancaster, Bailrigg House, Lancaster (November 7).

CHAIR OF PHYSIOLOGY at Makerere University College, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 8).

CHAIR OF STATISTICS at Queen Mary College in association with the Institute of Computer Science—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 9).

LECTURER (with special qualifications and interests in economic geography) IN GEOGRAPHY—The Secretary, The Queen's University of Belfast, Belfast, Northern Ireland (November 10).

LECTURER IN PURE MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (November 13).

LECTURER/SENIOR LECTURER IN PHILOSOPHY at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 13).

LECTURER (with a good honours or postgraduate degree in philosophy) IN PHILOSOPHY at the University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (November 14).

LECTURER IN GEOGRAPHY at the University of Otago, Dunedin, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 15).

LECTURER (suitably qualified graduate with specialism in educational sociology) IN EDUCATION at the University of Otago, Dunedin, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 15).

READERS, SENIOR LECTURERS and LECTURERS IN PHYSICS—The Registrar, University of Warwick, Coventry (November 16).

SENIOR LECTURER or LECTURER (with a special interest in vertebrate zoology) IN ZOOLOGY at the University of Khartoum—The Registrar, University of Khartoum, c/o The Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 30).

MYCOLOGIST (with a good honours degree) to work on soil-borne diseases of cereals—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (December 31).

AGRICULTURAL OFFICERS (with a degree in agriculture and, preferably, with several years experience of agriculture in the tropics) in Fiji, for extension work, mainly with peasant farmers (crops include cocoa, coconuts, groundnuts, pulses, rice and livestock)—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/62/01.

CHIEF PHARMACIST, Category V (male or female) at the Central Middlesex Hospital, Park Royal, London, N.W.10—The Group Secretary, Central Middlesex Group H.M.C., Acton Lane, London, N.W.10.

JUNIOR RESEARCH ASSISTANT for fundamental research on the chemistry and physical chemistry of soil minerals—Prof. R. M. Barrer, F.R.S., Chemistry Department, Imperial College, London, S.W.7.

RESEARCH ASSISTANT (with qualifications in chemical engineering, chemistry or physics or another relevant discipline) IN THE DEPARTMENT OF CHEMICAL ENGINEERING, to work on a new project in the field of liquid–liquid extraction of metal ions, supported by a D.S.I.R. research grant—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 23/G.

RESEARCH FELLOWS (with a good honours degree in engineering, physics, or mathematics or their equivalent, interested in acoustics and vibrations, and preferably experience in research or in industry) at the Institute of Sound and Vibration Research—The Secretary and Registrar (Room 9), The University, Southampton.

REPORTS and other PUBLICATION

(not included in the monthly Books Supplement)

Great Britain and Ireland

Catalogue of Publications of the Cement and Concrete Association cu available for distribution in the United Kingdom. Pp. 40. (Londo Cement and Concrete Association, 1964.)

Bulletin of the British Museum (Natural History). Entomology. V No. 6: Diptera from Nepal. The Fruit Flies (Diptera: Tephritidæ). Elmo Hardy. The Blow Flies (Diptera: Calliphoridæ). By Maurice T. Pp. 145–179. (London: British Museum (Natural History), 1964.) 14

The Institution of Electrical Engineers. *Current Papers*, No. 1 (. 1964). Pp. 4. Published monthly. Annual subscription 20*s*. (L The Institution of Electrical Engineers, 1964.)

Transactions of the Royal Society of Edinburgh. Vol. 66, No. 1: Structure of Some Petioles Associated with *Rhetinangium* Gordon. By G. Long. Pp. 1–8 + 2 plates. 6*s*. Vol. 66, No. 2: Observations on gotid Eurypterids. By Charles D. Waterston. Pp. 9–34 + 4 plates. 1 Vol. 66, No. 3: A Petrified Lower Carboniferous Lepidodendron Sl Rooting Organs Identified with *Calamopsis* Solms-Laubach. By Alt Long. Pp. 35–48 + 4 plates. 10*s*. 6*d*. (Edinburgh: Royal Soci Edinburgh, 1964.)

Department of Scientific and Industrial Research. Summary of P of the Geological Survey of Great Britain and the Museum of Pr Geology for the year 1963. Pp. iii + 99. (London: H.M. Stationery 1964.) 6*s*. 6*d*. net.

PRECISE MEASUREMENTS WITH THE NEW CAMBRIDGE AC/DC COMPARATOR

Precise a.c. measurements for calibration and testing can be made quickly and simply with the NEW Cambridge Comparator.

Voltage: Ranges from 0.5 to 300 volts
Current: Ranges from 5 mA to 3 amps
Frequency: From 25 to 20 000 c/s
Accuracy: ±0.05% (up to 1.5 amps and 150 volts)
Resistance: 100 ohms per volt
Transfer element: Vacuo-junction
AC/DC transfer error: 0.002%
Discrimination: 0.01%

Fitted with a mains supply unit to provide a high stability d.c. reference current, the comparator incorporates a standardising potentiometer—the only external accessories required being a standard cell and a galvanometer. A built-in meter indicates approximate a.c. values and the controls can be set to avoid overloading the vacuo-junction. In the event of accidental damage however, the vacuo-junction can be replaced easily without upsetting the calibration.

Send for list 353N. For future publications, write for mailing form N/ 10/64

Cambridge **AC/DC COMPARATOR**

Cambridge Instrument Company Limited, 13 Grosvenor Place, London, S.W.1

CLASSIFIED ADVERTISEMENTS

are charged at 12s. for the first line and 6s. per line thereafter. Lines in capitals or containing words in capitals 12s. per line. Semi-displayed £4 16s. per single column inch. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, Estrand, London.

APPOINTMENTS VACANT

UNIVERSITY COLLEGE OF NORTH WALES
BANGOR

Applications are invited for the Chair of Materials Science within the School of Engineering Science. The salary will be not less than £3,400 per annum, together with F.S.S.U. benefits, and the appointment will be from a date to be arranged with the successful applicant.

Twelve copies of the application should be sent by November 2, 1964, to the Secretary and Registrar, The University College of North Wales, Bangor, from whom further particulars may be obtained.

PILKINGTON BROTHERS LIMITED

require a

LIGHTING ENGINEER

to work in a new and expanding Illuminating Laboratory helping to provide an independent Daylight Consultancy Service for architects. There will be opportunities for developing original experimental methods and new prediction techniques.

It is not essential to have studied daylight before, but a thorough knowledge of lighting, an interest in research and preferably an I.E.S. Diploma are desirable.

Please quote HO/TS8 in applying to
Mr. J. C. Pritchard,
Group Staff Department,
Pilkington Brothers Limited,
Prescot Road, St. Helens.

MACAULAY INSTITUTE FOR SOIL RESEARCH

Applications are invited from graduates with first- or good second-class honours in Mathematics with Statistics, or with a Diploma in Statistics, for a vacancy in the Statistics Section. The duties are mainly concerned with the design and analysis of field and laboratory experiments. The appointment will be made in the Scientific Officer grade, starting salary within the range £815 to £1,348 per annum, according to age, qualifications and experience. Superannuation under F.S.S.U.

Forms of application may be obtained from the Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, to whom they should be returned before October 31, 1964.

REGIUS CHAIR OF ZOOLOGY
UNIVERSITY OF GLASGOW

The Secretary of State for Scotland invites application for the

REGIUS CHAIR OF ZOOLOGY

in the University of Glasgow, which will fall vacant on January 1, 1965. A note of the conditions of appointment may be obtained on request from the Secretary, Scottish Education Department, Room 206, St. Andrew's House, Edinburgh, 1. Three copies of applications, accompanied by the names of three referees, should be sent not later than October 31, 1964, to the Private Secretary, Room 505, St. Andrew's House, Edinburgh, 1.

MSL

A candidate's identity will not be disclosed unless he gives permission after a confidential discussion.

Research and Development Scientist

for a company making and selling trawler equipment for trawlers of all sizes, through branches in the U.K. and subsidiaries and agents in the world's trawling bases.

The Board supports the view of the White Fish Authority—"that progress in the industry has been hampered in the past by a shortage of highly qualified technologists" (W.F.A. Annual Report 1964). Therefore they intend to appoint a 30–35-year-old graduate scientist to initiate and develop an R. and D. programme for the whole company. While the immediate task is trawl design, the actual field for investigation is wide and may range from hydrodynamics to fish reaction. Thus relevant experience will be in underwater research, hydrodynamics, possibly aerodynamics. The ideal combination would be experience of both technical development of plaited and twisted synthetic twines and marine research work.

Foreign travel in pursuit of new ideas and techniques will be encouraged. Starting salary £2,500. Pension, car provided. Success will bring an early appointment to the Board. Please write to C. L. F. McMillan quoting U.6816, and stating how each requirement is met.

MANAGEMENT SELECTION LIMITED
17 STRATTON STREET, LONDON, W.1.

PARKE-DAVIS

have a vacancy for a

CHIEF TECHNICIAN

in the Department of Pharmacological Research.

The work involves administration of laboratory and animal units, including supervision of technical staff.

Applications, giving qualifications and experience, should be addressed to:

The Personnel Manager,
PARKE, DAVIS & COMPANY,
Staines Road, Hounslow, Middlesex

UNIVERSITY OF BRISTOL

Applications are invited for the post of Lecturer (Grade II) in Pure Mathematics within the Department of Mathematics tenable from January 1, 1965, or as soon as possible thereafter. Salary range £1,400 by £85 to £2,505 per annum with F.S.S.U. superannuation.

Further particulars can be obtained from the Registrar, Senate House, Bristol, 2, to whom applications should be sent by October 30.

TECHNICIAN TO ASSIST WITH RESEARCH on the metabolism of water and electrolytes. Good histological experience is essential. Other techniques involved will include photomicrography and tissue culture. Commencing salary up to approximately £750 per annum according to age, qualifications and experience.—Applications, in writing, to Dr. J. M. N. Boss, Department of Physiology, Medical School, University Walk, Bristol, 8.

PROMOTING INDUSTRIAL RESEARCH IN BRITAIN

*RESEARCH FOR INDUSTRY, 1963** follows the usual pattern of recent years, comprising the report of the Industrial Grants Committee and the directory of the research associations, together with brief progress reports on the work of ten associations, the grants of which came up for renewal during the year. There is also a short article by Sir Charles Goodeve on the research associations as a collaborative network. After noting the establishment of the Standing Consultative Conference on Textile Research and the Consultative Committee of Directors of Food Research Organizations (which has been meeting for some 10 years), Sir Charles directs attention to the technical role of the Committee of Directors of Research Associations, formed in 1945, and to the objectives of the Industrial Automation Group set up by that Committee in 1963. The contracting process which marked the 1962 report continues, and the report is now no more than 54 pages (15 of which are occupied by the directory) compared with 75 in 1962, 140 in 1961, and 148 in 1960.

In the aggregate, therefore, *Research for Industry* now supplies no more information than was supplied about the research associations before the Department of Scientific and Industrial Research began to report on them separately from its annual report—in fact the 1963 report supplies less. The annual reports of the individual research associations increasingly provide the principal sources of information, and, although the report of the Industrial Grants Committee deals with some major questions of policy, it scarcely provides the wide conspectus that is desirable. Certainly it does not meet many of the major points of criticism which have been put forward in many recent discussions on the general functions of the research associations. There is, in fact, nothing in this report to dispose of the criticism of triviality in the amounts of grants to some associations, which has been made in influential quarters, or to indicate that the Council itself or its Industrial Grants Committee is aware that even the most carefully devised scheme of grants can be ineffective if the income of a research association or laboratory does not reach at least a certain minimum level. The decision of the British Internal Combustion Engine Research Association to transform itself, for lack of industrial support, into a sponsored research institute is a quiet reminder.

The total income of the grant-aided research organizations rose from £8·8 million in 1962 to £9·5 million in 1963: the grant from the Department of Scientific and Industrial Research increased from £1·96 million to £2·1 million. During the past two years the grant policy has radically changed; a flat rate is now being offered in order to stimulate growth or attract support from new sources—except when incentives are necessary. In 1963, 14 out of 16 associations were given a flat rate over a range of industrial income, and the grants represented 30–100 per cent of the industrial income. There is also a new approach to minimum and maximum limits for grants: the minimum income is no longer set so high as to imply a sudden fall in income if the association fails to raise additional industrial income in the first year of a new quinquennium, while the maximum grant represents a reasonable target for growth if the industry is disposed to achieve it, and if this target is exceeded the maximum grant may be extended.

The Industrial Grants Committee notes two further important points. The new policy is designed to avoid directors of research becoming too preoccupied with securing additional industrial support in order to qualify for a grant, and it is also intended to enable research associations to plan their future programmes without fear of discontinuities in income. Both these tendencies could help to eliminate some of the trivialities or waste which have been the subject of criticism, and the scheme of 'ear-marked' grants in support of selected research and development projects, which came into operation in 1963, could also help. Although the Industrial Grants Committee supported in principle 9 out of 13 applications for such grants, only one such grant was offered and accepted during the year—that to the British Welding Research Association for work on metal fatigue—though five more have been offered since the end of the year.

Two of these are also to the British Welding Research Association. One, of up to £84,000 over five years, is in support of research in serious welding problems, while the other, of up to £15,300 over five years, is for research into the brittle fracture of metals, and is part of a broad programme involving university departments as well as the Research Association. The other three ear-marked grants are: half the cost, estimated at £114,700 over three years, of an investigation by the Cotton Silk and Man-made Fibres Research Association of new methods of spinning; up to half the cost of a project (£14,000 over two and a half years) of the British Launderers' Research Association to speed the introduction of automation in its industry, and one of up to £39,400 over four years to the eight textile research associations to support research on water conservation and treatment of effluents throughout the textile industry.

The Industrial Grants Committee recognizes that the introduction of the new ear-marked grants raises issues of policy, including the broad question of how Government grants should eventually be related to the support secured by research associations from their industries. Clearly, the new policy could involve to some extent the Council of Scientific and Industrial Research determining the direction which the research pursued by particular associations or groups of associations should follow, and this has far-reaching implications which call for careful consideration. The Industrial Grants Committee itself suggests that the new terms awarded in 1963 to the Association of Special Libraries and Information Bureaux (Aslib) may provide a pointer to future developments, although Aslib is not typical of research associations. According to the new terms, separate grants were negotiated for research and for other activities; under the research part of the grant, virtually the full cost, up to an annual limit of £20,000, comes from the Government,

* Department of Scientific and Industrial Research. *Research for Industry, 1963*: a Report on Work done by Industrial Research Associations in the Government Scheme. Pp. v+54+19 plates. (London: H.M. Stationery Office, 1964.) 5*s*. 6*d*. net. See also p. 334 of this issue of *Nature*.

while for the general activities the grant is on the usual 50 per cent basis of grant-earning income up to a maximum of £17,500.

Some such arrangements might perhaps permit the ear-marked grant system to work smoothly, though where the amount of such grants is high or of the other activities and research carried out by the research association is relatively small, it would be worth while considering whether the research association model is appropriate or should, in these cases, be replaced by a structure of the research station type. Obviously there are other considerations, but the question of support from a reluctant or backward industry is far from being solved, in Britain or elsewhere, and deserves more penetrating and constructive thought than it has yet received. In this connexion it is to be noted that the Industrial Grants Committee has itself called for a thorough review of the research role, control and sources of support of the British Coal Utilization Research Association, but on different grounds—that of probable dominance by one or two large member organizations. Meanwhile, renewal of grant has been recommended for a further five years ending December 31, 1968, and it is hoped that the enquiry in progress will result in a formula which will either strengthen the laboratory in its work for the coal industry or define its functions more widely in relation to fuels in general.

Two other matters noted in the Industrial Grants Committee's report deserve comment. The most satisfactory feature of the scheme for special assistance to industry has been the variety of projects undertaken. This scheme, started in 1959, was planned to run for five years to help research associations in setting up or in improving liaison and information services, and generally in aiding the application of research results in industry. Almost half the research associations have participated. The Production Engineering Research Association, for example, employed a specially equipped mobile laboratory to give direct assistance to member firms in adopting new techniques to production operations. The British Non-Ferrous Metals Research Association demonstrated and developed prototype instruments for control of production processes and inspection of production. The British Welding Research Association runs special advisory services on the design of welded structures, the British Iron and Steel Research Association organizes similar services on ergonomics and safety, while the British Leather Research Association runs a special liaison service on effluents.

While the results of these projects are not easily assessed in economic terms, there have been some important results, notably in the baking industry through the introduction of the Chorleywood Bread Process, in the wool industry through the wider use of the Wool Industries Research Association 'Cop-Grader' and in production engineering through the introduction of improved metal-cutting and metal-forming techniques. Apart from this, the schemes have substantially influenced the industries served and they may well have encouraged research-mindedness generally. Most associations are continuing their projects as part of their normal programme of work.

The other matter is the extension to England and Wales of the scheme for the appointment of industrial liaison officers in technical colleges pioneered in Scotland by the Department in association with the Scottish Education Department. The scheme is welcomed by the Industrial Grants Committee, which considers that, particularly in relation to small firms, these liaison officers should provide a useful complement to the more specialized technical information and advisory services of individual research associations, and it is hoped that in time the officers will materially increase existing contact between industry and research associations. The Committee recognizes that it is important that the research associations should be linked with the activities of the liaison from the outside, and it proposes to consider further how such a full partnership can be fostered. This recognition of the importance of such information work is timely, but it would be even more encouraging to see a keener appreciation of the vital importance in all this of a really adequate system of library and information services for science and technology in all their aspects pervading the Council itself as well as the Advisory Council for Scientific Policy or its successor and the Ministries responsible for science, technology and education.

SOURCE OF CELLULAR ENERGY

The Mitochondrion

Molecular Basis of Structure and Function. By Prof. Albert L. Lehninger. Pp. xx+263. (New York and Amsterdam: W. A. Benjamin, Inc., 1964.) 9.90 dollars.

ALTHOUGH the structures now called mitochondria —a name proposed by Benda in 1898—have been known for more than a century, relatively little progress was made in the investigations of their physiological properties until about 20 years ago. During the 1940's two decisive advances were made. It became possible, by differential centrifugation in special media, to isolate mitochondria from other cell components, thanks to the pioneer work of Bensley, Claude, Hogeboom, Schneider and Palade, without major damage, and in particular without destroying their functional activities. These became thus amenable to detailed investigation on isolation. At about the same time, electron microscopy and its allied techniques such as thin-sectioning made striking advances in the elucidation of the fine-structure of mitochondria. The explosive developments initiated by these new techniques are described, sifted and analysed in *The Mitochondrion: Molecular Basis of Structure and Function*, by Prof. A. L. Lehninger, who himself has been in the forefront of mitochondrial research since 1948.

It soon became established that the mitochondria (and their counterpart in bacteria and certain other unicellular organisms—the 'membrane') are the chief 'power plant' for all cells depending on oxidation as a source of energy. It is the site where the energy of oxidation is released and converted into the utilizable form of high-energy-rich phosphate bonds. In addition, the mitochondria perform several functions, especially transport of ions and water and some chemical syntheses, which involve an expenditure of energy. The design of this power plant, in spite of its tiny dimensions (in rat liver $0{\cdot}1 \times 3\mu$), is of extraordinary complexity. One of the difficulties of analysing this complexity lies in the fact that many of the intramitochondrial chemical processes involve molecules which are embedded in an elaborate fine-structure, not readily accessible to present-day tools of investigations.

Prof. Lehninger's presentation is exceptionally competent. An enormous amount of material has been skilfully sifted and condensed to the essentials. The style is terse, clear and forceful, and the illustrations and diagrams are well chosen. The discussion is lively, directing attention to the gaps and hinting at likely future developments. The aim "to provide a comprehensive guide to current literature" has been splendidly achieved. The book is as up-to-date as any book can be expected to be in these

days of rapid progress: it has been produced in less than seven months.

Prof. Lehninger begins with a succinct account of the historical development of the subject. He then deals with the structural aspects, and this is followed, in several chapters, by a discussion of the oxidative processes (citric acid cycle, fatty acid oxidation and ketone body oxidation and formation, the properties of the electron transport chain and the mechanism of oxidative phosphorylation, including the energetics of mitochondrial metabolism and the control and integration of the various metabolic processes). Other chapters deal with the active transport of ions by mitochondria and with energy-coupled changes of volume and structure. One chapter is devoted to the ultra-structure in which the author discusses the information relevant to bridging the gap between electron microscope and chemical investigations of the basic molecules, or molecule assemblies, which have to be fitted into the structure.

Particularly stimulating is the final chapter on the bio-genesis of mitochondria, a subject on which information is still very scanty. Various hypotheses are discussed and include the *de novo* synthesis of mitochondria from sub-microscopic precursors present in the cytoplasm, the formation from other membranous structures in the cell, and the growth and division of pre-existing mitochondria. Mitochondria certainly have the capacity to synthesize some of their protein from amino-acids. Other mitochondrial components are synthesized extramitochondrially and taken up 'ready made' by the growing (or adapting) mitochondria. But the source of the mitochondrial matrix—the outer cell membrane, the endoplasmatic reticulum, the nuclear membrane, the nucleolus and Golgi apparatus have all been suspected—is still unknown.

The book integrates in a happy way the different kinds of mitochondrial investigations—biochemical, physiological and structural. No doubt it will find many friends among students at all levels. HANS KREBS

TRAINING THE INDUSTRIAL WORKER

Training within the Organization

A Study of Company Policy and Procedures for the Systematic Training of Operators and Supervisors. By David King. Pp. xxii + 274. (London: Tavistock Publications (1959), Ltd., 1964.) 38*s*.

NOW that the State has taken over responsibility for the development of industrial training and has empowered Industrial Training Boards to extract a levy from companies for training purposes, the attention being directed by industry and commerce to training has shown a noticeable increase. Attention, however, is not enough and many industrial managements are finding that the training required of them is much more than the sit-by-him variety. The help of specialists is being increasingly sought and, where they can show a practical approach to methods of training which lead to demonstrable improvements in workers' efficiency, managements are more than ready to accept their recommendations

Training within the Organization aims to provide a systematic approach to the training of operators and supervisors which, so far as it goes, could be most useful to those concerned with the training of operators. King first presents a case-study of a company in Norway which was faced with the need to improve the performance of women employed in garment making. He describes how the elements of jobs were differentiated by analytical methods, how a training sequence and programme were built up, how an instructor was selected and trained, and how the trained novitiates were introduced to the more austere conditions on the factory floor. In a neighbouring factory a similar approach to the training of supervisors led to the setting-up of self-governing working groups.

In the second part of the book the author examines the process of learning and shows how it should be used in training. The third section establishes the place of operator training in the company organization and, in the fourth section, detailed procedures in the training of operators are explained. The author also includes a chapter indicating how the effectiveness of training can be reviewed.

All in all, the case for the systematic training of operators in manual skills is well presented and the book will meet only with the criticism that it contains little that is new and has not been more succinctly presented by others elsewhere. If Mr. King had ventured outside the now familiar training schemes for sewing machinists, garment folders or stocking linkers, his book would have gained wider support, but the narrowness of his approach detracts from the appeal of the book. The inference throughout the whole work is that all that is needed in training operators is improvement in dexterity and that the systematic approach to the inculcation of skills is the universal panacea. The cognitive aspects of an operator's job are almost entirely ignored, and in those jobs where knowledge is at least as important as systematic training to develop manual skills, dexterity could be but a small part of the overall training required. In a chemical plant, for example, or in oil refineries, the operators need not only to be highly skilled manually but also to be well aware of what is taking place in pots and vessels and when and how to read instruments so that manual skills can be properly used. Nor will an approach which is not difficult to introduce on inexpensive equipment like sewing machines offer much comfort to managers faced with the problem of training operators for capital equipment like rolling mills, or for jobs that can only be done by operators working in teams, particularly where complete new teams are seldom required.

Mr. King's exhaustive approach to the development and administration of company training schemes also leaves much to be desired. Rather than detailed procedures, managers and supervisors would welcome guidance about what are, for them, complicated differences between City and Guilds and National Certificate Courses; when and where to recommend operative, craftsman, Intermediate Certificate and full technological courses; differentiation between Higher National Certificates and Higher National Diplomas and what endorsements mean to Section 'C' examinations of the professional institutions. To suggest that operator training schemes can be developed without reference to accompanying educational courses is to take an unrealistic specialist view which implies that we have not progressed far from the concept of the employment of 'hands' in industry.

The attention directed to the training of supervisors is so scanty that it is difficult to understand why it was included. T. H. HAWKINS

ECONOMICS OF EDUCATION

The Control of Education

By John Vaizey. Pp. 263. (London: Faber and Faber, 1963.) 30*s*.

THE Control of Education, the publishers claim, tells us "about education—its value, its cost, its control". In fact, it tells us little about these things but a great deal about Mr. Vaizey's opinions concerning them.

Mr. Vaizey has collected together a number of talks and papers which he has given at various times covering a variety of topics such as "Education and Economic Development"; "Manpower"; "A Policy for Higher Education"; "The Status of Teachers". There has been

very little editing. Since each essay is a unit in itself, it would have been helpful to be told when, and for whom, each had been written. As it is, we are left to grope along a series of dark corridors which turn out to be unconnected.

Some of the content is clearly aimed at developing countries and has little relevance to Great Britain. Much of it concerns education in Britain, but is oddly out of date. Thus, although published in 1963, his chapter on the block grant was presumably written before the introduction of the block-grant system in 1959 and is printed without revision or apology. It repeats the fears expressed by those who then opposed the system and contains no reference to the fact that by 1963 Britain had access to experience of the system as it had been worked out over the first three years of operation. An examination of these years would have shown that Mr. Vaizey's fears prior to 1959 have not been realized; there is, therefore, little point in repeating them as economic laws in 1963.

Mr. Vaizey has earned a deserved reputation as a pioneer of the investigation of the economics of education. Perhaps he is writing too much too quickly. Certainly some of his expressed opinions—including those to which he seems to attach most importance—merit more examination and research than he gives them. It is a good debating point to say that it is the shortage of teachers that keeps the financial structure of education alive. But is it anything more than a debating point ? It is true that to supply the service with the 100,000 additional teachers which it badly needs will cost an extra £300,000,000 a year. But does it follow, as Mr. Vaizey asserts, that had these teachers been available "the local taxation system and the general grant system would have come under intolerable strain some time ago" ? The system is flexible. We already spend £800,000,000 more a year on education than we spent 10 years ago, with no visible signs of a breakdown. Even if there is a ceiling to the rate share of this increase (and we have no idea what it might be), nevertheless the ratio of grants to rates can be adjusted to take the strain.

This is a point which Mr. Vaizey ignores; he seems to cling to the idea that a higher proportion of government grant is inadvisable because it leads inevitably to diminution of local control. This belief that local independence can only be assured by a high degree of local fiscal autonomy used to be widespread, but local authorities themselves are now beginning to question its validity.

Mr. Vaizey, however, not only still holds to this view, he also believes that only a very large authority can pay its way and that the present structure of local government must, therefore, give way to a system of regionalization. This is another *non sequitur*. There is, no doubt, a minimum size of administrative unit necessary for economy and efficiency. But what is this size ? And beyond the minimum, how true is it to say 'the larger the better' ? These are some of the vital questions which the professional educational economists should be considering, but they must be answered on the basis of careful costing, not of pontifical pronouncement.

N. Morris

TOWARDS THE EDUCATION OF THE WHOLE MAN

South Kensington to Robbins

An Account of English Technical and Scientific Education since 1851. By Michael Argles. Pp. xiii+178. (London: Longmans, Green and Co., Ltd., 1964.) 21*s*. net.

South Kensington to Robbins presents the history of scientific and technical education, against its social and economic background, since the Great Exhibition of 1851. In the light of recent developments, and because of the imminent massive expansion in the whole field of technology and technical education, it treats a subject which is interesting, important and timely. The author, the assistant librarian of the University of Lancaster, has produced a first-rate book, which compresses a considerable amount of information into a small space. The documentation is exceptionally well done. He pays tribute to some important figures in the history of English scientific education whose value has never been properly assessed or who have been overlooked. Such men were Albert Prince Consort, Lionel Playfair, Joseph Whitworth, Quintin Hogg (Senior), Roscoe, Lord Percy, A. W. Hofmann and his students. The story of English technical and scientific education, until the Second World War, is both surprising and sad. England did not lack men with knowledge and vision, including some trained in Germany, knowing the position of science and technology there, who were eloquent in their plea for a rational position for the 'pure' and 'applied' sciences in education. In 1851, after the successful conclusion of the Great Exhibition, Playfair said, "Until our schools accept as a living faith that a study of God's works is more fitted to increase the resources of the nation than a study of the Amours of Jupiter or of Venus, our industrial colleagues will make no material headway against those of the Continent". Even the obviously better technical equipment of the Germans at the beginning of the First World War was no lesson to England, so far as education was concerned, and the Spens report of 1938, just before another great war, has to confess that there was "little development of Secondary Schools of quasi-vocational type for those who desired to enter industry and commerce at the age of sixteen".

We have been waiting for Robbins for a number of years and, now that it is with us, we are still waiting, to a large extent, for it in terms of a new Government. But a report, even when followed by the expenditure of large sums of money, does not necessarily secure either success or efficiency. *The Times* considered that "by concentrating on the demand for places, as they interpret it, the members of the Committee have paid too little attention to the difficulties in which the universities would find themselves. The change of scale, the influx of students of questionable academic bent, the thinner spread of first-rate teachers are bound to influence profoundly the nature and quality of British universities . . . the Robbins rate of expansion . . . is not proof against the criticism that it would work to dilute academic standards". The conscientious provincial university teacher struggling with the least apt quartile of his students—"the already tapped sources of untalent"—may well wonder where are the "great untapped sources of talent". It is fair to say that cogent rebuttals of the "more means worse" type of argument have been made.

The foreword to the book is by Charles F. Carter, the Vice-Chancellor of the University of Lancaster. It is a masterpiece in one paragraph. It should be read by every responsible citizen. "Education remains a mysterious process, we are sure neither of how to achieve results, nor of what results we want to achieve. Technical education, though it may seem to have the simple function of providing the developed skills needed by society, must now in reality prepare people to develop skills which have not yet been imagined, required by technical or commercial processes not yet conceived; and it must do this in a way which has regard to the universal need of general education. . . . What we have done has usually been too little and too late; we still have to learn to educate for the needs of the future and not for the needs already passing which we have just belatedly come to understand. There is still a great lack of research and experiment".

Many more teachers who understand and practise modern techniques of teaching, examining and the use of libraries will be required. The university lecture which is a mere transcription of the lecturer's notes into those of the students, without the matter going through the minds of any of them, is not good enough: it never was !

Technology is not enough. It is a means to an end. A better technology does not ease the problems of the starving millions unless it is applied with freedom and goodwill on all sides. It does not even ensure a greater

supply of convenient and cheaper apparatus for better living unless restrictive practices on the part of both employer and employee are removed. If it is largely a matter of John keeping up with Ivan, Jo and Johann in the production of better rockets and aircraft, it has not served its purpose, and may be positively harmful. The development of scientific and technical education cannot be considered *in vacuo*: it must become a harmonious part of the education of the whole man. W. L. SUMNER

SPECIALIZED CONTRIBUTIONS TO PLANT SYSTEMATICS

Recent Researches in Plant Taxonomy

Edited by Dr. W. B. Turrill. (Vistas in Botany, Vol. 4.) (International Series of Monographs on Pure and Applied Biology. Division: Botany, Vol. 7.) Pp. xiii+314. (London and New York: Pergamon Press, 1964.) 105*s*. net.

THE original *Vistas in Botany* was a volume in honour of the bicentenary of the Royal Botanic Gardens, Kew. It appeared in 1959, and was at the same time Volume 2 in an international series of monographs on pure and applied biology. Volume 2 of *Vistas in Botany* was Volume 5 in this same series, and it contained reviews of topics in the general field of economic botany, thus acting as a useful extension of the original volume. Volume 3 was wholly physiological. Volume 4 bears the sub-title *Recent Researches in Plant Taxonomy*.

In view of the contents of the volume, the sub-title is rather misleading, for here are seven articles, essays or comprehensive reviews in which reference to recent research is made in very varying degree. Again, the seven topics, though all in some way connected with the practice of plant taxonomy, are treated so very differently by the different authors that the volume as a whole lacks unity and it is hard to see at exactly what class of reader it is aimed. The present position in flowering plant taxonomy is better stated, and the literature as a whole better covered, in the recent work by Davis and Heywood (*Principles of Angiosperm Taxonomy*), so that the value of the present volume lies rather in the weight of authority with which particular authors of international renown are able to write on their own chosen topics.

The first 22 pages are occupied by an article on philosophy and classification by J. S. L. Gilmour and S. M. Walters. In this perspicacious and scholarly article there is plenty of food for thought, but its content does not range far beyond what may be found in earlier contributions by one or other of these authors. The second chapter, of similar length, is that of Prof. G. Erdtman on palynology. Its effect is to leave one conscious of the almost excessively detailed examination to which pollen grains have been exposed in recent years. While such items as the tables on pp. 28 and 29 afford a useful summary of information, the figure on p. 31 will incline most botanists to leave pollen grains strictly to the specialists. For the few, the minute detail will provide a fascinating challenge, and they will be attracted both by Prof. Erdtman's clear exposition and by the technical brilliance of his illustrations.

Embryology in relation to taxonomy, by Prof. P. Maheshwari, occupies 43 pages and is an excellent summary of a subject which does not always receive the attention it deserves from taxonomists. This chapter is superbly illustrated and concludes with a bibliography of 167 references. These features, together with the clear presentation of the selected facts, make it a most valuable part of the book.

The next 87 pages are occupied by what is not only by far the longest chapter in the book but also the one that is, both from the technical and linguistic points of view, the most difficult. One feels that "Cytologie, Taxonomie, und Evolution bei Samenpflanzen", by Dr. F. Ehrendorfer, will appeal only to comparative specialists already well acquainted with this subject and anxious to read Dr. Ehrendorfer's authoritative views on it. The 21 figures are not uniformly easy for a student to grasp, but the bibliography of 346 titles should be useful.

There follow two chapters by the late Dr. W. B. Turrill, one of 37 pages on "Plant Taxonomy, Phytogeography and Plant Ecology", the other, of 13 pages only, on "Floras". Both suffer from excessive use of generalized statements. To trace the delicate interconnexions between taxonomy, phytogeography and ecology is no easy task; and somehow the article fails to achieve this aim. The arbitrary fragmentation of the subject into 'bits' does not help, and it is hard to see how 'types and typology' or 'herbarium problems' bear directly on the topic under review. At times a combative attitude obtrudes and there is some needless repetition. Much of the very sketchy chapter on "Floras" is self-evident and seems to be aimed at an entirely different class of reader from those visualized in the earlier contributions.

The final chapter on fossil plant taxonomy, by Dr. K. I. M. Chesters, is a most readable summary of a wide range of palæobotanical work. It will be useful to many non-specialist readers, but would have benefited greatly by illustrations on the liberal scale provided by Prof. Maheshwari.

The book is pleasantly produced, but better proof-reading would have eliminated numerous imperfections. Some are misprints, such as "micropore mother cells", "dabatable", "suported" and "phyllum" (phylum); others are examples of unfortunate phrasing such as "in the degree that" on p. 188, or confused construction where a sentence is left with no main verb, as on pp. 271 and 277. One finds the use of "globulets" for globules, "millenni" for millennia (p. 199) and "petrification" for petrifaction (p. 261) annoying, but "climate vegetation" in place of climax vegetation (p. 198) and "rhizomorph" for rhizophore (p. 265) are more serious. "Subdividable" for divisible and "analogical" for analogous are further verbal atrocities which ought not to have been allowed to mar a book of this class. With well under 300 pages of reading matter the book is a little expensive at five guineas.

E. V. WATSON

A WREATH FOR THE ENGLISH BOTANISTS

Sertum Anglicum, 1788

By Charles-Louis L'Héritier de Brutelle. Facsimile with Critical Studies and a Translation. (The Hunt Facsimile Series, No. 1.) Pp. xcviii+36+34 plates+12. (Pittsburgh: The Hunt Botanical Library, Carnegie Institute of Technology, 1963.) n.p.

NO one, however charitable, can honestly maintain that Charles-Louis L'Héritier, Seigneur de Brutelle, has any particular claim to fame as a botanist. He was at most a competent disciple of Linnaeus, content to elaborate and augment the works of his master at a time when many of his more enlightened compatriots were following the banner of de Jussieu away from the rather sterile formalities of the sexual system.

L'Héritier's few, and generally incomplete, publications are valued as rarities; they are, for the most part, of grand dimensions and amply illustrated by exceptionally gifted artists; they also happen to contain the first published identifications, descriptions and figures of a number of plants, some of them now well known to others besides taxonomists. For these reasons a facsimile edition of the rare (and incomplete) *Sertum Anglicum* is to be welcomed, indeed doubly welcomed, because the Advisory

Committee of the Hunt Botanical Library (sponsoring the publication) has had the good sense to make room for several valuable introductory essays, including a masterly biographical and bibliographical account of L'Héritier's life and works by Dr. F. A. Stafleu. Anyone who has ever had the misfortune to be involved in the nightmarish task of trying to date L'Héritier's publications will be eternally grateful to Dr. Stafleu for his researches; and those who have pondered on the character of the man who could perpetrate such bibliographical horrors will find illumination in the biography.

L'Héritier may have been a praiseworthy magistrate, but as a personality he was the type specimen of an exasperating and not uncommon species—devious, secretive and, as de Candolle remarked, "avec une sorte de complaisance aux petites intrigues". Sir Joseph Banks was caught up in the network of "petites intrigues" almost as soon as the misguided L'Héritier landed at Dover, and at once erupted in full fury: "Of all the impudent Frenchmen in the whole world he is the most impertinent and dangerous". But L'Héritier, with the pertinacity characteristic of his breed, survived the eruption, and more than eight months later, in May 1787, was still visiting Soho Square, and Banks was writing, somewhat wearily, "L'Héritier is still here to the amazement of everyone and has given no signs of an intention of returning. He has left off working at Dombey's Herbarium some time and now runs most diligently from garden to garden, buying plants in profusion and books without end".

Banks was to suffer his persistent visitor for a further six months, and, to crown his discomfiture, was to receive, in January 1789, the first fascicle of the *Sertum Anglicum*, dedicated to the English botanists, and recalling "how courteously everyone received me; how the scholars showed themselves accommodating and ready to reveal their treasures; how especially the men so learned in botany assisted me obligingly". Poor, poor Sir Joseph!

And poor, poor L'Héritier! His fate was tragic in excess of his deserts. But this lurid and mysterious story lies far beyond the scope of a review.

R. D. Meikle

AUSTRALIAN GRASSLAND RESEARCH

Grasses and Grasslands

Edited by C. Barnard. Pp. viii+269. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1964.) 50*s*.

THE subject of this book has received attention by research teams in many countries, and Australian scientists have made major contributions in this field. It is pleasing therefore to have the Australian findings relating to grasses and their utilization brought together under one cover. This is done within the context of much basic knowledge concerning the biology of the grasses, a necessary preliminary to their proper use as agricultural plants. There are fourteen chapters, written by present and past members of the staff of the Division of Plant Industry in Canberra.

The volume is therefore a series of specialist essays giving a mass of detailed information on a number of subjects. Each is more or less complete in itself, but there is perhaps insufficient cross-reference. The chapters are well documented, each with its own extensive list of references; many are annotated by diagrams and photographs, some depicting plant parts and others a range of grassland types belonging to the Australian environment.

The first chapter deals with historical aspects of grass and grassland development. It indicates also the relationship between grass and the grazing animal. This affords a useful introduction in which reference is made to agronomic sequences and also to the importance of grasslands in the agricultural economy. The next nine chapters are concerned with the biology of grasses, their taxonomy, distribution, morphology, histology, physiology of growth and reproduction, and with cytogenetics and plant breeding. Whereas the range limits of grass species may be determined by climate, distribution is greatly affected by agricultural influences. The distribution of grasses offers an index of the whole environment, but this probably holds more widely and in other families.

Grasslands as plant communities are considered in four separate chapters dealing respectively with distribution, nutrition, animal influence and soil conservation. The parts played by climate, topography, the biotic factor and fire are described as factors in grassland ecology. The nature of climax is noted and it is suggested that the mono-climax theory is untenable because climate is not the sole factor which determines the distribution and type of grassland.

The supply of soil nutrients has an important influence on the composition and production of pastures. Grassland improvement in Australia is much concerned with the legume, and emphasis is placed on the legume/grass relationship. Grazing management is discussed in relation to different grassland groups in Australia, where the trend on mesophytic grasslands has been towards winter-growing species and introduced annuals, a trend much influenced by the use of subterranean clover. There is, however, much to commend the perennial as the dominant constituent of pasture land. In arid situations some of the changes which follow grazing are harmful to pastoral production, and modified patterns of grazing are required. This matter needs emphasis, for in many countries grassland management is a most important factor in determining pasture type. Grazing may be too lenient, but more often harm is done because of over-pressure by animals.

Management has the dual purpose of providing animal feed and maintaining a protective cover on the soil. Soil conservation is basically the correct use of land, but we need to know how different swards behave as soil covers, especially at periods of stress when the sward may be open and under much grazing pressure. Stocking rates may have to be adjusted to meet this situation to minimize loss of soil.

The book is well produced, and the text reasonably free from minor error (the name of one author is omitted from the list of contributors, however). The subject is important, and the volume should prove of lasting value to a wide audience with an interest in grasses and grassland in general.

W. Davies

FORMOSAN FOREST FLORA

Woody Flora of Taiwan

By Hui-Lin Li. (A Morris Arboretum Monograph.) Pp. x+974. (Philadelphia, Pa.: The Morris Arboretum; Narberth, Pa.: Livingston Publishing Company, 1963.) 18.75 dollars.

THIS well-presented and attractive volume is divided into two unequal parts, a short introduction and a much bulkier systematic treatment of the woody plants of Taiwan. The introduction gives short accounts of the physical features of Taiwan and of its vegetation, including a brief history of botanical collecting and a very short review of its forestry. An analysis of the geographical affinities of the Taiwan woody flora is included. These turn out to be strongest with Eastern Asia, such elements (on the species level) comprising some 40 per cent of it, as might be expected for this Island province only 140 km offshore of the Asian land-mass. Of the rest, 25 per cent consists of various tropical elements and some 35 per cent is considered, in this account, to be endemic. This seems a remarkably high figure, and one wonders

how it would stand up to a more thorough comparison of the flora with that of mainland China, and to thorough monographic revision of the genera, especially the tropical ones.

The floristic part proper consists of a systematic descriptive account of the woody plants of Taiwan, arranged under families on the Englerian system but with the few monocotyledons at the end. Unfortunately, no indication of the author's criteria on which a plant is admitted, as woody, to this Flora is given; that there are many borderline species which are often variable in their habit is well known. The treatment claims to be a critical one, as indeed it should be, for time and money spent on those that are not so are, for tropical and sub-tropical areas at least, time and money wasted. Within the limitations of its size and format it does give quite full keys, descriptions, and citations of places of original publication of names and synonyms, and of herbarium specimens. These latter are of particular value in illustrating the author's taxonomic conclusions. Nevertheless, the work shows some disquieting features. It includes a number of incorrect names and erroneous citations, and at least one invalidly published name; while some names recorded for the Taiwan flora have not been accounted for. Furthermore, some of the more recent monographic work that has concerned, in part, the Taiwan flora (especially its tropical elements) seems to have been overlooked, and some of the literature cited appears not to have been personally checked by the author. Thus the book does not inspire confidence as a source of basic taxonomic data for the working taxonomist. To botanists in general, however, it will be welcome as a source-book of information on the woody plants of Taiwan.

As it is a woody flora its interest to the forester must also be considered. The main purpose of a Flora of any region must surely be to enable anyone who is not a taxonomist to determine as reliably and as easily as possible the correct name of any plant he finds growing in that region, and to give such references to synonymy and literature, as to enable him to pursue further information on it should he so require. Judged on these considerations, this Flora does quite well on the second count but not so well on the first. It omits virtually all introduced species; foresters familiar with the wanderings of many conifers and eucalypts will realize the limitations this imposes. There are numerous more or less satisfactory line-drawings, but these seem to have been made mostly from herbarium specimens—there are no photographs to show such field characters as bark type or shape of crown, nor is there any mention of them, or of vernacular names, in the text.

But in the final analysis a Flora stands or falls by the quality of its keys. Those in this book may or may not be reliable, use and time alone will tell, but they are not easy to use. The characters used are often quite needlessly difficult technical ones, and there is no glossary, nor any diagrams, to explain terms that are used. The Chinese forester may well find the difficulties of this entirely English text insurmountable. There are also some errors in the keys, for example, a whole line that should read "3. Ovary of a single carpel", has been omitted below the second lead of couplet 2 on p. 27, while on p. 159 the key characters of *Schisandra* and *Kadsura* have been transposed.

One is left with the impression that this book falls between two stools, being insufficiently rigorous, detailed and thorough in its taxonomic approach to serve as an authoritative regional Flora, nor, on the other hand, is it sufficiently suited to the needs of the local forester to be considered as a working forest Flora. It does, however, bring to the notice of botanists in general, and students of the Taiwan flora in particular, the richness of the Formosan woody flora, and, to the latter, their good fortune in having at hand such a wealth and diversity of the raw materials of botany.

C. JEFFREY

PLANT AND ANIMAL COMMUNITIES OF BRITAIN'S ROCKY SHORES

The Ecology of Rocky Shores

By Dr. J. R. Lewis. Pp. xi+323 (40 plates). (London: The English Universities Press, Ltd., 1964.) 42*s*. net.

THERE is now an impressive literature on intertidal life. Beginning in the eighteenth century, flourishing exceedingly in the mid-Victorian days of Philip Henry Gosse, during this century interest has spread to all the shores of the World. The great surveys of Australian, South African and North American rocky shores by T. A. Stephenson represent major enquiries into the distribution of animals and plants. They also revealed the universal presence of three horizontal zones he termed supralittoral fringe, midlittoral zone and infralittoral (or sublittoral) fringe, each delimited not by any fixed position in relation to tidal levels but by distribution of certain indicator species.

On the basis of his own investigations, initiated under T. A. Stephenson, which have taken him from the shores of western Ireland to those of Caithness, together with those of others concerned with specific aspects of the many problems involved, Dr. Lewis has produced what is reasonably described on the cover as "the first comprehensive account to be published of the dominant plant and animal communities of the rocky shores of the British Isles". The book is admirably produced with excellent photographs and diagrams, stylized representations of zonation, and a most useful systematic index.

Dr. Lewis prefers to divide shores into a littoral fringe with an upper limit of *Littorina* and *Verrucaria* (lichen), a eulittoral zone separated from it by the upper limit of barnacles (the two constituting the littoral zone) and a sublittoral zone bounded by the upper limit of *Laminaria*. The height to which each extends and the width it attains become greater with increased exposure. This is immediately demonstrated in an introductory comparison between a fully exposed shore at Parkmore Point, Co. Kerry, and an extremely sheltered one within Clachan Sound, Argyll.

Consideration is then given to factors influencing zonation—tides, exposure (all-important and yet measurable only by subjective criteria), topography and substratum, climate, time of low water of spring tides and presence of other organisms—and then to those influencing the geographical and local distribution of shore species. The next two parts of the book are devoted to descriptions of zonation, first on open coasts, with separate consideration of the eulittoral areas dominated by barnacles, by mussels and by Fucaceae, and then in lochs and very sheltered bays. The concluding chapters are devoted to the consideration of the many problems that present themselves.

Precisely why should a species disappear as a headland is rounded? Is this due to inability to settle or, having done so, to maintain or reproduce itself? Why should mussels occur on some eulittoral shores and barnacles on others, apparently similar? Why is it impossible to predict what exact combination of an invariable assemblage of sponges, hydroids, polyzoans and ascidians will occur in any region of tidal rapids? Anomalies abound, and the clearer the general picture the more obscure become its details. But part of the answer, as Dr. Lewis notes, is that shore populations are always changing, young individuals replacing old ones, new populations settling from the plankton and with all manner of intermittent, seasonal and perhaps purely chance factors exerting their separate or interlocking effects. There is on the shore no inevitable succession leading to a stable climax.

The most specialized and successful shore animals are the acorn barnacles, which are of exceptional interest on British shores. There is the overlap in the eulittoral of the northern *Balanus balanoides* and the southern *Chthamalus*

stellatus, each with its own ecological requirements, the latter generally demanding greater exposure and extending higher. Where they overlap the two species in some places compete, in others occupy distinct zones indicating other controlling factors. Nor is distribution static; the two follow the present general northward trend of marine populations. Added to these is the Australasian *Elminius modestus* the spread of which since 1945 has been so carefully followed. Here other ecological needs, structural limitations and more frequent reproduction, have all to be considered.

All is admirably dealt with and, if Dr. Lewis does in places labour somewhat too desperately for exact description and explanation, he does in text, photograph and diagram convey an impression of the richness and variety of intertidal life on Britain's rocky shores which will come as a revelation to many and be of the greatest value to all who study these shores. This book is a major addition to knowledge concerning the fauna and flora of these islands.

C. M. Yonge

BIRDS OF THE AMERICAS

Birds of the Labrador Peninsula and Adjacent Areas

A Distributional List. By W. E. Clyde Todd. Pp. xii + 819 + 8 plates. (Toronto: University of Toronto Press; London: Oxford University Press, 1963. Published in association with Carnegie Museum.) 18 dollars; 144*s*. net.

The Birds of Colombia and Adjacent Areas of South and Central America

By R. Meyer de Schauensee. Pp. xvi + 427 (20 plates). (Narberth, Pennsylvania: Livingston Publishing Company, 1964.) 10.00 dollars.

EACH of these books deals with the avifauna of a particular area in the New World, one sub-arctic, the other tropical; both are products of the expeditionary enterprises of museums in, as it happens, Pennsylvania. There the resemblance ends. The work on Labrador is purely a research report, with the limited scope indicated by its sub-title. The other is a dual-purpose book, presenting the results of research in summary form and at the same time serving as a guide to the identification of the birds to be found in Colombia and adjacent areas.

Clyde Todd is indeed a veteran worker, having entered on his career as a professional ornithologist in 1891. This has been mainly associated with the Carnegie Museum in Pittsburgh, where he now has the status of curator emeritus of birds. From there, in the period 1901–58, he organized 25 ornithological expeditions to Labrador; most of these he led in person, and occasionally he was single-handed. The object was to study the distribution of the bird species found in that inhospitable area, and the existence of such 'life-zones' as climatic and physiographic factors could be shown to determine.

The result of these prolonged and arduous investigations has been a massive accumulation of detail, all this time deliberately withheld from publication. The information is now presented in its entirety, and fully documented with references to other sources; it makes a volume of outsize dimensions and more than 6 lb. in weight. Inevitably, it is strictly a work of reference.

Meyer de Schauensee is curator of ornithology at the Academy of Natural Sciences of Philadelphia, where he and various colleagues have made special investigations of the immensely rich bird-life of Colombia. As a work of reference his book usefully summarizes what is known about the distribution of species and sub-species in Colombia, with indications of the wider range. It is, however, designed primarily as a handbook, and is accordingly provided with descriptions to aid identification and with numerous illustrations both in colour and in line; habits are mentioned only briefly, in the general introduction to the systematic treatment of each family. It is an attractive volume, admirably adapted to its purpose.

The work has much more than a local relevance, and its appearance is particularly to be welcomed because, as the author puts it, "no modern book exists in English on tropical birds of continental South America". In these circumstances the book will be very useful beyond the confines of Colombia itself; it covers three-fourths of the birds found in a much larger adjacent area, and more than half of those found in the tropics of Central and South America from Yucatan to Paraguay.

It is interesting to contrast the two areas. In Labrador there are only 49 species or sub-species that are found throughout the year, with 4 others that are winter visitors from further north; 200 are breeding summer visitors, and 34 others (excluding 'accidentals') are migratory transients or non-breeding summer visitors. The total compares with 1,556 species (2,640 sub-species) recorded from Colombia—a figure without known parallel. This is a sign not only of the richness of the tropics, and of the neotropical region in particular, but also of the great diversity of the country; Colombia has coasts to the Caribbean and the Pacific, parts of the Orinoco and Amazon systems, grassy plains, continuous forests, and mountains rising above the snow-line to 19,000 ft.

Landsborough Thomson

CARPENTRY TOOLS

The History of Woodworking Tools

By W. L. Goodman. Pp. 208. (London: G. Bell and Sons, Ltd., 1964.) 45*s*. net.

THE History of Woodworking Tools provides the first comprehensive account of such tools in the Western hemisphere. It seems surprising that objects which play such a vital part in everyday life have not been more often investigated but, as Mr. Goodman points out, there seems to be a general impression that through the ages there has been very little change in the form of the more common tools. He goes on to suggest that this is not the case, but that in almost every detail of their design and construction, changes and improvements have occurred.

Woodworking tools are described in this book under eight headings, starting with the axe and adze. The earliest of these were the antler axes, used by small groups of people living in Denmark in the Mesolithic period. Axes and adzes of flint and stone followed, hafted in various ways, and then a variety of tools in bronze, iron and steel, some of them very specialized forms.

The origin and development of the plane are not so clear. The Greeks had a word for it, but the earliest examples are Roman, and numerous fragments survive from this period as well as representations carved on tombstones. The old belief that this tool was forgotten in the Dark Ages and re-invented in the twelfth and thirteenth centuries is disproved by new evidence from Frisia and Anglo-Saxon England. Few tools of any kind of the period from 800 until 1600 survive, but there is much pictorial evidence, sometimes puzzling or obviously inaccurate, according to the interest taken by the artist in practical matters. In this context, the building of Noah's Ark is often a fruitful subject for contemplation. From 1600 until the present day there is abundant material. Indeed, the two centuries after 1600 are described as the 'Golden Age' of woodwork, because the rising standard of living and the appearance of new types of wood from the New World and the Far East demanded increasing skill from joiners and cabinet-makers, and a wide range of special tools.

The first true saws seem to date back to the early Bronze Age, although flint knives with a serrated edge go back to earlier times. The saws were made of copper, and the arrangement of the teeth shows that they must have been used with a pulling action. The far more effective saw with

a pushing stroke must have been developed by the Romans, who understood the importance of setting the teeth. They also experimented with an extension of the handle along the top of the blade, thus anticipating modern backed saws, and developed several types of framed saw in various sizes which continued in use through the Middle Ages until the present day in some backward areas.

Boring tools include the bow-drill depicted on early Egyptian reliefs, the auger used by the Romans, and the brace, known as a fully developed tool in northern Europe in the fifteenth century and probably originating farther east. Chisels and gouges, which date back to prehistoric times, have a section to themselves. Other essential items of the carpenter's equipment are also discussed and include his bench, also probably a Roman innovation connected with the invention of the plane, devices for measuring and setting out, such as rulers and dividers, squares and levels, and even his bag.

The book is attractively produced and well illustrated, with 200 photographs or line drawings of both actual tools, and tools shown in pictures, illustrated books, sculpture or wood-carvings from all over Europe. Many of the objects depicted, such as the seventeenth- and eighteenth-century planes, show much decoration, so that Mr. Goodman has not only produced a useful work of reference for craftsmen, but also an important book for all who are interested in the ordinary every-day life of people at all periods.

JOAN LIVERSIDGE

INTERNATIONAL SPACE RESEARCH

Space Research IV

Proceedings of the International Space Science Symposium, Warsaw, June 4–10, 1963. Edited by P. Muller. (Organized by the Committee on Space Research—Cospar —and the Polish Academy of Sciences.) Pp. xvi + 997. (Amsterdam: North-Holland Publishing Company, 1964.) 220*s*.

THE fourth International Space Science Symposium arranged by the Committee on Space Research (COSPAR) was held at Warsaw in June 1963, and, as in previous years, the proceedings have been published in a handsome 1,000-page volume by the North-Holland Publishing Company. The papers are mainly concerned with geophysics and interplanetary physics—with Earth, Air, Sun and Space. There is little on the tracking or dynamics of satellites, while the biological papers are being published in a separate volume.

Since the subject-matter of space physics extends without interruption from cloud-level to the outermost limits of the universe, any attempt to classify the papers is liable to be as fallacious as librarians' attempts to classify books. But in both spheres the attempt must be made, and in the present volume the division into, basically, six sections is surprisingly successful. There are 90 specialized papers in the six sections, and it is worth mentioning a few individually, even though others equally worthy must be omitted.

The first section deals with the upper atmosphere, which in practice means the study of the main neutral constituents of the atmosphere from the stratosphere to about 2,000 km height. L. G. Jacchia and J. Slowey report the most detailed analysis yet made of the variations in upper-atmosphere density and temperature at heights near 600 km, from the orbit of the *Explorer* 9 satellite. K. Y. Kondratyev discusses how to interpret the measurements of the Earth's outgoing radiation made by meteorological satellites.

The next section is on the ionosphere, which is to be interpreted as the charged particles with ordinary thermal energies at heights from 100 to 2,000 km, and sometimes higher. R. C. Sagalyn and M. Smiddy report on the electrical microstructure of the *D* and *E* ionospheric regions. The measurements of electron density made (by different methods) from the *Alouette* and *Ariel* 1 satellites are described by G. L. Nelms and P. Rothwell respectively.

The third section, entitled "Magnetosphere", is primarily concerned with the high-energy trapped particles of the radiation zones at heights ranging from 400 km (near the Brazilian magnetic anomaly) up to the outer limits of the Earth's atmosphere, 50,000 km or more. There are three papers, by Yu. I. Galperin, V. I. Krassovsky and others, on the results from the *Cosmos* 3 and 5 satellites, while L. A. Frank, J. W. Freeman, jun., and J. A. Van Allen describe their mapping of the outer boundary of the magnetosphere with the aid of *Explorers* 12 and 14.

The fourth section describes investigations of solar radiation, chiefly ultra-violet and X-ray, and includes many new measurements from the *Oso* 1 and *Ariel* 1 satellites, and from high-altitude rockets. The fifth section is devoted to the interplanetary medium (the plasma streams and meteoric material). There are useful papers by T. Obayashi and E. I. Mogilevsky on the interaction of the solar wind with the Earth's magnetosphere, and by T. R. Kaiser and C. T. D'Aiutolo on meteoric particles. Finally, there is a group of papers on cosmic rays, X-rays and nuclear reactions in space.

The specialized papers are preceded by a valuable series of review papers. The first, a frankly critical review of the ionospheric *F*-region by J. A. Ratcliffe, offers a new method of presenting a scientific paper, as the bare bones without the all-too-solid flesh of verbiage which normally hides them. Though some readers may yearn for more complete sentences, this vivid staccato style may well be more conducive to progress than the stodgy tone of the average scientific paper, because it brings out the main points at issue so clearly. The dozens of unanswered quickfire questions inevitably give the impression, however, that little has been discovered in thirty years of ionospheric investigations.

There are two important review papers on the aurora and airglow by B. J. O'Brien and V. I. Krassovsky. O'Brien notes that the energy required to run the world-wide aurora is on average 4×10^{17} ergs/sec, while the tube of particles streaming out from the Sun, as intercepted by the outermost atmosphere, brings about 3×10^{19} ergs/sec. So 1 per cent of the solar-wind energy could sustain the aurora. But the detailed process—the life-history of the particles—is still unknown.

P. V. Vakulov and others contribute a thorough review of cosmic rays, their energy spectra and their time variations, utilizing measurements both in space probes and on the ground. W. N. Hess discusses the life-times and life-histories of high-energy particles trapped in the radiation zones, and there is a useful review by E. R. Mustel of the Sun and the interplanetary plasma. C. W. Snyder and M. Neugebauer contribute an interesting report on the measurements of the solar wind made by *Mariner* 2, which showed that the velocity of the plasma varied between 300 and 800 km/sec, with a 27-day recurrence tendency and a mean of about 500 km/sec.

The book, like its predecessors, is well printed and produced, with good type and paper, though misprints are more frequent than in previous volumes. Each of the papers is intended to have abstracts in English and Russian, but many of the Russian ones are unfortunately missing. Several of the Russian papers are rather difficult to read because the English is far from fluent: most specialists will be prepared to accept this slight inconvenience as a small price to pay for the advantage of having so many Russian papers available in English within a year of the conference. Recording as it does the main advances in space research, reported by the leading space scientists of all countries, this volume should be in every library covering the subject, and many space scientists will wish to obtain a personal copy for reference.

D. G. KING-HELE

Georges Cuvier

Zoologist—a Study in the History of Evolution Theory. By William Coleman. Pp. x+212. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1964.) 40*s*. net.

THE life of Cuvier is a 'success' story, a rise from provincial obscurity to eminence as an imperial inspector of public instruction under Napoleon and peer of the realm under the restored Bourbons. It is also a record of sustained, highly organized and immensely productive enquiry into the structure of animals. "Dissection and description," in the words of Mr. Coleman, "could produce the clear and indisputable facts, and comparison could generalize them and reveal their real significance. The principal generalizations thus formed were the famous anatomical rules: the correlation of parts, which established the interrelated physiological operations and morphological features which guaranteed the life and integrity of the organism, and the subordination of characters, which determined the taxonomic value of the structures making up the organism."

After Aristotle, whom he held in profound respect and whose teleological attitude he endorsed, Cuvier is the supreme comparative anatomist. His contributions to classification (as distinct from taxonomy) are profound; the principles underlying the modern subdivisions of the animal kingdom spring directly from the criteria on which he based establishment of his four *embranchements*. Belief in special creation, based on scientific rather than religious belief, did not prevent investigation of fossils, to the reconstruction of which he applied the pregnant conception of the correlation of parts. The first true palæontologist, he nowhere contemplated a succession of species with extinct forms providing evidence of progressive advance. He thought only of a series of populations successively eliminated by catastrophes.

Opposing with equal vigour the evolutionary ideas of Lamarck and the concept of the archetype propounded by the German *Naturphilosophen* and so ardently championed by his other great contemporary, Etienne Geoffroy St. Hilaire, Cuvier has more in common with Linnæus. Both sought, the latter in the *Systema Naturae* and the former in the *Régne animal*, to lay bare the plan of creation. Failing inevitably in this, they nevertheless, by establishment of the species concept and by clear demonstration of structural relationships, laid firm foundations for later establishment of the fact of evolution.

In this concisely written book, Mr. Coleman has not attempted a life of Cuvier with its public triumphs and private tragedies. He confines himself to an analysis of ideas contained in Cuvier's unpublished as well as his published work, and in so doing provides an important contribution to the history of zoological thought.

C. M. Yonge

Iconographia Mycologica, VIII

By O. Verona and T. Benedek. (Mycopathologia et Mycologia Applicata, Vol. XVIII, Supplementum.) Pp. iv+plates *A*166–181, *B*52–65, *C*106–115, *D*30–39. (Den Haag: Uitgeverij Dr. W. Junk, 1962.) n.p.

Iconographia Mycologica, IX

By O. Verona and T. Benedek. (Mycopathologia et Mycologia Applicata, Vol. XIX, Supplementum.) Pp. iv+plates *A*182–203, *B*66–73, *C*116–135. (Den Haag: Uitgeverij Dr. W. Junk, 1963.) n.p.

Iconographia Mycologica, X

By O. Verona and T. Benedek. (Mycopathologia et Mycologia Applicata, Vol. XX, Supplementum.) (Den Haag: Uitgeverij Dr. W. Junk, 1963.) n.p.

THIS series of unbound plates, 50 to a volume, offers clear line drawings to illustrate the genera of microfungi. Usually only one species is figured, occasionally a small genus is treated in greater detail; for *Fusoma* Corda, Plate *A*169, no species is named, though conidia and conidiophores are drawn.

The scope of the work is very wide, covering every group of fungi from the lower Phycomycetes to the Uredinales, a field too vast for any modern specialist. Hence, in the chaotic state of fungus systematics, the authors must expect serious problems in the interpretation and typification of some generic names. They are not well-known taxonomic mycologists, and their work would have greater authority if the source of each plate were clearly stated. At present one is left to guess how much is original, how much copied and from which source. When, as with *Englerulaster macowanianus* (Plate *C*114), for example, a figure is attributed to a standard authority, it may be found to have been somewhat drastically redrawn. This plate is taken from Arnaud, but that next to it, *Morenoella mollinediae* (*C*113), is not clearly so attributed, though he is cited as authority for the genus. Comparison with Arnaud's Pl. XXI shows the lower part of *C*113 to be copied closely from his work and the remaining portions to be apparently inspired by him, but they are so modified that direct borrowing cannot be demonstrated.

A brief description accompanies each plate. The book is in English, sometimes not happily worded, and the proof-reading leaves something to be desired. For example, on p. *D*38 we read: "*Schizonella* parasitizes Ciferaceae" and, under *Cintractia*, "living on Ciperaceae"; in each case 'Cyperaceae' is intended. This would appear to be a work which could fill a useful role for mycologists who lack access to an adequate library, but which would profit by more critical taxonomic supervision.

R. W. G. Dennis

The Annual Species of *Medicago*

By Chaia Clara Heyn. (Scripta Hierosolymitana, Vol. 12.) Pp. 154. (Jerusalem: At the Magnes Press, The Hebrew University; London: Oxford University Press, 1963.) 36*s*. net.

SOME genera seem to have been designed by Nature to defeat the plans of botanists; some re-planned by botanists to obscure the designs of Nature. *Medicago* has had the worst of both worlds, the natural intricacies of its taxonomy being further confused by the complexities of its nomenclature. Fortunately Dr. Heyn has appeared, like a botanical Ariadne, offering guidance through the labyrinth, and showing us that the way, though tortuous enough, is not insuperably perplexing.

The revision is restricted to the annual members of the genus, and includes full descriptions and synonymy of 28 species and 35 varieties, supplemented by keys and a generous number of really excellent illustrations, photographs and text diagrams. Notes on habitat and geographical distribution, and lists of specimens examined, accompany the description of each species and variety, and where the author feels the need for further elucidation there are explanatory notes on taxonomy and nomenclature. All this information, together with a readable introduction and a good bibliography, will come as a boon, not only to professional taxonomists, but to all those agriculturists and plant-breeders who have hitherto struggled with this intractable genus.

Dr. Heyn has had the good luck to live in a country where it is possible to examine living specimens of most of the species she describes; it is gratifying to add that she has taken full advantage of her situation, and provided us with a revision which will be of lasting value. Only very occasionally, as in the treatment of *Medicago aculeata* and its varieties, or in the comments on the typification of the genus *Medicago*, does one venture to question her conclusions, and, in such a labyrinth, it would surely be unreasonable to expect that our guide should never once falter or stumble.

R. D. Meikle

RADIO ECHO SOUNDING THROUGH AN ICE SHELF

By M. E. R. WALFORD

British Antarctic Survey and Scott Polar Research Institute, Cambridge

IN December 1963 a tractor journey of 200 miles was made on the Brunt Ice Shelf from the British Antarctic Survey base at Halley Bay (Base *Z*, 75° 31′ S., 26° 40′ W.) and some unexpected results were obtained with a radar instrument developed for the penetration of polar ice masses. They seem to be different from the observations made by Waite (private communication) with a higher frequency apparatus on the Ross Ice Shelf. The techniques have been described by Evans[1] and the important parameters of the present apparatus are given in Table 1.

The range of a radar target is indicated by the echo delay-time, with an accuracy determined mainly by the rise time of the receiver. The shortest measurable range is limited by the recovery time of the receiver after the transmitter pulse and in practice, by echoes from nearby surfaces, probably stratifications in the snow. The aerials can be seen in Fig. 1: they transmit and receive most power in their equatorial plane, which includes the vertical and the direction of travel. Due to refraction, the sensitivity in the ice is greatly reduced beyond 35° to the vertical. There is no other means provided

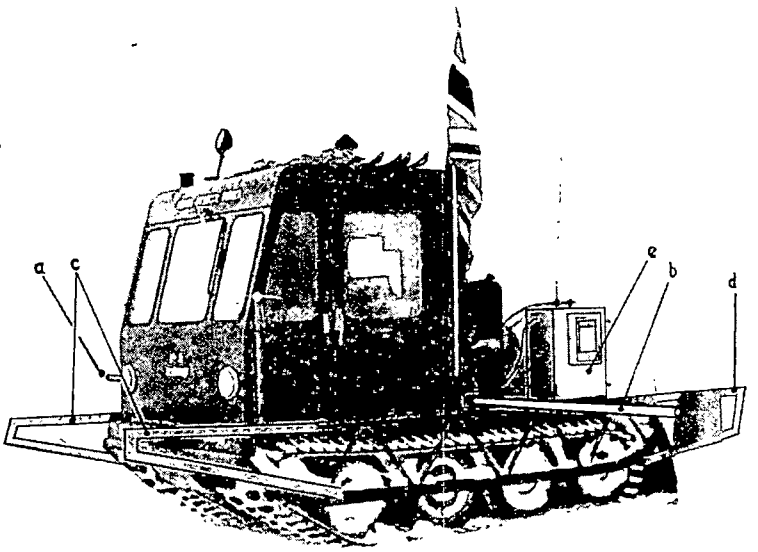

Fig. 1. Muskeg vehicle with separate unipole aerials (*a*, *b*) for transmission and reception. The 'Dexion' extensions (*c*, *d*), which increased the effective electrical length of the vehicle, were found necessary to reduce the direct coupling between transmitting and receiving aerials and to provide correct electrical loading. The box (*e*) contains the electronic equipment except for a display unit mounted in the vehicle cab

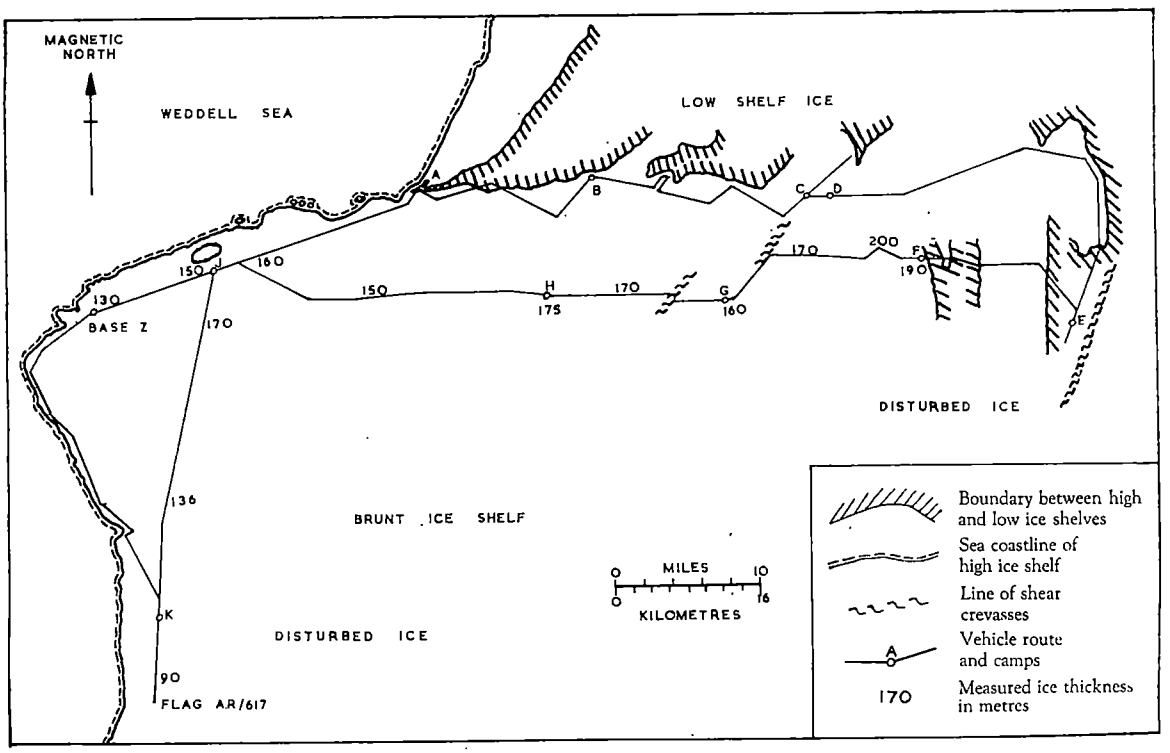

Fig. 2. Sketch map (after Finlayson, British Antarctic Survey Sledging Report, 1963) showing the vehicle route on the Brunt Ice Shelf. Base *Z*, Halley Bay, has Geographic co-ordinates 75° 31′ S, 26° 40′ W.; the magnetic deviation is 1·7° west of true north. Results obtained between Base *Z* and Camp *F* and between Camp *J* and Flag *AR*617 are plotted in Fig. 3. Most of the ice shelf is covered by troughs and ridges lying roughly north-east to south-west

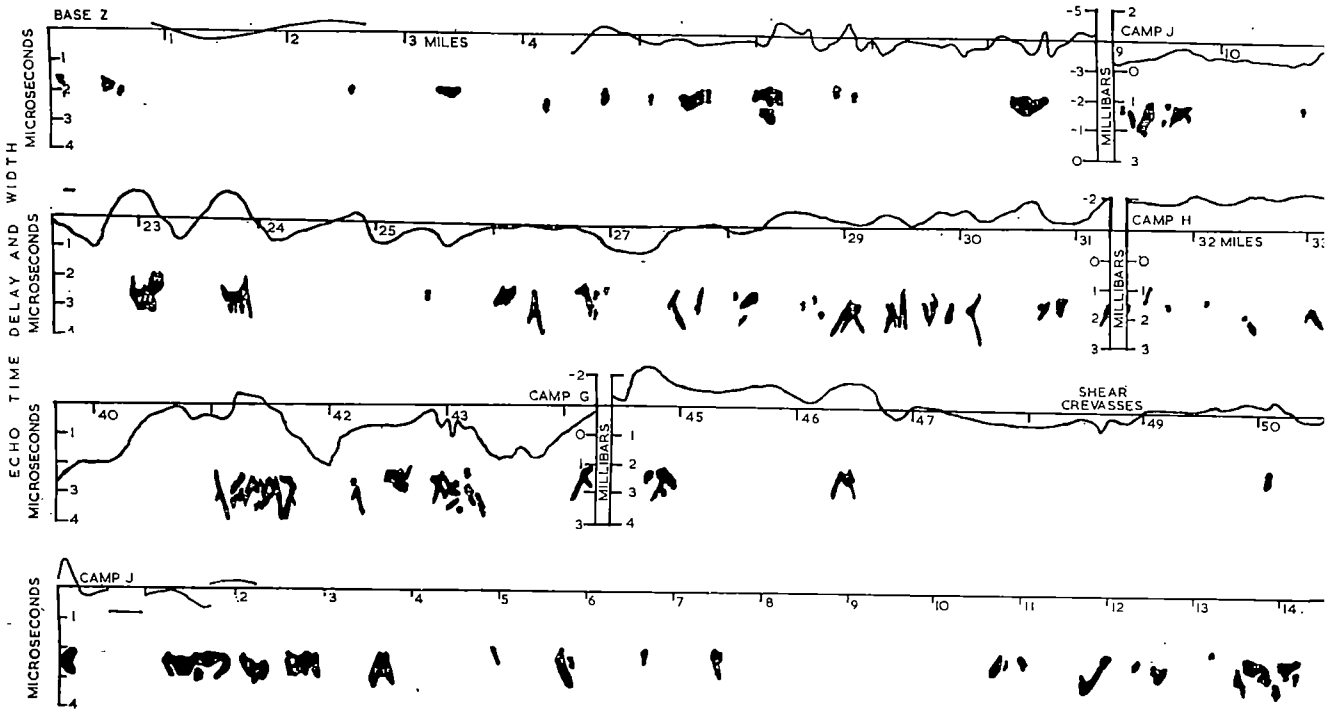

Fig. 3. Barometric pressure and radio echoes plotted against sledge wheel mileages. Pressure, the continuous curve, is plotted in millibars deviation from the daily mean pressure at Base *Z* corrected to mean sea-level. The blocked-in areas represent the time-delay and duration of radio echoes in microseconds. If pressures and time-delays are converted into heights and depths the respective vertical exaggerations are 50 times and 5 times. Note that on the lowest plot (Camp *J* to Flag *AR*617) no barometric pressures are available and that the mileage scale is different from the upper three plots. The inset shows the loci of echoes from discrete targets at various minimum radar ranges from the vehicle track. They are strictly appropriate only to the upper three plots and are calculated assuming 160 m/μsec for the velocity of radio waves in ice

for determining the direction from which an echo is received.

Range information is obtained in the form of a time-interval displayed on a cathode-ray tube as a fraction of the period of a crystal oscillator. The velocity of propagation has been estimated from an experiment in which the transmitting and receiving aerials were separated a distance s apart in a region where the ice depth appeared to be constant. The echo time-delay, t, for the slant path through the ice was measured for a series of spacings and the velocity deduced from the gradient of s^2 against t^2. The method is unfortunately rather sensitive to the slope of the bottom surface of the ice shelf, so a large uncertainty remains in the present result, which is 160 ± 20 m/μsec. Laboratory measurements of the permittivity of natural ice cores (Evans, 1964, in the press) and unpublished field measurements made in Greenland suggest that the most probable velocity is in the upper half of this range and that it depends on the ice density.

The sketch map in Fig. 2 shows that the Brunt Ice Shelf is bounded to the north and east by low shelf, perhaps 50 m thick, while to the south a broken surface slopes down to the junction with the inland ice sheet. Waves of a few metres height (greater in the east) have troughs lying north-east to south-west. Other surface disturbances indicate that there is probably local grounding on the sea bottom.

Depth soundings were made on the route from Camp *J* to flag *AR*617, and from Base *Z* to Camp *F*. The section from Base to Camp *J* was examined about a month earlier. Navigation by compass and sledge wheel proved simple and adequate. The error of closure for the loop of 150 miles was 4 miles which, if significant, is probably due to the difficulty of maintaining a straight track in undulating country. Information was recorded in a notebook using a concise notation to deal with the flow of data. An echo was characterized by its time-delay and code letters designated width, rise time, amplitude, and variation with vehicle movement. In addition, the barometric pressure, sledge wheel mileage and time, were read frequently.

In Fig. 3 the blocked-in areas show the time-delay and duration of radio echoes in microseconds, and the upper curve represents the barometric pressure deviation in millibars from the daily mean pressure at Base *Z* corrected to mean sea-level (Table 2). One millibar is equivalent to about minus 8 m change in altitude in air and 1 μsec is equivalent to 80 ± 10 m depth of ice. Thus, estimated random errors of one-tenth of a millibar and one-tenth of a microsecond in reading the instruments correspond to errors of 0·8 m surface elevation and 8 m depth.

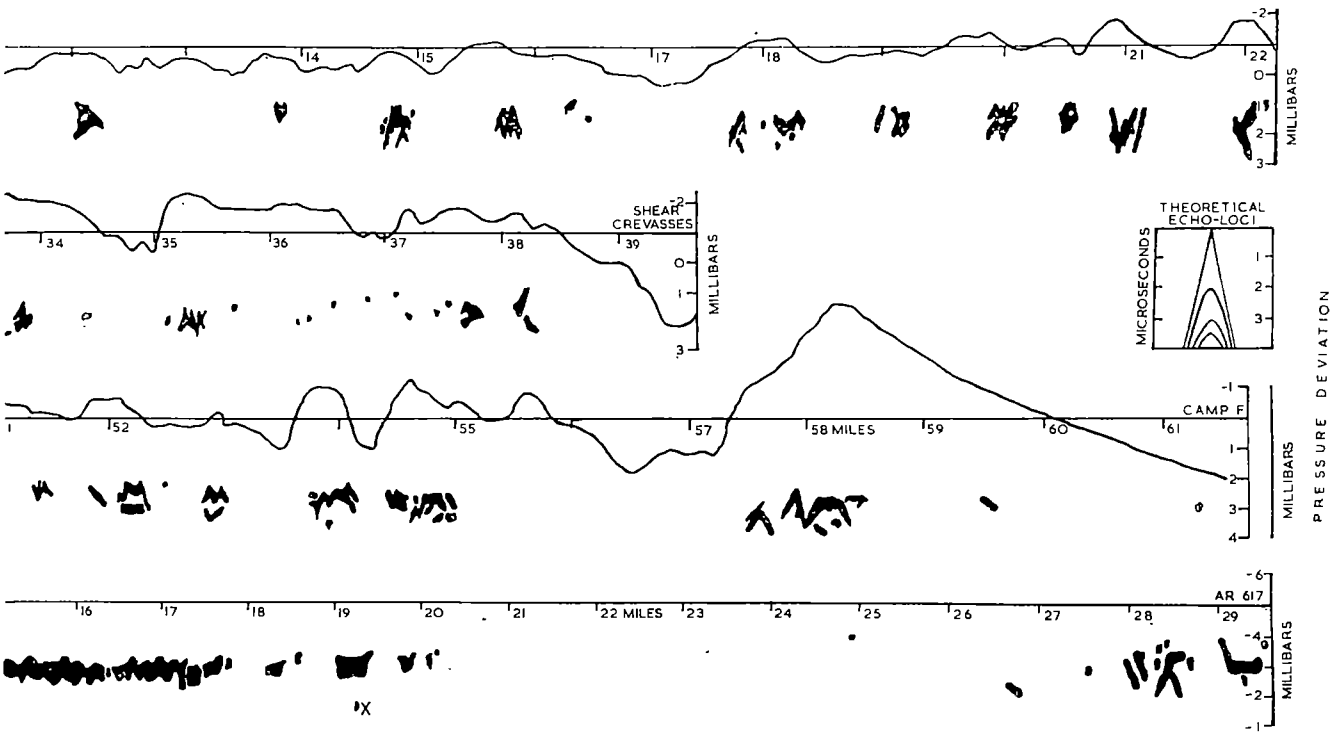

Table 1. Equipment Parameters

Radio frequency band	32–39 Mc/s
Receiver sensitivity	127 db below peak transmitter power
Transmitter pulse width	0·3 μsec
Pulse rise time (10–90 per cent at receiver output)	0·1 μsec
Pulse repetition frequency	10^4/sec
Aerials	Horizontal unipoles

Table 2. Daily Mean Pressures at Base *Z* corrected to Mean Sea-Level

Date, 1963	Journey	Pressure in mbar
Oct. 21	Base *Z* to Camp *J*	975
Dec. 7	Camp *F* to Camp *G*	977
Dec. 8	Camp *G* to Camp *H*	983
Dec. 9	Camp *H* to Camp *J*	989
Dec. 11	Camp *J* to Flag *AR* 617	992

We note first that echoes occur in groups; within groups the echo power averages 30 dB above receiver noise and peak powers of 55 dB are observed in places. Thus we have to explain a huge variation in mean echo strength

from place to place on an almost uniform ice shelf. Secondly, it is clear that the occurrence of the groups is correlated with the barometric readings showing that echoes occur only under the higher portions of the top surface. Finally, within the groups, the locus of an individual echo usually decreases in range to a minimum and then increases again as the vehicle continues along its track. If two distinct echoes converge in range and coalesce the resulting echo amplitude varies with vehicle position in a roughly sinusoidal manner with wave-length 3 to 50 m and fading range of 10 to 20 dB. Otherwise the strength of a single echo changes slowly in a distance less than the shelf thickness.

Echoes at much longer range than the minimum for the group are examined by turning the vehicle and aerials about a vertical axis. The resulting variation in echo strength shows that the targets are at a large angle to the vertical. The only clear exception, marked x in Fig. 3, appears to be due to a pulse which, partially reflected on first reaching the top surface, traverses the ice shelf four times before reception.

Since echoes at range longer than the minimum for the group are found to be oblique, we explain the locus of an individual echo by supposing that it is due to a small, isolated reflecting region which scatters the incident power into a wide solid angle. Theoretical loci for different minimum ranges are shown in the inset to Fig. 3, and can be seen to fit the observed echo shapes adequately. The curvature depends on the velocity of propagation used in the calculation; a target in air would produce a locus extended by a factor 1·8 along the mileage axis. On this explanation the true vertical extent of the ice shelf must be obtained from the minimum time-delay found in a group of many echoes, not from an isolated sounding. Such depths are marked at a number of places in Fig. 2.

Variations in height of the top surface of the ice shelf are often greater than 10 m in amplitude and are separated from one another by distances of about a kilometre; approximately five times the measured ice thickness. If these variations are nearly in hydrostatic equilibrium and the snow density does not increase more rapidly with depth below troughs than below ridges[2], then the thickness of the shelf must vary by about ten times the variation in surface elevation. This is compatible with the hypothesis that ridges occur where the shelf contains icebergs of inland origin, the troughs in between consisting of sea ice and drift snow[3]. If the shelf is not in hydrostatic equilibrium it is difficult to explain how the necessary vertical components of shear stress could arise[4,5].

It is surprising that the radio-echo technique has failed to indicate the ice thickness except below surface ridges. We can only suppose that an absorbing layer at least 10 metres thick at the bottom of the shelf presents no sharp discontinuity in electromagnetic impedance and so reflects no energy. Ragle, Blair and Persson[6] have measured the dielectric loss factor of ice samples taken from the bottom on the Ward Hunt Ice Shelf in the Arctic and found them about 20 times greater than for ice samples taken from near the top surface. The transitional layer could be caused by liquid sea-water permeating into pure ice or by the accumulation of new ice frozen from sea-water. The observed echoes, under ridges, would then arise only where neither process occurs or, following Barclay, where the bottom of the ice shelf consists of inland ice, not sea ice.

This work is part of a programme supported by the British Antarctic Survey. We thank the Committee of the R. W. Paul Instrument Fund for providing a grant to cover the entire cost of developing the radio echo-sounding apparatus.

BIOLOGICAL ASPECTS OF THE POPULATION EXPLOSION*

By Prof. A. S. PARKES, C.B.E., F.R.S.
Physiological Laboratory, University of Cambridge

The Explosion

My first task must be to justify the use of such a word as 'explosion' in connexion with an increase of population, however rapid and unprecedented. This perhaps is not as difficult as might be thought. The explosive growth of world population has taken place over about a century, especially over the past fifty years, during which the number of human beings has doubled. Such an increase in numbers in so small a fraction of human history is indeed remarkable.

It may be that animate beings, recognizable as human, have been in existence on this Earth for 200,000 years. If for the sake of argument we accept this estimate at its face value, it means that it took 199,000 years, that is up to A.D. 1000, for numbers to reach about 300 million. This implies a very slow rate of increase, an average of a mere 1,500 a year, and there is no doubt that during the vastly greater part of human history a high birth-rate was almost neutralized in the ordinary course of events by a high death-rate, and further that from time to time numbers were sharply reduced by epidemics.

By 1650 world population may have been of the order of 500 million. Things had evidently begun to move, but even so the 1,000 million mark was probably not reached until about 1830. Another 1,000 million, to make 2,000 million in all, were added by 1930 and since then more than another 1,000 million have joined the flock. The total in 1962 was thought to be about 3,180 million. In the past 30 years, therefore, as many people have been added to the human race as were to be found after the first 2,000 centuries or so of man's existence. Thirty years in 2,000 centuries corresponds to about 0·5 sec in 1 h, and anything that happens relatively in 0·5 sec to the time-scale of 1 h can reasonably be called an explosion. We are indeed in the early stages of a population explosion of which no one can foresee the end or the full consequences. Any biologist knows what a population growth curve of this kind means; whether the curve relates to bats or bacteria it means that something is going to happen, and in Nature that something is a crash. It remains for the human subject to decide whether in his case that something will be pleasant or unpleasant.

I want now to discuss three matters in connexion with the population explosion.

Cause of the Explosion

First, taking the world as a whole, the enormous increase in population is not due to increased fertility—it has been caused very largely by advances in the medical and related sciences, which have resulted in a comparatively sudden and dramatic fall in the death-rate in areas where the birth-rate remains high. In such circumstances there are more young people than old people to receive the benefits of medical science; as a result the immediate consequence is a tremendous excess of young people. In some parts of the world nearly half the population is less than 14 years of age. In many parts, half is less than 18 years of age. The reproductive potential arising from an age distribution of this kind needs no emphasis. Moreover, the impact of medical science on world population is accelerating.

The tempo of this increase in the expectation of life will no doubt slacken, but evidently, taking the world as a whole, it has a long way to go before everyone dies essentially of senescence; and what about senescence? In spite of the very large increase in the expectation of life at birth, the expectation of life at 65 or 70 years of age has increased comparatively little (though, of course, many more people live to expect it). In other words, medical science, fully engaged in the conquest of disease, has done little towards defeating senescence. It is a moot point whether or not medical science should add this problem to its programme. Whatever the demographic effects might be, and there seems to be some doubt about this, the social effects would be disturbing, to say the least, if a large majority, instead of a tiny minority, of people lived to be 100 years old.

Differential Rates of Increase

The second point to which I wish to direct attention is that the increase in population is very different in different parts of the world.

There is thus a continuous shift in the balance of world population, and figures of this kind hold a very pointed lesson for Great Britain. So long as present trends continue the inhabitants of these islands will constitute a progressively smaller proportion of the human race. How then are we going to hold even our present somewhat attenuated position in the world? Evidently, if we cannot rely on quantity we must rely on quality, and for this reason, if no other, serious consideration of the genetic improvement of the race, if only by negative means, should not be delayed indefinitely. In the meantime, most people would agree that we should try to make the most of everyone we have, and that presumably means education and more education and training and more training. But education and training in what? Great Britain is reaching a position in a competitive, populous and technological world where it can ill afford to fritter away its talent. We hear much about the brain drain to the United States. Is it not time we heard more about the brain drain into unproductive forms of scholarship? In asking this I do not wish to imply that all forms of science are obviously productive. In fact there is no clear distinction between 'pure' and applied science: either may, and often does, merge into and stimulate the other.

Nature's Limiting Factors

My third point about the population explosion is that it provides a good illustration of a very important biological principle. In Nature the first job of a species is to survive, and to this end reproductive capacity is such that any living thing able to multiply without hindrance to the limit of its reproductive capacity would soon swamp the world. The fact that this does not happen shows very clearly that all populations are held in check by limiting factors, of which the main ones are food supply, disease and enemies. This applies even to the slow-breeding mammal and to man himself. In human terms these limiting factors are famine, pestilence and war—the traditional scourges of mankind. In Nature, the relaxation of one limiting factor allows a population to increase until it bumps up against the same factor again, perhaps in a modified form, or against one of the other two. In the case of man, medical science has greatly relaxed the limiting factor in infective disease, and under natural conditions the present population explosion would be halted by the reappearance of control by disease, using

* Substance of an Evening Discourse delivered before the British Association (Southampton) on August 31.

the word in its widest sense, by famine or by war. It remains for man to break the grip of these harsh limiting factors of Nature. How is this to be done?

Explosive Power of Geometric Progression

It has often been said that it should be possible to increase food supplies and other resources as fast as the population increases. This, however, would not be enough. At the present time it is admitted that one-quarter of the world's population is malnourished and another quarter undernourished. If the general standard of living throughout the world is to be raised to an acceptable level it will be necessary for resources to increase faster than population, and at present this is certainly not happening adequately. No doubt resources will be increased very largely, but there is no possibility of the increase being commensurate with the reproductive potential of the human race. It is deplorably easy to overlook the force of geometric progression. The present rate of increase of the world population is about 2 per cent per annum, and here I want to quote from the report published last year by the U.S. National Academy of Sciences on the *Growth of World Population*.

"Although the current 2% per year does not sound like an extraordinary rate of increase a few simple calculations demonstrate that such a rate of increase in human population could not possibly continue for more than a few hundred years. Had this rate existed from the time of Christ to now the world population would have increased in this period by a factor of about 7×10^{16}. In other words there would be about 20 million individuals in place of each person now alive or 100 people to each square foot."

The Academy report goes on to extrapolate into the future:

"If the present world population should continue to increase at its present rate of 2% per annum then within two centuries there will be more than 150 billion* people."

That is fifty times as many people as we have to-day, to be fed, housed, educated, exercised, transported and given the amenities of life, and all this in a habitat which in many places is already being destroyed by man's activities. The American report concludes:

"Calculations of this sort demonstrate without question not only that the current continued increase in the rate of population growth must cease, but also that this rate must decline again. There can be no doubt concerning this long-term prognosis. *Either the birth-rate of the world must come down or the death-rate must go back up.*"

This quotation shows the futility of arguments based on the indefinite increase of resources. Even if technically possible to produce, adequate resources would be little consolation to people for whom there was not even standing room.

Pathological Togetherness

Nor, it seems, would adequate resources stave off the biological effects of overcrowding. I have already said that I was using the word 'disease' in its widest sense: and here I want to quote from a recent paper by Hudson Hoagland on "The Cybernetics of Population Control". In speaking about the rabbits of Minnesota, Hoagland says:

"These populations rise and fall through cycles of several years' duration. There is a build-up followed by a dying off. Why do these marked oscillations in numbers of rabbits occur? It was observed that when the animals died off there was usually plenty of food—they didn't starve. There were no evidences of an excessive number of predators. Furthermore, the bodies showed no sign of any specific epidemic that killed them."

* 'Billion' in the United States and elsewhere equals a thousand millions; in Great Britain and elsewhere it equals a million millions.

Hoagland cites many examples of the rise and fall of natural populations where the fall could not be attributed to lack of food, enemies or infective disease. He also refers to experiments by Calhoun in which rats kept at merely double the density compatible with a healthy population showed low fertility associated with a great variety of physiological and behavioural abnormalities.

Here then is a new aspect of population control by disease—the pathology of overpopulation, of which the symptoms are highly suggestive of the stress syndrome characterized by hyperactivity of the pituitary–adrenal axis.

For those who dislike the expression pathology of overpopulation, I would recommend that coined by Calhoun, 'pathological togetherness'.

The 'Demographic Cycle'

I should emphasize that the idea of the crash of populations caused by overcrowding must be clearly distinguished from the idea of the so-called demographic cycle in man, which postulates that with an increased standard of living the birth-rate falls naturally without conscious fertility control and will do so in the East as it has already done in the West. This idea seems to have little biological foundation, because: (*a*) according to present indications a fall in the birth-rate in the East will have to precede, not follow, an increase in the standard of living; (*b*) in the absence of any conclusive evidence of a decline in the biological fertility of the people concerned, the fall in the birth-rate in the West has presumably been caused by the conscious control of fertility by some means or other; (*c*) present evidence is that the demographic cycle can go into reverse, and that with a very high standard of living, the birth-rate tends to rise again, as it has done in the United States and to a lesser extent in Great Britain since the Second World War.

The Human Limiting Factor

The indefinite increase of resources, therefore, even if it could be achieved, might lead only to pathological togetherness, and the idea of a natural demographic cycle is largely illusory. Some more positive human limiting factor is evidently required if we are to avoid the harsh limiting factors of Nature. This fourth, human and humane factor, can only be the possession of the will and the means for the conscious control of human fertility. Stated simple and bluntly, the fact is that medical science has put the human race in a position where man's urge to mate can be reconciled with the bearing capacity of our planet only by conscious limitation of the results of mating. Surely few would wish to achieve this aim by means other than the control of conception.

This raises the important question of what constitutes conception in man—the fertilization of the egg or its implantation in the uterus some days later. My own view is that implantation, not fertilization, constitutes conception, and I base this view on the biological analogy that no one maintains that a hen conceives when her egg is fertilized or that she aborts when she lays it. On this view contraception can properly be exercised up to the time of implantation. Whatever the precise definition, if the idea of contraception is to be accepted for both population control and family planning, then surely methods should be as effective, simple and acceptable as possible. Yet up to recently, available methods of contraception were archaic in principle and a disgrace to science in an age of spectacular technical progress. This unhappy situation arose from the taboo which for long surrounded the subject and which not only drove it underground but also inhibited scientific work in the field.

Fortunately, the situation has now changed, and for this we owe much to the biological breakthrough, pioneered by Pincus and Rock, which has resulted in the

development of oral contraception for the female by means of 'the pill'. It is not my purpose to discuss the biological background or the very high effectiveness of this remarkable form of medication. Both are most interesting and important, but it may be that in years to come the Pincus–Rock pill will be thought of as having made its main contribution in the psycho-social field. I say this because the pill, by reason of having dissociated fertility control from the act of coitus, has promoted discussion of the matter in a remarkable way.

The advent of the pill—that dream of family planners—has naturally raised serious questions about the possible long-term effects of such medication. Here again, this is no place to discuss technical pros and cons, but I would make some comments of a general nature. The first is that the possible hazards of using contraception must be balanced against the possible or even certain hazards of not doing so—apprehension, oppressive pregnancies, abortion, unwanted children, overpopulation. The second is that the pill is the most effective and acceptable form of fertility control so far available. The third is that the intensive research now in progress will almost certainly produce equally or even more effective and acceptable methods in the not-distant future, so that alternation of methods will make it possible to avoid possible hazards arising from the long-term use of any particular one.

Size of Family and Population Growth

There is now available, therefore, at least one very efficient biological method of preventing conception. Undoubtedly other and better ones will follow. We shall thus have the means to control the growth of population. Will this solve the problem?

Obviously the first requirement is the spread of information and the avoidance of unwanted children: we must hope that this will be only a matter of time. The real long-term question is motivation. Will people want to limit their families to a level which, in the light of present medical trends, is compatible with no more than an acceptable rate of population increase? We have seen that an annual increase of 2 per cent cannot be maintained, and it is arguable that the population should be stabilized at its present level so that increase of resources can be used to increase the standard of living in parts of the world where it is low, rather than to provide for more people. There are, however, disadvantages in a static population and probably some slight increase, possibly 0·5 per cent per annum, would be acceptable. This raises the very interesting question of what average size of family an increase of this small amount would represent. Allowing for mortality rates as found in the West and for a generation interval of 25 years, the answer seems to be something less than 2·5 (Table 1).

Table 1

Average size of completed family per married couple	Rate of growth of population (% p.a.)
2	—
2¼	3/4
3	1¼
3½	2¼
4	3

Motivation towards small families, that is families of 2 or 3, for either personal or demographic reasons, is going to be very difficult in areas of traditionally high birth-rate. This is especially true where a large family is a status symbol or a source of cheap labour. In the East, therefore, the chance of getting the average size of family down to 2¼ in the near future is anything but good. What about the West? Large families of the size often seen in Victorian times are now rare; but they are not unheard of even among educated and knowledgeable people. This raises in acute form the question posed by A. V. Hill in his presidential address to the British Association in 1952, the question of whether the rights of man, about which much is heard, can under modern conditions be held to include the right to unlimited reproduction. It would seem that now or in the visible future the answer must be: no. Even a family size of four would be catastrophic if it became general.

Here then is an acute social problem of motivation. Evolution has endowed man not only with an urge to mate, but also with a parental urge at a level appropriate to a low survival rate. Medical science has altered one, but not the other. Our present dilemma is indeed a striking example of the effects of unilaterally interfering with Nature. What must be done to redress the balance? We cannot put back the clock of medical progress and we cannot cope on the planet Earth with unlimited numbers of people. Emigration to other planets is not likely to be a practical solution within the visible future. Mass reduction of fertility, as, for example, by the medication of a staple food, would be possible only under a rigid dictatorship. Possibly economic pressures and inducements will have to be used. Certainly, by some means, the parental urge will have to be further diverted from quantity to quality, with all that quality implies. I do not pretend to know the answers; but as a biologist I would like to conclude with this thought—that the development of both the means and the will to match his fertility to his environment and so to avoid the harsh limiting factors of Nature will be a fundamentally significant stage in the continued evolution of the human race.

A NEW THEORY TO EXPLAIN CROSSING-OVER BETWEEN GENES ON CHROMOSOMES

By Prof. CARL C. LINDEGREN
Biological Research Laboratory, Southern Illinois University, Carbondale

Belling's Theory, 1931

Belling's[1] cytological investigation of synapsis and chiasmata in liliaceous plants with large chromomeres led to his proposal in 1931 of a theory of crossing-over based on his direct cytological observations. He stated that the 'new' chromatids, formed after synapsis, were produced: (1) by the duplication of the 'old' chromioles to produce 'new' chromioles; (2) by the outgrowth, extension and union of interchromiolar (non-genic) filaments on the 'new' chromioles. He inferred that crossing-over occurred by cross union of the two 'new' strands formed after synapsis. Belling proposed that when a twist occurred in the two 'old' synapsed strands, followed by duplication of the 'old' chromioles to produce 'new' chromioles, a cross union, producing a 'cross-over', might occur at the point of the twist between two of the 'new' non-sister strands (Fig. 1). The two 'old' strands would remain 'non-crossed-over'. Belling's 1931 theory proposed that crossing-over never occurred between the two 'old' strands but only between the two 'new' strands. Therefore, each tetrad of chromatids always produced two

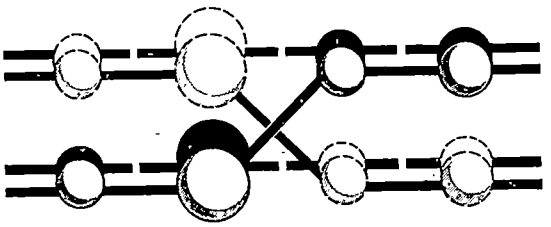

Fig. 1

'non-crossed-over', 'original', 'old' strands along the entire length of the chromosome; the cross-overs (or crossed-over strands) of the tetrad would involve only the two 'new' strands. Belling rejected the concept of breakage of any of the strands; crossing-over, according to him, was only due to the cross union of the newly formed 'interchromiolar' connexions.

I shall propose: (1) that the interchromiolar connexions are probably histone rather than DNA; (2) that the DNA in the chromosome is discontinuous; (3) that the gene is a particulate structure containing DNA. The kind of crossing-over discussed herein occurs between and not within genes and probably involves histones rather than DNA; the new theory does not concern the kind of genetic recombination which occurs in viruses nor between the DNA components of chromosomes.

Contradiction of Belling's 1931 Theory

Belling's 1931 theory was rejected by Beadle and Emerson[2], who argued that the *Drosophila* data proved it to be incorrect. Their analysis of chromatid interference in *Drosophila* contradicted Belling's early theory, because, according to Belling, only the two 'new' strands would be involved in exchanges. Bridges[3] was the first to demonstrate by genetical analysis that crossing-over occurred at the four-strand stage. Beadle and Emerson, using attached-*X* flies prepared by Bridges, demonstrated genetically that multiple exchanges could involve more than only the two 'new' strands; three or four strands were involved with high frequencies in multiple exchanges. The involvement of more than two strands proved that the 'old' strands also could be involved in crossing-over. Beadle and Emerson named the three different kinds of multiple exchanges '2-strand', '3-strand' and '4-strand' multiple exchanges. Multiple exchanges were usually studied over two adjacent regions and designated as 'double' exchanges. The ratios of the three different kinds of possible double exchanges were the basic data of the analysis. Beadle and Emerson concluded that the ratio of 2- : 3- : 4-strand 'doubles' in *Drosophila* was 1 : 2 : 1. Their results did, indeed, suggest that 'double' exchanges occur at random, but this was probably because the genes which they studied were too far apart to escape ambiguities due to undetected multiple exchanges which 'randomized' the ratios. Bonnier and Nordenskiold[4], using the same material, failed to confirm their findings. Beadle and Emerson's conclusions were contradicted by Lindegren[5], who showed that in *Neurospora* the relative frequencies of the three kinds of doubles was 2- > 3- > 4-strand double exchanges. These frequencies have been corroborated in recent unpublished analyses of heterozygous yeast hybrids marked for 10 different regions in one chromosome.

Belling's Revised 1933 Theory

Belling[6], after the criticism of Beadle and Emerson, revised his theory to fit what he considered to be the facts on the basis of their *Drosophila* data. In his revised theory, Belling proposed that the chromioles were indeterminate with regard to 'newness' or 'oldness' and that this indeterminancy could produce sister-strand crossing-over. But he continued to reject breakage as a possible cause of crossing-over.

Cleavage Planes of the Chromioles

In Belling's revision of his theory he assumed that the axis of cleavage of the chromioles was at random, leading to a high frequency of what would be equivalent to sister-strand crossing-over. But the axis of cleavage of the chromioles is probably predetermined and parallel to the long axis of the chromosome. In the analysis of heterozygous attached-*X* females, Bridges found only occasional females homozygous for recessive genes, proving that crossing-over had occurred when the 4-strands were present. But most of the daughters of attached-*X* females are heterozygous. The high frequency of heterozygous daughters compels acceptance of the view that the line of cleavage of the two attached-*X* centromeres in the mother must be predetermined to pass through the dotted line shown in Fig. 2. If cleavage occurred in other planes, recessives, trisomics and other irregular kinds of daughters would occur with high frequency. These considerations prove: (1) that the attachment of the centromeres in attached-*X*'s must occur at specific and corresponding points on the surface of the two respective centromeres; (2) that the insertions of the interchromiolar connexions into the centromeres must be precisely located; (3) that the cleavage plane must pass through both the attached centromeres between the insertions of the interchromiolar connexions; (4) through the points of attachment; (5) at right angles to the attachment points. Extension of these considerations to the cleavage of the 'old' chromioles suggests: (6) that the cleavage planes of chromioles are likewise orderly and predetermined; (7) that the 'old' and 'new' chromioles are distinguishable from each other.

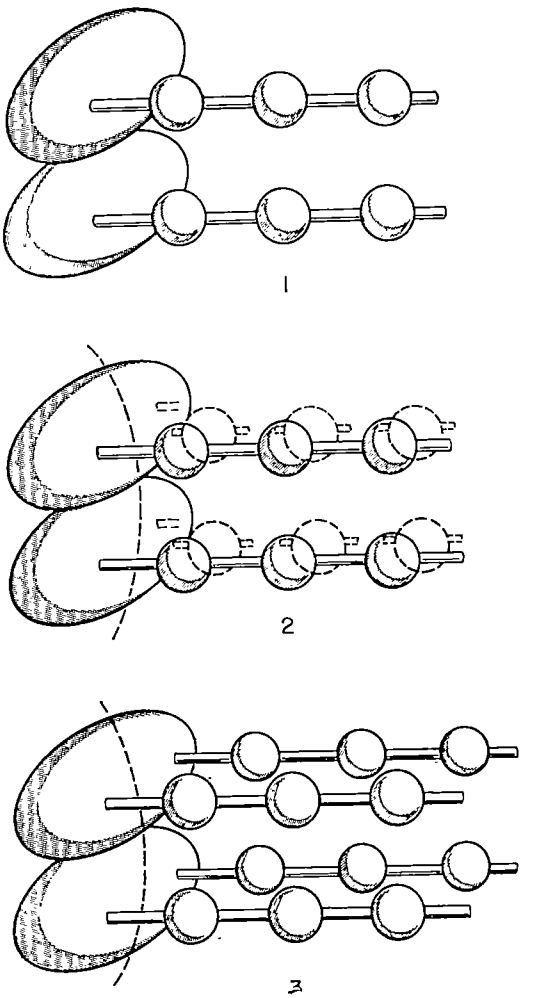

Fig. 2

Darlington's Theory

Darlington's[7] theory, like Belling's, proposed: (1) that crossing-over occurred at the 4-strand stage before the chiasmata appeared; (2) that the chiasma was produced by opening up the synapsed strands after the cross-over had occurred. Darlington disagreed completely with Belling on the cause of crossing-over, because Darlington contended that all cross-overs were due to breakage and reunion. He asserted that twisting of the chromosomes caused breakages at the 4-strand stage which then led to cross reunions. I have tested many different kinds of strands by twisting four strands together until breakage occurred; under these circumstances the strain of twisting is always relieved at first by the breakage of only one strand, never by the breakage of two or more strands. For this reason, I have always been more inclined toward Belling's theory.

The New Theory

Neither Belling's nor Darlington's theory explains the observed frequencies of double exchanges. The analysis of yeast hybrids has proved beyond question that in yeast, as in *Neurospora*, the frequency of 2-strand doubles exceeds the frequency of 3-strand doubles and that 4-strand doubles are the least frequent of the three categories. I shall propose a new explanation of crossing-over consistent with this distribution. This theory proposes: (1) that the primary cause of crossing-over is a twist in the synapsed strands with cross unions between non-homologues, as proposed by Belling in 1931; (2) that some twists may lead to the breakage of one of the two twisted strands before the 4-strand stage; (3) that duplication of the chromioles after such a break will produce three pairs of free 'interchromiolar' connexions; (4) that in such circumstances a union of a 'new' and an 'old' strand is possible; (5) that, since there will be six free 'interchromiolar' connexions after the chromioles have divided and have produced their outgrowths, the three pairs of free ends may either grow together to produce no new relationships or the strands may reunite to produce cross-overs. The theory holds that breakage of one strand, occurring at a twist point before the chromosome has become quadripartite, is the event which makes union of an 'old' and a 'new' strand (as well as sister-strand crossing-over) possible. If breakage at the twist points is relatively rare, the frequency of 2-strand double exchanges would greatly exceed the frequency of 3-strand doubles, as has been demonstrated in both *Neurospora* and yeasts. If breaks occurred at two adjacent twist points, an occasional 4-strand double could occur.

This explanation is consistent with the observed frequencies of the three different kinds of double exchanges. If twists and breaks occur with high frequency the distribution of double exchanges might be random—1 : 2 : 1. (Belling's revision predicted a 1 : 2 : 1 frequency distribution of 2- : 3-: 4-strand doubles.) The new theory proposes: (1) that all cross-overs occur at the 4-strand stage by cross union between chromioles of the interchromiolar histone filaments; (2) that most cross-overs are due to twists in the synapsed strands with cross unions occurring according to Belling's 1931 hypothesis to produce cross-overs only between the two 'new' strands; (3) that, occasionally, twists are so tight that one of the two 'old' strands at the twist point breaks leaving six free ends; (4) that in this circumstance a cross union may occur between two 'new' strands or between an 'old' and a 'new' strand, or may not produce a detectable cross-over, depending on how the unions occur; (5) that, if a non-sister cross-over between an old and new strand occurs, then a Belling-type cross-over at an adjacent twist could produce a 3-strand double (if a sister-strand cross-over occurred between two Belling-type exchanges, a 3-strand double could also occur); (6) that, if a detectable cross-over has occurred at the first twist due to the breakage of a single strand, and if, at an adjacent twist, a different strand breaks, a 4-strand double might be produced.

This work was supported by a research grant from the American Cancer Society.

ALARM SUBSTANCES AND ALARM BEHAVIOUR IN SOCIAL HYMENOPTERA

By Dr. ULRICH W. MASCHWITZ
Institut für angewandte Zoologie, Universität, Würzburg

HIGHLY developed social communities of Hymenoptera make use of alarm communication. An alarm can be given by optical, mechanical or chemical means. The possibility of chemical alarm communication has been known for a long time. Huber[1] found in *Apis mellifera* that the sting odour is an attack releaser, while Staeger[2], Weyrauch[3] and Goetsch[4] supposed alarm could be released by optical or mechanical means. The last-named, however, also indicated alarm substances. The problem has recently been examined by several investigators. In all communities of Hymenoptera examined chemical alarm communication could be demonstrated; this was shown in the honey-bee by Free[5], Lecomte[6], Ghent *et al.*[7] and Boch *et al.*[8] and in some ants by Wilson[9,10], Sudd[11], Brown[12] and Hunt[13]. Some alarm substances have already been identified, such as citral in *Atta sexdens*[14], different ketones in *Tapinoma nigerrimum*[15] and *Iridomyrmex pruinosus*[16] and isoamylacetate in the honey-bee[8].

These fragmentary and somewhat contradictory results led to a comparative investigation of alarm and alarm substances[17].

In the honey-bee colony an alarm can be demonstrated best when only single bees are sitting in front of the entrance to the hive, as they do at dawn or on a cool day. Then, when some bees are excited by pressing, they run into the interior of the hive and after a short time a great number of workers come out of the hive, run about excitedly, and are ready to sting. The same behaviour can be simulated when a squashed sting is put at the hive entrance. The workers come out of the hive interior, approach the sting, and smell it. Then they run excitedly about on the hive board, ready to attack. The attraction effect has been used by many investigators[7,8,17] as a test reaction. Excited bees without a sting are not able to alarm other workers. This shows that only chemical stimulants can release an alarm. The excited worker bee exhibits a characteristic behaviour (Fig. 1) which resembles the fanning reaction. The bee erects its abdomen, opens the sting chamber and its sting is extruded. Sometimes a droplet appears on the tip of the sting. In this posture the bee runs buzzing among the others, which are excited and ready to attack. If more bees are excited the pleasant odour of the alarm substance

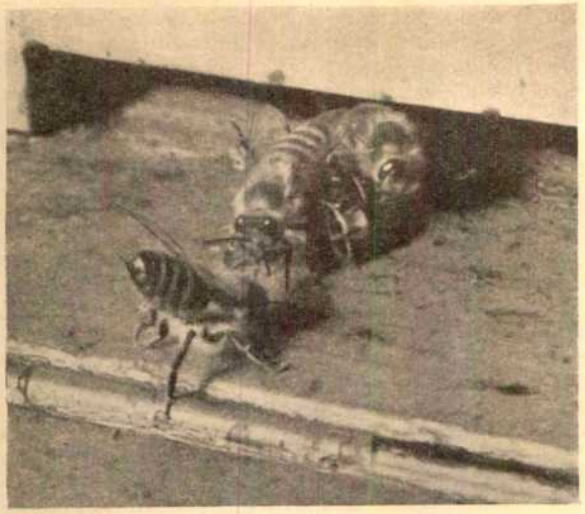

Fig. 1. An alarmed honey-bee which has been excited by pressing. In the opened sting chamber the sting and a bristled membrane can be seen. In the latter the alarm substance is exposed stored

can be recognized, which is released by the alarm fanning. The alarm secretion is exuded in the region between the bristles of a setose membrane which connects the oblong plates of the sting apparatus. It can evaporate when the sting is protruded into the open air.

At present we do not know in which gland the substance is produced (Fig. 2). Four different glands are situated in the sting of the honey-bee[18]. Only one of them, the big poison gland, runs directly into the sting shaft. The three other glands open into the sting chamber; the alcaline or Dufour gland, the paired Koshewnikov gland lying on the quadrate plates, and the newly discovered paired sting sheath gland. Ghent and Gary[7] supposed that the origin of the alarm substance is the Koshewnikov gland. But the bees showed no reaction to a large number of fresh glands simultaneously squashed. Experiments with poison glands, alcaline glands, and sting sheath glands produced the same result. The sting sheath gland can be eliminated in a second way. Freshly emerged bees have no alarm substance. The sting sheaths were removed from such bees. Nevertheless, after a week when the alarm secretion normally was fully developed, these bees also had a scented, alarm-releasing sting.

Comparison with the queen honey-bee is also not significant. Although the female has no alarm substance in her sting apparatus the same glands can be found. They are the same size or are even larger than the glands in the worker bee.

In the worker honey-bee another weak alarm substance has been found—the contents of the mandibular gland. Boch[19] also discovered that it attracts other bees. Its smell is quite different from that of the sting odour.

The alarm substance is of great importance not only for alerting the workers but also for a subsequent attack by the bees. It lowers the threshold of sensitivity for the attack reaction and enables the bees to locate the spot which has already been stung. This spot, however, has to be optically attractive at the same time, that is, it has to be dark or it has to be moving[7,17].

Alarm substances have also been demonstrated in the wasps *Vespa germanica* and *Vespa vulgaris*. If a wasp is seized or pressed in the nest entrance it gives the alarm and a number of workers rush out from the interior of the nest. They fly off and attack objects in the surrounding area. The same effect can be obtained with a squashed sting. The alarm substance, with an odour resembling fermenting fruit, is in the venom. It is an easily evaporating ether-soluble substance which is mixed with the venomous substances[20].

The alarm reaction corresponds to the wasp's morphological characteristics. The excited wasp turns the tip of its abdomen into the direction of the disturbance and sprays a few jets of venom for several centimetres. Like the honey-bee, the wasp alarm secretions act specifically. A number of other substances were tested (plant and animal odours, chemicals and repellents). The typical alarm could only be released by the alarm substance itself. In *Vespa*, however, an interspecific effect of the alarm secretions has been demonstrated: in *Vespa vulgaris* the venom of *V. germanica* released an alarm and vice versa. Whether the alarm substances are identical, only chemical analysis can prove. The close relationship of the wasps and the same odour for the human nose make this probable. *Polistes* venom and *Apis* alarm secretion are not effective. In the same way as in the honey-bee, the stings of *Bombus* and *Vespa* release no alarm. Wasp queens, too, possess alarm substances which are sprayed off in the same way as in worker wasps, when being pressed. The queens, however, do not join in attack. In wasps the alarm substance has the same importance for attack as in the honey-bee. Here, too, scent-marked subjects were more often and more intensely attacked than were odourless wasps.

Ants, with their bad sight, communicate principally by chemical means. Odour trails laid by the foragers lead the workers to the feeding places[21,22]. Nest mates, offspring, and dead ants are recognized by a specific odour and treated accordingly[4,23–25]. Alarm, too, is mostly given chemically. Most of the myrmicines possess mandibular gland substances[4] (*Pogonomyrmex*[9], *Solenopsis*[24], and *Atta*[14]). The heads of four species of *Myrmica*, *Tetramorium caespitum*, *Pheidole pallidula*, *Messor in-*

stabilis, *M. barbarus*, *Cremastogaster scutellaris*, *C. auberti* and *Aphaenogaster testacea-pilosa* release an alarm reaction. The alarm substance originates, so far as we know, from the mandibular gland (*Myrmica*, *Tetramorium*). At the same time *Tetramorium*, *Myrmica*, *Messor*, and *Pheidole* possess abdominal alarm substances, which are produced, so far as we know, in the poison gland (*Myrmica*, *Tetramorium*). In field experiments, *Aphaenogaster* and *Cremastogaster* showed no reaction to gasters of squashed nest mates near the trail or at the feeding place. In the first four genera alarm is therefore doubly secured. Perhaps the abdominal substances were used for trail marking, also. Venom, as well as the mandibular substance, is given off in situations of danger. When *Myrmica* is biting other ants or when it is pinched one can smell the characteristic ketone-like scent of the mandibular substance. When the ant is seized with tweezers one can observe that the venom, too, emerges from the extruded sting without the ant having stung.

A multiple securing of the alarm can also be found in *Formica* (*Formica polyctena*, *F. cinerea* and *F. fusca*). Mandibular gland secretions, as well as Dufour gland and venom gland contents, alarm the workers of *Formica*. The last two substances are released together. This could be demonstrated by neutralizing the formic acid of the secretion. *Lasius* (*L. niger*, *fuliginosus*, *flavus* and *brunneus*) and *Plagiolepis pygmaea*, too, release Dufour gland secretion together with formic acid. In these two genera, however, only the former substance causes alarm.

Therefore, the typical acid-spraying behaviour of *Formica* is not only a defence reaction but also an alarm behaviour. *Serviformica* and *Lasius* only release a droplet of the alarming venom when disturbed. In doing so *Lasius niger* and *flavus* often erect the gaster like the honey-bee and run between the nest mates, which become excited in this way.

The sting apparatus of the dolichoderines is reduced. For their defence these ants use anal gland secretions, which in *Tapinoma nigerrimum* and *Iridomyrmex pruinosus* mainly consist of strong-smelling, poisonous ketones[15,16]. These ketones function as venoms as well as alarm substances[15,10,16]. We found an alarm function for the anal glands in *Tapinoma erraticum* and *Bothriomyrmex meridionalis*. The alarm substance was released in droplets when pressure was exerted on the ants.

So far, only the location of alarm production and the method of its release have been reported. The behaviour of the alarmed ants will now be described.

An attack can be met in two ways. The workers either fly away or counter-attack. Both reactions occur among ants. In the nest, where brood and queen have to be defended, ants attack their enemies. They approach the alarm spot, circle around it with partly opened mandibles and smell it (Fig. 3). Some of them bite the smelling object and try to pull it about. At the feeding place, the defence of which is not important, different reactions can be observed. Some ants show typical flight reactions (*Tapinoma erraticum*, *Aphaenogaster testacea-pilosa* and *Lasius niger*). The honey-water feeding ants become restless after some time when they have smelt the alarm substance and fly into their nest. Newcomers will return. Between attack and flight reactions transitions can be found. In good fighting ants, for example, *Formica polyctena* or *Tapinoma erraticum* ssp. *nigerrima*, alarm can serve for recruiting other ants in order to overwhelm a strong prey.

As in wasps, species-specificity has also been investigated in ants. Wilson and Pavan[10] have shown that the alarm-

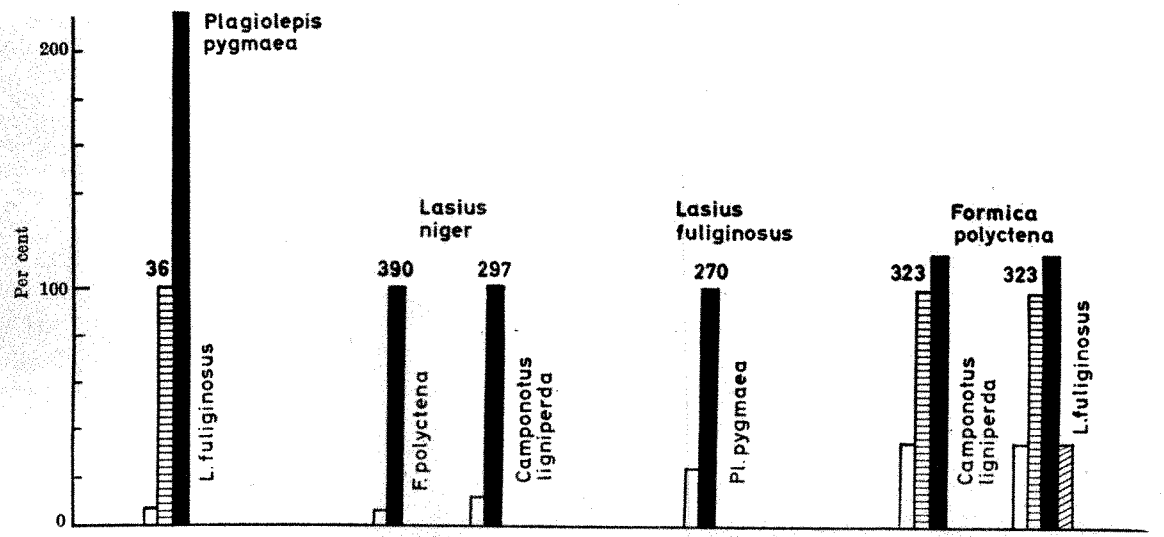

Fig. 4. Specificity of alarm substances within the sub-family of camponotines. Test with Dufour gland secretion. Left column (white), control test without odorous substances; right column (black), number of ants which reacted to the alarm substance of a strange species (percentage of workers which reacted to the alarm substance of their own species (horizontally hatched column)). Absolute values of the median columns (100 per cent) are approximate. Obliquely hatched, mandibular substance of *Lasius fuliginosus*

releasing ketones of *Tapinoma*, *Liometopym* and *Monacis* act intergenerically.

In some genera species-specificity was examined. In *Myrmica* it has been shown that the venom of *M. laevinodis*, *sulcinodis* and *rubida* stimulates alarm in *M. ruginodis*, and vice versa. The mandibular gland substances, too, are not species-specific in *ruginodis*, *sulcinodis* and *laevinodis*. Mandible gland substance from *M. rubinda*, however, is not so effective as the secretions of the other species, although its gland is much bigger than that of *M. ruginodis*. This is understood because it belongs to a different sub-species (*Neomyrma*) from the three others. For the human nose its odour is also different from that of the three others. The mandibular gland substances and the Dufour gland substances of the three species of *Formica* (*polyctena*, *cinerea*, *fusca*) are reciprocally effective, likewise the Dufour gland substances of four species of *Lasius* (*niger*, *fuliginosus*, *brunneus* and *flavus*). For the human nose the Dufour gland substances of *Lasius*, *Formica* and *Plagiolepis* have the same odour, therefore their intergenerical effectiveness was investigated. The results were positive (Fig. 4).

For *Myrmica ruginodis*, however, with the exception of the abdominal substance of *Pheidole pallidula*, the alarm substances of other myrmicines, such as *Messor*, *Tetramorium*, *Leptothorax*, are ineffective.

In summary, it may be said that the alarm substances of the social Hymenoptera are always connected with organs and glands of defence (with the mandibles, the sting, or anal glands). They originate either separated from the venom and are mixed with it when released (honey-bee and Camponotinae) or they originate directly from the venom gland. In the latter case they can be identical with the venom (formic acid in *Formica*, ketones in Dolichoderinae) or not (*Vespa*, Myrmicinae). The specifically acting substances are released when the workers are excited. The alarmed insects usually attack but sometimes they fly away. The alarm substances are not species-specific as a rule; in Camponotinae, even intergenerically acting substances were found.

So far only highly organized Hymenoptera colonies with great numbers of workers have been treated. They all possess alarm substances. Some Hymenoptera colonies, however, have been found which cannot give a chemical alarm. In bees three species of bumble bees were found (*Bombus lucorum*, *hortorum* and *hypnorum*), in wasps *Polistes dubia*, and in ants *Ponera coarctata* (Ponerinae) and *Myrmecina graminicola* (Myrmicinae). All these colonies are very small and have only a few workers, usually less than 100. A disturbance can be directly noted by all nest inhabitants. Therefore development of a chemical alarm system seems to be biologically unnecessary for them.

I thank Springer-Verlag (Heidelberg) for permission to reproduce the illustrations, which appeared first in *Zeitschrift für vergleichende Physiologie*, **47**, 596 (1964).

OBITUARIES

Dr. L. E. Bayliss

LEONARD BAYLISS, who died on August 20 in his sixty-fourth year, was widely known for three achievements: his work on the rheology of blood, his notable two-volume *Principles of General Physiology* in 1959 and 1960 and, particularly to medical students, as co-author of *Human Physiology* in five editions (1930–62).

Blood rheology investigations began about 1930 after he had spent a year in Philadelphia with A. N. Richards collecting glomerular fluid from frogs' kidneys with micropipettes and comparing its oncotic pressure with that of the plasma. Earlier, he had worked with his uncle, E. H. Starling, professor of physiology in University College London, on heart–lung–kidney preparations of dogs, investigating oxygenation and *p*H of the blood and metabolism of the preparation. About then, Fåhraeus discovered the decrease in the apparent viscosity of blood in small tubes, but failed to induce blood to flow through tubes as small as arterioles because they became blocked with agglutinated red corpuscles. Bayliss, with micropipette technique and with defibrinated blood from heart–lung preparations which agglutinates less, was able to measure the apparent viscosity in blood flowing in 20μ glass tubes, that is, arteriole size, and found it about one-half that when the same blood passed through tubes of 500μ diameter or more. The paper describing this was refused for publication, presumably because the conclusion was so unlikely or perhaps because physiologists would not understand it. It remained in his drawer for a decade or more. Bayliss was always reluctant to publish. The conclusion leaked out as a 'personal communication' in a paper on the apparent viscosity of blood in hind limbs (1933) in which arterioles are about the same size, 20μ, and form the main resistance to the flow of blood. Happily, the apparent viscosity in hind limbs was the same as that in Bayliss's small glass tubes.

The anomalous viscosity of blood was attributed by Fåhraeus to axial concentration of the cells which slipped, as an almost solid rod, through nearly cell-free serum which separated the rod from the glass of the tube. Bayliss's later investigations attempted to test this hypothesis by comparing the viscosity obtained by direct measurement with that calculated from the distribution of optical density of different layers of blood flowing in microtubes when distortion due to refraction has been overcome or mathematically allowed for. His latest review on the rheology of blood is in the great *American Handbook of Physiology*, Section 2 on "Circulation" (1; 1962).

Fifty years ago, physiology had established itself as an independent science, pursued for the most part by medically qualified physiologists in the hope of increasing our understanding of normal, and to some extent disease, processes in man. Hence, many of the text-books included 'Human Physiology' in their titles, though they described, almost exclusively, experiments on animals other than man. Into this setting, Sir William, father of Leonard

Bayliss, launched his *Principles of General Physiology*, which aimed at application of physical and physico-chemical principles, rather outside the knowledge or interests of most medically qualified physiologists at that time, to the functions of cells, tissues and animals. Moreover, he ranged widely over the animal kingdom beyond the frog, cat and dog, which were the conventional objects of physiological investigation. This stirred almost explosive interest among physiologists, many of whom, from home and abroad, were welcome guests at Sir William and Lady Bayliss's hospitable house in Hampstead. Into this setting, Leonard grew up to hear much discussion and to gain practical experience in his father's private laboratory and workshop, in addition to formal education at University College School and later in Trinity College, from which he took his degree in physiology at Cambridge and then his Ph.D.

After a year as physiologist at the Marine Biological Laboratory at Plymouth, he became lecturer in physiology in the University of Edinburgh. By 1939, however, physical chemistry, physiology and experimental zoology had advanced mightily in the twenty-five years since the original publication of the *Principles*, and Bayliss resigned from his salaried post to devote himself to study so as to produce a new synthesis of the cognate parts of these subjects; this he did at his father's professional home, University College, London. The War intervened, and during these years he must have been immensely active in the Army Operational Research Group, about which he spoke with real enthusiasm (see following note).

With the shortage of university staff after the War, he became reader in physiology at University College and managed, practically single-handed, in 1946 to restart the Hons. B.Sc. course which had perforce lapsed during the war years. Having set that on its feet, he resigned in 1950 in order to have leisure to pursue his ambition to create a new synthesis in the form of the *Principles of General Physiology*. This he achieved in two volumes published in 1959 and 1960, although he had continued teaching and research in an honorary capacity much as before.

He and his wife, Dr. M. Grace Eggleton, who survives him, were a devoted couple, both working in the same department and nearly always together, either in London or at their cottage in Sussex. He was a modest, frugal and exceedingly kind person, always ready to interrupt what he was doing to discuss someone else's problem; unambitious and reluctant to publish papers, though he published quite a few about widely diverse branches of physiology from water-diuresis to action-potentials. A glimpse of his generous character appears in a quotation from his preface to the *Principles of General Physiology*, 1, in the acknowledgments: "But the most valuable of all my assistance has come, whether they knew it or not, from my colleagues and students in the course of discussion and instruction". F. R. Winton

---

One morning in the autumn of 1940 I was gazing ruefully at the smoking ruins at University College, when Leonard Bayliss came and stood beside me. I had been looking for scientific people for Blackett's party at Anti-Aircraft Command and said, "Leonard, do you want a job?" The job seemed particularly pertinent then, and he said "Yes" at once. For nearly five years he worked with the Army Operational Research Group under its various titles, and was a leading member of its establishment throughout the War, contributing greatly to its success.

The efforts of this Group were of tremendous value to the A.A. Command. As General Pile wrote in his despatch (*London Gazette*, December 16, 1947), "While full credit must be given to the troops of all kinds, and indeed their conduct . . . was beyond all praise, the foundation of success was laid by the scientist, both civilian and in uniform". In his book *Ack-Ack* is a photograph of Pile talking to Bayliss, with other members of the team around.

The original party was split early into two sections: (*a*) those engaged in radar problems; (*b*) those dealing more generally with fire control and analysis. Bayliss was put in charge of the latter. A colleague of those days writes that he was "always delightfully helpful and stimulating"; and he was himself the author of many reports on A.A. gunnery, A.A. predictors, accuracy of fire against aircraft at various heights, and later against flying bombs. These were enlivened occasionally by touches of the gentle irony that his friends will recall.

It may seem remarkable that one who had no previous experience of war and its problems should have been able, immediately, to take so active and successful a part. But this does not seem so remarkable to those who knew Bayliss's breadth of knowledge and ingenuity, and his engaging readiness to help. A. V. Hill

Dr. Arvid Hjalmar Uggla

By the recent death of Dr. Arvid Uggla in his eighty-second year, the learned world has lost a great authority on everything connected with Linnæus. When Dr. J. M. Hulth of the University Library, Uppsala, published his excellent *Bibliographia Linnaeana* in 1907, he stated his intention of undertaking a work on Linnæus's manuscripts, but his promotion to the head librarianship of the University Library, Uppsala, and his early death prevented him from carrying out this project. After his service in the Swedish Army during the First World War, Arvid Uggla returned to the University Library, Uppsala, becoming one of its principal librarians. From about the year 1928, when Uggla published his first paper on Linnæus, he began a series of visits to England with the purpose of a close study of the Linnæan manuscripts. His profound study of these numerous manuscripts solved some problems long overdue. Some of these solutions were published in the year-book (*Årsskrift*) of the Swedish Linnean Society (Svenska Linné-Sällskapet) but many remain unpublished. Unlike previous research workers, he also thoroughly investigated the many manuscripts of the younger Linnæus, and was able to show that, although lacking the elder Linnæus's genius, that somewhat denigrated young man was quite a considerable naturalist. Although he prepared a valuable hand-list in manuscript and deposited a copy at the Linnean Society of London, his projected catalogue of the Linnæan manuscripts remains unpublished. It is hoped that Svenska Linné-Sällskapet will publish this catalogue as its tribute to his memory.

Only those who have made some study of the Linnæan manuscripts can form any idea of the difficulties connected with them. Apart from the fact that many of the manuscripts still consist of loose leaves (at times in doubtful order) there are the ever-present difficulties connected with reading the sometimes almost illegible handwritings. Uggla had the quick mind and keen eye necessary to do such work to perfection. In addition, he had wonderful powers of memory, which enabled him to associate immediately with other manuscripts the one he was investigating.

Apart from the numerous papers published in the *Årsskrift* and elsewhere, Uggla published several separate works. Among them, with E. Malmeström (now Bishop of Uppsala), he collaborated in a revised edition of Linnæus's several autobiographies in *Vita Caroli Linnaei* (1957).

Svenska Linné-Sällskapet devoted its *Årsskrift* for 1962, published in 1963, as a *festschrift* to Dr. Uggla on his eightieth birthday, February 13, 1963. In it will be found the reproduction of an excellent bas-relief portrait of Dr. Uggla, and a bibliography of his writings. From 1927 he was secretary of the Swedish Linnean Society and editor of its *Årsskrift*, as well as superintendent of the Linné Museum, Uppsala.

Uggla was one of the kindest and friendliest of men, and much liked by all who knew him. Although a bachelor he had great sympathy with young people, and even when very busy himself would willingly give time and effort to help others. Nevertheless, at times he could be very reserved, as if, like Browning's grammarian, he feared 'to draw a circle premature'. There is but little doubt that with him his research work came first. About two years ago he suffered a stroke, but made a good recovery. He died from heart failure on July 30, 1964.

Among the many honours conferred on Arvid Uggla were two Swedish knighthoods and the foreign membership of the Linnean Society of London. S. SAVAGE

Dr. M. Doporto

DR. MARIANO DOPORTO, director of the Irish Meteorological Service, died suddenly in Dublin on September 8.

Dr. Doporto was born in Cáceres, Spain, in 1902, and studied physics at the Universities of Madrid and Barcelona. He joined the Spanish Meteorological Office in 1921, and was in charge of the weather forecast centre at Barcelona at the outbreak of civil war in Spain. Some time afterwards he left Spain, and in 1939 joined the newly formed Irish Meteorological Service, serving first at the flying-boat base in Foynes. Two years later he moved to Dublin, and in 1948 succeeded Mr. A. H. Nagle, becoming the second director of the Service. At about the same time he became an Irish citizen.

Dr. Doporto was the author of a large number of scientific papers. His most important contributions concerned the extended solutions of the general equations of motion and the cellular structure of the atmosphere. In 1943 he deduced theoretically that an upper isopycnic layer must occur at a height of about 25 km, a prediction which was later verified. Shortly before his death, he was working on a possible association between noctilucent clouds and the isopycnic layer at 80 km.

Dr. Doporto's skill as an organizer and administrator was much in evidence in the development of the Irish Meteorological Service during the past sixteen years. He was responsible for the completion of the network of observing stations, and for the installation of laboratories dealing with atmospheric radioactivity and the chemical analysis of air and rain. He served on the Board of the Dublin Institute of Advanced Studies and took a leading part in international meteorological affairs through the World Meteorological Organization and the International Union of Geodesy and Geophysics.

Dr. Doporto leaves a widow and three sons.

P. M. AUSTIN BOURKE

NEWS and VIEWS

Automatic Data Processing in the Manchester College of Science and Technology : Prof. G. Black

DR. GORDON BLACK has been appointed to the (part-time) chair in automatic data processing in the Faculty of Technology in the Manchester College of Science and Technology. Dr. Black, who is forty-one years of age, was educated at the Warrington County Grammar School and the University of Durham. After gaining a B.Sc. degree at Durham in 1945, he worked for a short time at the Royal Aircraft Establishment, Farnborough, in the Research and Development Department, before moving in 1946 to the British Scientific Instrument Research Association. He remained with the Association until 1956 and during this ten-year period he qualified for a Ph.D (London) degree and a diploma of the Imperial College of Science and Technology, following extra-mural research extending over two years in the field of technical optics. He also spent three further years on research in association with the Computing Laboratory at the University of Manchester, working on automatic numerical optimization. He was elected a Fellow of the Institute of Physics in 1951. In 1956 he accepted an appointment as principal scientific officer with the United Kingdom Atomic Energy Authority at Risley, Warrington, working mainly on computer applications. He was appointed senior principal scientific officer in the Computing Section at Risley in 1958 and became deputy chief scientific officer (technical manager) of the Computing Section in 1959. His staff totals 60 (including 30 graduates) and he has been concerned with the operations of three computers, the *Mercury*, the IBM 704/7090, and the *PACE* analogue computer.

Professional Civil Servants

State Service for August 1964, the journal of the Institution of Professional Civil Servants, reports the debate on motions presented at the annual delegate conference, briefly summarizes the conflict between the Institution and the Ministry of Aviation over the conditions of service of Air Traffic Control Officers (into which a committee is now enquiring) and notes the protests which are reaching the Institution from professional and technical staff in the Ministry of Public Building and Works. These protests are aimed at the excessively autocratic nature of the new organization, which appears to embody the worst features of the old Ministry of Works organization. Professional officers in the new Ministry complain that administrative control now limits the freedom they formerly possessed in exercise of technical judgment in discharging their duties, while the overhead expenses of the Department are significantly greater than those of the Works Department in the old Service Ministries. The Institution also directs attention to the Treasury's resistance to the proposal that professionally qualified officers should be known simply by the title of their profession—architect, engineer, etc., instead of by the terms, 'basic' and 'main', which are now meaningless inside as well as outside the Civil Service; for these terms the Institution suggests the substitution of the terms 'senior' and 'principal', respectively.

Commonwealth Scholarship Plan

THE fourth annual report of the Commonwealth Scholarship and Fellowship Plan closely follows the pattern of previous reports and again includes a special section on Commonwealth visiting fellowships and other senior awards under the Plan (Pp. 76. London: H.M.S.O., 1964. 5*s*.). Five senior Fellows from Britain took up awards in New Zealand, Australia, India (2) and Canada. Four from Australia visited Britain (2), Canada and India; two from New Zealand took up prestige fellowships in Britain, one from India in Canada, and one visitor's award from Southern Rhodesia enabled an adviser to visit Australia. Awards held in the first terms of the academic year increased from 820 in 1962–63 to 924 in 1963–64. Britain has now reached her target figure and both Canada and Australia have nearly achieved theirs. Jamaica offered her first scholarship, tenable at the University of the West Indies, and, with one exception, all the countries which promised to institute awards have now done so. Of the 390 scholarships taken up during the year, 219 were awarded by Britain, 84 by Canada, 26 by Australia, 22 by India and 13 by the West Indies. Although the Plan appears to be working effectively and making a real contribution to the educational needs of the Commonwealth, there are some difficulties. Perhaps

the most important is that of attracting strong fields of applicants for awards offered by the less-developed Commonwealth countries. This is primarily a question of publicity, and the report stresses the need for accurate, detailed and up-to-date information regarding facilities in the universities of these countries. Reference is again made to the shortage in some countries of graduates eligible to apply, and some of these countries are urging more awards at undergraduate level. There is also the recurrent difficulty of inducing some Scholars to return home on completion of their tenure, and although an appreciable number of Scholars have now returned to their home countries, of 324 whose awards had terminated by March 31, 108 sought deferment for periods of up to two years.

University Extra-mural Work in Britain

The report of the Universities Council for Adult Education, 1962–63, entitled *Change and Tradition in University Extramural Work*, notes new developments announced in broadcasting and other encouragement received from different quarters for adult education (Pp. 24. Liverpool: Universities Council for Adult Education, The University, 1964). Reports from the various extra-mural departments indicate the variety of the demand as well as the opportunities, and the intensity of the demand is illustrated by the persistence with which the courses were pursued during the severe winter that year. The increased possibility of planning classes on a regional basis is emphasized in some of these reports, as well as the possibility of a new local pattern of extra-mural classes, with a choice of subjects offered in neighbouring towns. The report emphasizes also the need for adult education centres, with a varied programme, and spaced so that each can act as a centre for the region. Besides the growing momentum of day-release courses for trade unionists there is a marked spread and development of extra-mural courses for social workers. There is also a general development of extra-mural courses of groups which have a common vocational interest, illustrated by a particularly encouraging response to some courses for magistrates and the interest aroused among local authorities by a week-end conference on "Coastal Erosion" arranged by the University of Southampton. Residential courses arranged by university extra-mural departments seem likely to increase, and there is also more general adoption of linked week-end courses. The increased need for extra-mural departments to provide facilities for training and research in adult education is again stressed, but the report concludes by deploring the Ministry of Education's announcement in February 1964 that no additional grant-aid would be available in 1964–65 to finance further full-time appointments or expansion of full-time work. This reversal of policy came when the plans of extra-mural departments were already advanced. The Council firmly protests against such short-sightedness, which achieves trifling economy but frustrates and stultifies the efforts of extra-mural departments to respond to the growing public awareness that education is a life-long process in which the universities have a recognized and continuing part to play.

Teaching and Research in Public Health Engineering

A two-day conference of "Teachers of Public Health Engineering in Universities and Colleges of Technology" was held at the Imperial College of Science and Technology, London, during September 17–18. This followed a successful first meeting held in the University of Newcastle a year ago. It was attended by participants from the Universities of Birmingham, Leeds, London (Imperial College and University College), Newcastle, Sheffield and Strathclyde, and from Kingston College of Technology, Manchester College of Science and Technology, and the National University of Ireland. Discussions on the first day were devoted to the teaching of public health engineering at both undergraduate and postgraduate levels, the recruitment and selection of students, the provision of short courses on specific topics and assistance to universities overseas. On the second day the conference discussed a number of subjects of current research or of possible future research. Among these were various aspects of water conservation, including investigations on the economic optimization of water and sewage treatment processes, tertiary treatment of sewage, some possible new methods of waste treatment and the application of chemical engineering processes in the field of public health engineering. There was also discussion on the presentation of the results of research and on co-operation with other research bodies. It was agreed that a further meeting should be held in the University of Strathclyde, Glasgow, in September 1965.

Fourth World Congress on Industrial Safety

This year the Royal Society for the Prevention of Accidents, in co-operation with the International Labour Office and the International Social Security Association, has organized, and is host to, the Fourth World Congress on Industrial Safety. To mark the occasion, the *British Journal of Industrial Safety* (**6**, No. 68; Summer 1964) devotes a whole issue to contributions made by some sections of British industry towards the greater safety and health of their employees. It is gratifying to know that "The United Kingdom is proud of its contribution to industrial safety. Its statutory provisions have been used by other countries as a blueprint for their own laws, and many of its industries have established safety programmes which have achieved creditable results over the years". After a foreword by R. K. Christy (H.M. Chief Inspector of Factories), the titles of contributions are: "There is no Profit without Safety", by G. H. Beeby (chairman, British Titan Products Co., Ltd.); "Research for Health: Work on Pneumoconiosis", by Dr. R. L. Gordon (Safety in Mines Research Establishment, Ministry of Power); "Accidents in the Construction Industry", by D. Short (H.M. Senior Inspector of Factories, Building and Civil Engineering); "Safety through Standards in British Industry", by R. Berry (divisional chief technical officer, British Standards Institution); "The Practice of Medicine in Industry", by Dr. R. Murray (medical adviser to the Trades Union Congress); "Safety in Steel", by R. Barry (head of Accident Prevention, British Iron and Steel Federation, and editor of *Safety*); "Safety in Chemicals", by N. F. Patterson (chairman, British Chemical Industry Safety Council); and "Accident Prevention in the Rubber Manufacturing Industry", by H. Jackson and S. F. Smith (respectively deputy chairman of the Leyland and Birmingham Rubber Co., Ltd., and chief officer for safety, health and welfare, the Dunlop Rubber Co., Ltd.). Each year, in conjunction with the National Industrial Safety Conference, the Royal Society for the Prevention of Accidents organizes a trade exhibition of industrial safety equipment. It was appropriate that this year the 'Intersaf' Exhibition was staged in London (July 13–17) to coincide with the fourth World Congress on the Prevention of Occupational Accidents and Diseases.

Mobile Foundry Laboratory

Among many matters of interest mentioned in the annual report of the British Non-Ferrous Metals Research Association for 1963 is the description of a travelling laboratory designed to assist the non-ferrous foundry industries (Pp. 47. London: The British Non-Ferrous Metals Research Association, 1964). An 18-ft. caravan is fully equipped to demonstrate techniques, and is staffed by a metallurgist especially experienced in foundry matters and a highly qualified technician. Established especially to assist those producing copper alloy castings, it is already making a considerable impact on this branch of industry (see also p. 308 of this issue of *Nature*).

Future of Chemical Publications

A DISCUSSION meeting on "The Future of Chemical Publications", organized by the Chemical Society, was held at the University of Nottingham during September 22–24. It was attended by about 190 people drawn equally from those concerned with practical chemistry and those engaged in administration or information work. About 18 months ago the Chemical Society appointed Dr. R. S. Cahn, who was then its editor, to conduct a survey of chemical publications that should be embodied in a report containing recommendations for action by the Chemical Society in the immediate and the not so immediate future; the report is to be submitted not later than Easter 1965 and it is the Chemical Society's hope to publish it. The objects of the discussion meeting were to place before interested British chemists some details of the present situation and the lines along which Dr. Cahn as director of publications research for the Chemical Society was thinking, as well as to solicit opinions and suggestions from the audience. Principal papers were read by Prof. J. S. Anderson (Oxford) on "The Scientific Urgency", Dr. R. S. Cahn on "The Future of Primary Publications", and Dr. F. A. Tate (assistant director and acting editor of the Chemical Abstracts Service, Columbus, Ohio) on "The Chemical Abstracts Service: Present and Future". Shorter papers were contributed by Dr. L. C. Cross (editor, the Chemical Society), Prof. W. G. Overend (honorary publications secretary, Society of Chemical Industry), Prof. J. D. Bernal (Birkbeck College, London), Mr. C. M. Hutt (Academic Press, Inc. (London), Ltd.), Dr. H. J. Rogers (chairman of the editorial board of the *Biochemical Journal*), Mr. J. H. Black (Library and Information Department, Shirley Institute, Manchester), Mr. Allen J. Sprow (National Science Foundation, Washington, D.C.), Dr. H. T. Hookway (Department of Scientific and Industrial Research), Dr. R. E. Fairbairn (Imperial Chemical Industries, Ltd.), Dr. M. P. Barnett (Institute of Computer Science, London) and Dr. H. Coblans (Association of Special Libraries and Information Bureaux, London). A great deal of time was left for discussion from the floor, and many views were freely expressed about the needs of chemists and about the value of the suggestions put forward by the speakers. No firm conclusions were reached or sought at this meeting, but, as intended, most of those present were able to gain a deeper insight into chemical publications, while the officials of the Chemical Society gained much, ascertaining the views of chemists in regard to their varying activities.

International Support of Cancer Research

A CONFERENCE on "The International Support of Cancer Research" was held in Stockholm during September 7–9 under the auspices of the Union Internationale Contre le Cancer. The objectives of the conference were to survey present proposals for increased international co-operation in cancer research and related medicine and biology, to estimate research needs in the various regions of the world, and to make recommendations. Reports were received of the present and future requirements of cancer research in the various countries of the world. While present support of cancer research varies widely from country to country, it was concluded at the conference that an urgent need exists, additional to national support, for international support on a considerable scale, probably of the order of many millions of dollars annually. Special emphasis was placed on basic research, the extension of international investigations in epidemiology and demography, and programmes of scientific and technical training and exchange. The conference favoured the establishment of an International Cancer Research Agency, sponsored and financed by Governments, to which the Union Internationale Contre le Cancer would make its medical and scientific contribution in concert with the World Health Organization and other organs where appropriate. The establishment was envisaged of an agency to act as recipient and manager of funds, with a Scientific Advisory Council appointed from a panel nominated by the Union. This agency would be responsible for the allocation of support on the basis of specific applications, and also from its own investigations of research requirements throughout the world. The conference considered it of special importance that such support would be accorded not only to projects transcending national boundaries, but also to intra-national projects in the case of countries not at present able to sustain these from their own resources.

International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in the *Bulletin of Zoological Nomenclature* (**21**, Part 3; August 7, 1964): (1) Designation of a type-species for *Lingula* Bruguière [1797] (Brachiopoda). *Z.N.(S.)* 1598. (2) Validation of the generic name *Axopora* Milne Edwards and Haime, 1850 (Hydrozoa). *Z.N.(S.)* 1610. (3) Validation of a neotype for *Cancer setiferus* Linnaeus, 1767 (Crustacea, Decapoda). *Z.N.(S.)* 1617. (4) Designation of type-species for *Purpura* Bruguière, 1789, and *Muricanthus* Swainson, 1840; validation of *Ocenebra* Gray, 1847; validation of Thaisidae Suter, 1913 (Gastropoda). *Z.N.(S.)* 1621. (5) Suppression of *Certhia chrysotis* Latham, 1801 (Aves). *Z.N.(S.)* 1653. Any zoologist who wishes to comment on any of the foregoing cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S.W.7, before February 7, 1965.

Isidore of Seville

FROM the time when the Roman Empire was converted to Christianity, that is, from A.D. 400 until A.D. 1200, the surviving remains of classical learning and science were preserved in monasteries, where manuscripts were treasured, valued and written. Of the many writers of the period the most learned was Isidore of Seville or Isidoreus Hispalensis (570 ?–636). He was born either at Seville or Carthagena and became Bishop of Seville, the premier Catholic See in Spain, in 599. The canons of the Councils at Seville in 618–19 and at Toledo in 633, during his episcopate, formed the basis of the constitutional law of Spain. Isidore was a voluminous writer and widely read in classical authors. He wrote an introduction to the Old and New Testaments, a defence of Christianity against the Jews, three books of *Sentences*, books on ecclesiastical offices and monastic rules, and a history of the Goths, Vandals and Suevi. The works of most interest to scientific historians are *Etymologiae* (edited by W. M. Lindsay, 1912) and *De Natura Rerum*. The former was an encyclopædia of the then known sciences. In a recent monograph (*Isidore of Seville: The Medical Writings*. An English translation with an Introduction and Commentary, by William D. Sharpe. *Trans. Amer. Philos. Soc.*, Philadelphia (pp. 75), N.S., **54**, Pt. 2, 1964). Dr. W. D. Sharpe has translated the medical writings in the *Etymologiae* into English, and has made a careful examination of Isidore's sources for his compilation (including late Latin medical literature) and of the work itself. He points out that this part of the encyclopædia was written for amateurs of medicine rather than for professional physicians. Use was made of it by Bede, Alcuin, Rhabanus, Maurus and Vincent of Beauvais. In manuscript copies the *Etymologiae* enjoyed wide popularity during the Middle Ages, and was often reprinted during the first century after the invention of printing.

U.K. Honours Courses in Mathematics

A PAMPHLET on honours courses in mathematics in the universities of Great Britain, prepared by A. P. Rollett, was published in 1963 by the Association of Headmasters and the Association of Head Mistresses (*Honours Courses in Mathematics in the Universities of Great Britain*. Pp. ii+61. London: Incorporated Association of Headmasters, 1963. 3*s*. 6*d*.). In this, those honours degree courses which required mathematics as at least one-half of the course were described, with notes on entrance qualifications and an informative general introduction. This guide has already proved its worth in helping the prospective undergraduate to discover those universities which are offering courses most suited to his or her particular aptitudes and tastes, while the introduction does something to help him to bridge the gap, always tending to widen, between school mathematics and university mathematics. A first supplement, compiled by W. J. Langford, has now been issued, in which details of courses available in the ten colleges of advanced technology are given, and alterations and additions to the 1963 university information are noted (*Honours Courses in Mathematics in the Universities and Colleges of Advanced Technology in Great Britain, Supplement No. 1*. Pp. 28. London: Incorporated Association of Headmasters, 1964. 1*s*. 6*d*.). The usefulness of these signposts to a somewhat tangled domain is beyond question. It is good to know that new editions may be expected in 1965, and that information about courses in regional technical colleges and in training colleges may then be included.

New Labelled Compounds from the Radiochemical Centre, Amersham

OF the radioisotope preparations available for blood cell labelling, di-isopropylphosphorofluoridate-^{32}P is considered by many workers to provide most nearly the qualities of an 'ideal' label; it appears not to elute, does not produce measurable cell damage and is not re-utilized. The Radiochemical Centre, Amersham, has now made available a sterile solution in propylene glycol. The solution cannot be heat-sterilized because of thermal instability and reaction with the solvent, but γ-irradiation has been successfully adopted as the sterilization process. It is supplied in the following forms:

Packaging	Price
Ampoules containing 200 μc. in 1-ml. propylene glycol	5 ampoules (1 mc.) £15; 10 ampoules (2 mc.) £25; then £10 per 5 ampoules
Penicillin-type bottles containing 1 mc. in 5-ml. propylene glycol	1 bottle (1 mc.) £12; then £8 per bottle
'Clinbritic' vaccine bottles containing bulk solution at 200 μc. per ml.	1 mc. £12; then £6 per mc.

The following compounds have been introduced since the issue of the Radiochemical Centre *Supplementary List* No. 1: DL-adrenaline-7-*T*; allyl isothiocyanate-^{35}S; carbaminoylcholine(methyl-^{14}C) chloride; dimethyl sulphoxide-^{35}S; dodecane-1-thiol-^{35}S (dodecyl mercaptan-^{35}S, lauryl mercaptan-^{35}S); iodinated polyvinyl pyrrolidone-1125, sterile solution; œstradiol-4-^{14}C (benzene/2 per cent methanol solution); œstrone-4-^{14}C (benzene solution). Further information can be obtained from the Radiochemical Centre, Amersham, Bucks.

Codes of Practice on Prestressed Concrete

THE ever-increasing use of prestressed concrete in building and civil engineering in the United Kingdom and in most European countries stems largely from interchange of ideas and the results of international research. Codes of practice and specifications may, and often do, vary from one country to another, and contractors and engineers concerned with overseas contracts must necessarily have prior knowledge of such variations. As a practical means of collating information on this subject from different sources, not only for builders and civil engineers, but for all those concerned with design and construction in prestressed concrete, translations of the present-day specifications and codes of practice operative in different European countries are available (*Codes of Practice on Prestressed Concrete*. Nos. 1–7. London: Cement and Concrete Association. 20*s*. each). Of this valuable series, seven are now available: No. 1 (Germany), *Prestressed Concrete: Code of Practice for Design and Execution* (Version of October 1953, *DIN* 4227); No. 2 (Belgium), *Code of Practice for the Use of Steel in Prestressed Concrete Structures* (December 1960, document 215/4); No. 3 (Holland), *Directives for Prestressed Concrete* (Amsterdam, Stuvo, 1962); No. 4 (Austria), *Directives for the Design and Construction of Prestressed Concrete Structures* (Wien, Bondi and Sohn, 1960); No. 5 (Switzerland), *Standard Specifications relating to Concrete, Reinforced Concrete and Prestressed Concrete Structures* (Zürich, Société Suisse des Ingénieurs et des Architectes, 1956); No. 6 (Poland), *The Design of Prestressed Concrete Structures* (Konstrukcje z betonu Sprezonego, Warsaw, 1957); No. 7 (Finland), *Code of Practice on Prestressed Concrete* (Helsinki, Rakennusinsinööriyhdistys r.y., 1958).

Coal Research in Australia

THE Division of Coal Research, Commonwealth Scientific and Industrial Research Organization (Chatswood, New South Wales), publishes periodically a useful bulletin, *Coal Research in C.S.I.R.O.*, to provide ". . . an outline of the investigations in progress at the laboratories at North Ryde". A recent issue (No. 23; July 1964. Melbourne) emphasizes the importance of research into processes offering new potential methods for utilization of certain by-products of coal carbonization in gasworks and steelworks. It is noted that profitable disposal of by-products of coal carbonization has hitherto played an important part in the economics of this process, including coke in the case of gasworks, but due to the rapid growth and competition of the petrochemical industry, such disposal in recent years is becoming increasingly difficult. Changes in the pattern of chemical manufacture due to this cause are to-day world wide. The papers in this issue include "Predicting Coke Strength"; the theme here is that ". . . it would be of immense assistance to coke-oven operators to be able to make accurate predictions of coke strength based solely on the characteristics, as measured in the laboratory, of the coal being carbonized. This article suggests a basis for making such predictions". Another paper, on improving the flow properties of road tars, describes how, by suitably treating coal tars, ". . . relatively low-cost road binders can be prepared which in certain important respects are at least equal to the petroleum bitumens now being used as binders in the construction of all-weather sealed roads". D. J. Williams contributes an article on oxidation of sulphur dioxide in combustion processes, wherein it is shown that in the oxidation of sulphur dioxide to the trioxide in combustion gases, of the active intermediates involved, the role of atomic oxygen appears to be the most important. The porous structure of solid fuels influences their behaviour in combustion and gasification; an article on surface-area measurements describes a method of surface-area determination based on measurements of the adsorption of xenon and krypton. An article on the structure of low-temperature tars deals with tars derived from low-temperature fluidized carbonization of coal, for which, up to now, there has apparently been little commercial outlet. This article discusses an investigation involving both physical and chemical techniques, ". . . whereby existing knowledge of the average compound-type composition of such tars has been extended further into the high-molecular-weight range, thus bringing one stage nearer the possibility of utilizing tars for a wider variety of purposes than at present". The issue concludes with a short paper on tars from the Onia-Gegi gasification process. The inclusion of abstracts of some recent C.S.I.R.O. research papers is a useful guide to other work on coal utilization carried out by this Organization.

Plants of the Scottish Lower Carboniferous

Transactions of the Royal Society of Edinburgh, **66**, No. 1: "On the Structure of Some Petioles Associated with *Rhetinangium* Gordon" represents one of a series by Mr. A. G. Long on the plants of the Scottish Lower Carboniferous (Pp. 8+2 plates. Edinburgh: The Royal Society of Edinburgh, 1964. 6*s*.). We formerly knew very little about plants of this age, but now, thanks as much to Long as anyone, we have something like half knowledge of a considerable number, and very strange some of these plants are. In this paper, Mr. Long describes some petioles and petiole branches as a new species, but he thinks they belong to the stem *Rhetinangium* described fifty years ago. What is perhaps of more significance, he finds that the peculiar seeds *Genomosperma* are repeatedly associated with the petiole fragments. Thus, something approaching a whole plant begins to emerge, though still obscure and indeed insecure. Even such a synthesis is very remarkable with the infrequent and scattered fragments that constitute this flora.

Orientation of Stone Monuments and Buildings of Antiquity in the Near East

RECENTLY it has been suggested that many of the great stone monuments and buildings of antiquity were erected as calendars, being carefully orientated in respect to the Moon or some other heavenly body. A study of certain *Ziggurats* by G. Charrière, in the near east, would appear to confirm this suggestion (*Revue D'Assyriologie et Archéologie Orientale*, "L'Orientation de Quelques Ziggurats et Sanctuaires du Moyen-Orient" *RA* 58—1964). The article in question gives a detailed account of a number of examples such as the Moon palace of Sargon, the Ziggurat of Ur and certain Egyptian sanctuaries. Among an agricultural people the relationship between the calendar and religion is necessarily close, and this is often reflected in the orientation of their monuments.

Perkin Centenary Awards, 1965–1966

APPLICATIONS for the award of Perkin Centenary scholarships are invited by the Perkin Centenary Trust. Awards, tenable for one or two years and renewable for a further year at the discretion of the Trustees, are offered to candidates employed in an industrial firm or other institution concerned with the manufacture or the application of colouring matter, for study at a university or technical college. Two types of award are available, some to the value of £100, which are to be used in conjunction with a local education authority grant, and others to a value of £400, which are intended for students whose normal grant, inclusive of fees, would be less than about £300. Perkin travel grants are also available to teachers concerned with the study of any aspect of the manufacture or the application of colouring matter. Applications for the scholarships must be made by May 1, 1965, and for the travel grants by December 1, 1964. Further information can be obtained from the Secretary, Perkin Centenary Trust, c/o The Chemical Society, Burlington House, London, W.1.

The Night Sky in November

NEW moon occurs on Nov. 4d 07h 17m U.T. and full moon on Nov. 19d 15h 43m. The following conjunctions with the Moon occur: Nov. 13d 02h, Saturn 3° N.; Nov. 19d 04h, Jupiter 2° N.; Nov. 26d 16h, Mars 3° S. Mars is in conjunction with Regulus on Nov. 4d 01h, Mars being 1·3° N., Mercury with Antares on Nov. 14d 12h, Mercury being 2° N., and Venus with Spica on Nov. 18d 08h, Venus being 4° N. Mercury is too close to the Sun for observation. Venus is a morning star, rising at 3h 15m, 3h 55m and 4h 45m on November 1, 15 and 30, respectively. Its stellar magnitude is −3·5; its distance from the Earth increases during the month from 108 to 125 million miles and the visible portion of the apparent disk from 0·765 to 0·848. Mars rises at 0h 05m, 23h 50m and 23h 30m at the beginning, middle and end of the month, respectively. Its stellar magnitude is +1·2 and its distance from the Earth on November 15 is 140 million miles. Mars is in Leo throughout the month. Jupiter is above the horizon virtually all night, rising at sunset on November 12. Its motion is now retrograde near the boundary between Taurus and Aries, it is in opposition on November 13, its stellar magnitude is −2·4, and its distance from the Earth at opposition is 372 million miles. Saturn sets at 0h 15m, 23h 20m and 22h 20m on November 1, 15 and 30, respectively. It is stationary in Aquarius on November 2, after which it resumes its eastwards motion among the stars. Its stellar magnitude is +1·0 and its distance from the Earth on November 15 is 895 million miles. Occultations by the Moon of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 9d 16h 46·9m, ψ Sgr. *m*.(*D*); Nov. 18d 01h 41·2m, ξ^1 Cet. (*D*); Nov. 20d 21h 53·0m, ι Tau. (*R*); Nov. 21d 05h 21·5m, 109 Tau. (*R*); Nov. 21d 19h 20·6m, 1 Gem. (*D*); Nov. 21d 20h 11·0m, 1 Gem. (*R*). An occultation by Mars of *B.D.* +19° 1559 (mag. 7·4) has been predicted, Nov. 23d 03h 36m (*D*), Nov. 23d 03h 41m (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Taurid meteors are active during October 26–November 16, with maximum between November 1 and November 9. The radiant is near R.A. 3h 36m, Dec. +14°, and conditions for observation are favourable. The Leonid meteors are active during November 14–17, with maximum on November 16. The radiant is near R.A. 10h 08m, Dec. +22°, and conditions for observation are favourable.

Announcements

PROF. M. G. KENDALL has been elected president of the Institute of Statisticians in succession to the late Lord Beveridge, who was founder president of the Institute. Mr. R. Brech, formerly honorary secretary, has been elected chairman in succession to Prof. G. A. Barnard, who retired at the end of his term of office. Mr. F. D. K. Liddell has been elected honorary secretary.

MR. AUSTIN BOURKE, assistant director of the Irish Meteorological Service, has been appointed director of the Irish Meteorological Service in succession to the late Dr. M. Doporto (see p. 329 of this issue of *Nature*). Mr. Bourke is at present vice-president of the International Society of Biometeorology.

A SYMPOSIUM on pulse radiolysis will be held in Manchester, jointly by the Department of Chemistry of the University and the Paterson Laboratories, Christie Hospital and Holt Radium Institute, during April 21–23, 1965, immediately preceding the Miller Conference. Further information can be obtained from Dr. M. Ebert, Paterson Laboratories, Christie Hospital and Holt Radium Institute, Withington, Manchester 20.

THE following Acorn Meetings are to be held at the Arthur D. Little Research Institute: "The Interaction of Slow Electrons with Molecules" (November 16); "Organometallic Research in Industry" (December 7); "The Sleeping Brain" (January 11, 1965); "Solar Radiation—A Meteorological Cinderella" (February 8, 1965); "The Matchbox Pole-balancer—A Computer Programme which Learns by Trial and Error" (March 22, 1965). Further information can be obtained from Dr. R. E. Lister, Arthur D. Little Research Institute, Inveresk Gate, Musselburgh, Edinburgh.

CORRIGENDUM. In criticizing the illustrations in *Animal Worlds*, by Marston Bates (*Nature*, **203**, 907; 1964), Dr. L. Harrison Matthews stated that a photograph labelled "living zoo-plankton" is manifestly a preserved dead sample. The sample was, in fact, merely narcotized and was thus still living.

INDUSTRIAL RESEARCH IN BRITAIN

*RESEARCH for Industry, 1963** reports briefly on the progress made by nine research associations the grants of which were reviewed during the year. The British Coke Research Association's investigations of the conditions necessary for improving the quality of coke from a medium-quality coking coal, such as will be carbonized in increasing quantities, have already led to improvements in the consistency and quality of the coke by controlling the bulk density of the charge, adjusting the size and water content of the coal, and admixing small amounts of oil. By adding three different materials to poor coking coal, the physical properties of the coke have been improved sufficiently for it to be suitable for use in blast furnaces. Investigations on foundry coke, in collaboration with the British Cast Iron Research Association, have indicated procedures extending the range of coke suitable for foundry use, and a major achievement in the domestic field has been the demonstration that certain additives give a coke of improved reactivity. Fundamental investigations of the thermal behaviour of coal and the fissuring of coke promise to illuminate the process of fissure formation during carbonization of coal in coke ovens.

Fundamental work by the Research Association of British Flourmillers has included investigations of the amino-acid composition of the total protein of different types of flour, comparison of the individual fractions of the protein and an examination of the interrelation of the disulphide and thiol groups. A new family of at least six anti-oxidants has been isolated from oats and wheat, and development of the air classification of flour continued. Replacement of at least 25 per cent of the malted barley by a low-protein English flour has given beer with a better head and keeping properties. The Fruit and Vegetable Canning and Quick Freezing Research Association has continued its investigations of the heat-resistance of micro-organisms which might be present in the canned products before heat processing. Its work on the chemistry of processed peas in relation to texture is nearing completion, and a survey is being made of the extent of contamination of quick frozen foods by various types of bacteria.

The Gelatin and Glue Research Association has initiated an investigation of the fine structure of collagen and has prepared many derivatives of gelatin and animal glue by substitution of the amino-groups present. Methods have been evolved for determining the degree of substitution, and also for increasing the cross-linkability of certain bone glues. Extra-mural support is being given to an investigation at Cambridge on the ultra-centrifugation of gelatin gels, and there has been further investigation of the effect of maturing conditions on their melting-point and rigidity. As a result of work by the Heating and Ventilating Research Association, together with that of other organizations, the factors conducive to large fuel savings in modern light-weight structures are now known at least qualitatively, and a simple approximate means of sizing the plant is being developed. A simple method of noise-rating has been specified which will enable manufacturers of ventilating and air-conditioning equipment to give the fan-noise output in identical form. The Association is also examining the ventilating and air conditioning of operating theatres.

Research by the British Hydromechanics Research Association on fluid sealing is concentrated on the mechanical or face seal, on moulded seals for reciprocating shafts, and on soft packings for stuffing box glands. Work on centrifugal pumps has involved use of a mathematical model in clarifying the nature of the fluctuating forces and of electrolytic tank methods for determining perfect fluid flow patterns in pumps, while a digital computing method has been used as an alternative to a graphical one for the analysis of complicated pumping systems. The basic engineering principles in the use of oil hydraulic machinery for transmitting mechanical power are being investigated and further model tests have been made on hydraulic problems in the pipe-work systems of the cooling-water circuits of large power stations. In a different field of industry, the 'Lacra' brass bobbin winder developed by the Lace Research Association is being satisfactorily used in Leavers lace factories, and a method has been devised to speed up that part of the process of removing floats or 'clips' from lace which is still carried out by hand, and to mechanize the final removal of the floats.

The Rubber and Plastics Research Association has made fundamental contributions to the theory of polymer molecule distribution and network formation and is able to record noteworthy progress in its investigations of the effect of water on unstrained glass-reinforced plastics. The British Ship Research Association, which for five years from April 1, 1963, was awarded a minimum grant of £300,000, subject to a maximum of £500,000 with a further £200,000 on the basis of £1 per £1 on special contributions from ship owners and managers, continued full-scale trials of turbine machinery and investigated in several ships the cause of the deterioration in performance with time in service. Investigation of the increased wear of cylinder components associated with burning heavy residual oils indicates that an increase in cylinder liner temperature is most beneficial if the temperature is increased at the coolest portion of the liner. Problems of nuclear ship design, construction and operation are being investigated by a special team.

THE ROCKEFELLER FOUNDATION

THE statement on future programme and policy issued last autumn by the Rockefeller Foundation described five principal interrelated areas in which the Foundation expects to concentrate its efforts during the immediate future. It is with these five areas that the first part of the president's review for 1963 "Promise and Progress" is mainly concerned, and, dealing first with the conquest of hunger, Dr. J. C. Harrar, recognizing that private philanthropy can only play a modest part, points out that the Foundation has chosen to assist this effort through co-operative efforts in the interrelated fields of education and the medical, agricultural and social sciences*. Moreover, it not only seeks to strengthen education in

* The Rockefeller Foundation Annual Report for 1963. Pp. 319+xviii. (The Rockefeller Foundation, 111 West Fiftieth Street, New York, N.Y., 1964.)

all these sciences but also participates in rural health programmes, so that advanced agricultural technologies will accompany better health protection. The Foundation has its own programme in the agricultural and health sciences, within which it has attempted to encourage the development of extension methods and organization, but Dr. Harrar stresses the need for closer union between the social, agricultural and health sciences if the problems of backward areas are to be attacked successfully.

The Foundation's work in the agricultural sciences, which began as a single centre in Mexico directed toward improving the amount and quality of that country's basic foods, has now been extended to include similar centres in Colombia, Chile and India. In addition, two international centres have been established at strategic locations, designed for basic and applied research on food problems of major importance over a wide region. The International Rice Research Institute is a co-operative venture of the Government of the Philippines and the Ford and Rockefeller Foundations, while the International Centre for Corn and Wheat Improvement at the National School of Agriculture, Chapingo, Mexico, is operated by the Government of Mexico and the Rockefeller Foundation.

In the second field, the population problem, the Foundation will assist research in fields relating to human fertility, such as the physiology of reproduction, endocrinology, human genetics, the biochemical effects of diet, etc., as well as in demography and cultural attitudes. It will also support pilot operations in areas where population density is an especially difficult problem and where there is a desire for help. In 1963 the Foundation contributed substantially to the establishment of a Centre for Population Studies at Harvard University, and its interest in rural health centres includes investigation of family planning.

In the third area, that of strengthening emerging centres of learning, Dr. Harrar exemplifies the Foundation's policy by the support given to the University of Valle, which is already internationally important in several areas of medicine, and which in 1963 the Foundation assisted with investigations of the business and financial aspects of the University's administration, the provision of basic teaching materials, and the construction of a new building for the humanities and linguistics departments. The University of East Africa received grants for research and training in economic development, and for the Faculty of Agriculture: the University of Ibadan was helped in the creation of a Department of Psychiatry, Neurosurgery and Neurology, and also in establishing a virology research unit to study the tropical fevers of West Africa which had not been diagnosed, while the University of the Philippines received substantial grants for faculty research in the Department of English and Comparative Literature, History, Political Science and Sociology and for training and research in economics and agriculture.

In the fourth area, the Foundation is making Negro education a main programme, with considerable emphasis on higher education. A substantial contribution to the United Negro College Fund will help to strengthen the faculty and improve the equipment of 32 predominantly Negro colleges, while besides appropriating funds to assist qualified undergraduates at Duke, Emory, Tulane and Vanderbilt Universities, the Foundation has made a grant to the Woodrow Wilson National Foundation to enable Fellows to teach for a year at some 40 southern colleges, mostly predominantly Negro. In the fifth area, aiding the cultural development of the United States, Dr. Harrar cites two grants made during the year to help raise standards of excellence in the theatre.

In the second part of his review "People for Progress", Dr. Harrar describes the way in which the Foundation uses its fellowship programme as part of a training programme, linked with the establishment or reinforcement of local institutions of education and research, and the strengthening of national agencies responsible for putting new methods and materials to use. The 276 new awards in 1963 brought the total of current fellowships and scholarships to 709, of which 218 were in agricultural sciences, 191 in humanities and social sciences, and 200 in medical and natural sciences. The Fellows and Scholars came from 52 countries and an additional 93 fellowships from Foundation funds were administered by other organizations, including 12 by the Medical Research Council, 22 by the Population Council and 59 by the Social Science Research Council. Appropriations for these activities totalled 3·525 million dollars, and 3·625 million dollars has been appropriated for fellowship awards in 1964.

Considering first the provision of trained man-power for health services, Dr. Harrar notes that in Latin America the supply of physicians is reasonably adequate and the output sufficient to establish a reasonable cadre of doctors for medical care and health services. Nurses, sanitary workers and technicians are scarce and are likely to remain so. Accordingly, at the University of Valle a programme for training auxiliary community nurses is under way and in the Candeleria pilot centre comparative studies are being made to determine how much care and preventive service one resident can provide when supported by a first-class medical centre within reasonable distance. In Africa, however, the number of indigenous physicians and auxiliaries is very small and the task is to maintain the high-level clinical training while inserting into a crowded curriculum sound field training in running a dispersed health service largely staffed by sub-professionals. The Foundation is attempting to help by providing staff and economic assistance to centres based on the medical faculties of the University of Ibadan and the University of East Africa, while in India the Foundation is supporting the All India Institute of Medical Science at New Delhi, with both funds and staff in a key scheme to prepare academic personnel for the burgeoning network of medical schools. The Foundation believes that it should undertake to study the problems of the proper utilization of sub-professional staff and to provide guidance for the advanced nations in their efforts to assist the development of health services in countries which need them.

Similarly, Dr. Harrar shows how the 50 per cent increase in 1963 in the funds for supporting scholarships and fellowships in agriculture to a total of 1·5 million dollars—supporting 318 students from 27 countries at 46 institutions—is directed to the conquest of hunger. Another 1 million dollars over four years has been appropriated for the International Centre for Corn and Wheat Improvement; the International Rice Research Institute, now fully staffed, expects to have 60 graduate-trainees by the end of 1964 and already has a comprehensive and integrated programme of basic and applied research on all aspects for rice production. The Foundation has also assisted the establishment of the graduate school of the National School of Agriculture, Chapingo, Mexico, and the postgraduate school of the Indian Agricultural Research Institute, New Delhi, and already the increased resources of trained man-power have permitted progress in the structure and functioning of agencies concerned with agricultural advance. Dr. Harrar also reviews briefly the way in which the support of the Foundation is enabling the University of East Africa and its constituent units to respond to the call for development of leadership in Africa.

Besides the president's review, the annual report includes notes on the regional programmes, and lists the grants and study awards made during the year, together with the financial statement showing appropriations during the year totalling 37 million dollars, of which 7·3 million dollars was for the agricultural sciences, 10·3 million for humanities and the social sciences, and 6·3 million dollars for medical and natural sciences.

SPECIAL CERAMICS

THE third international symposium on "Special Ceramics" was held at the British Ceramic Research Association during July 8–10, 1964. It was organized by Mr. P. Popper and followed the pattern of the 1959 and 1962 symposia. It is interesting to note the change in emphasis of the subject matter as progress in the nuclear power industry increases the demand for ceramic fuels and as advances in aircraft engine design lead to the search for new materials to withstand more rigorous operating conditions. The four half-day sessions of the symposium dealt with the preparation of non-oxides; pyrolytics and inorganic polymers; oxides and their electrical properties; and novel fabrication techniques and prospective applications as engine components. Ample time was allowed for discussion among the 170 delegates, who came from seven countries.

The symposium was opened by Dr. N. F. Astbury, director of the British Ceramic Research Association, who briefly reviewed the activities of the Association and its history, starting from an interest in technical refractories for the steel, glass and gas-making industries, later joining with the group working on pottery research, including electrical ceramics and chemical stoneware, and incorporating a building materials division. The youngest division, established to carry out investigations on special materials for future application in high-temperature engineering, was set up some ten years ago under the leadership of Mr. Popper. The visitors were invited to tour the Association's laboratories, where the many instruments in use included an electron microscope, electron probe microanalyser, direct reading spectrograph and mass spectrometer.

The first two papers, from the Atomic Energy Research Establishment, Harwell, considered the preparation and sintering of uranium nitride as a potential reactor fuel. Its preparation direct from the oxide would have economic advantages over its preparation from uranium metal or hydride, and Dr. J. B. Morris described work that he had carried out in co-operation with K. R. Hyde, D. A. Landsman, W. E. Seddon and H. C. J. Tulloch on the carbothermic reduction of uranium dioxide in a fluidized bed, in nitrogen, the carbon being either intimately mixed with the oxide or introduced as a hydrocarbon gas. The sintering to 92 per cent of theoretical density of uranium mononitride prepared by the reaction of nitrogen with uranium powder and the effects of oxidation, compaction, etc., on the sintering were described by Messrs. J. R. McLaren and P. W. M. Atkinson. General discussion of the relative merits of nitrogen and ammonia for nitriding various elements arose. Miss S. R. Billington (Morganite Research and Development, Ltd.) spoke of the investigations that she and Messrs. J. Chown and A. E. S. White had made of the sintering of silicon carbide and the possible mechanisms for transfer of material during this process, concluding that boundary-flow is operative. Messrs. J. Henney and J. W. S. Jones (Atomic Energy Research Establishment, Harwell) reported that investigations of zirconium carbide and the Zr–C–O system, preliminary to an investigation of the U–Zr–C system, had shown the existence of a single phase from $ZrC_{0\cdot6}$ to ZrC and had revealed two distinct oxycarbide phases, occurring at compositions approximately $ZrC_{0\cdot45}O_{0\cdot55}$ and $ZrC_{0\cdot5}O_{0\cdot5}$, with closely similar face-centred cubic crystal structures and no observed superstructure.

Pyrolysis has proved a useful method of making materials with negligible porosity and therefore high strength and chemical resistance and very low permeability. The method is well suited to the production of protective coatings and can also be used to provide bulk specimens. Pyrolytic silicon carbide was discussed in two papers. Dr. I. Mohyuddin reported that his investigation with Mr. P. Popper of the conditions for deposition of thick layers (3 mm) had shown that fine-grained silicon carbide of almost theoretical density and modulus of rupture 100,000 lb./in.^{2} could be deposited on a graphite substrate at 1,400° C from methyl trichlorosilane/hydrogen mixtures. Mr. R. Moreton (Ministry of Aviation, Farnborough) found that thick coatings of silicon carbide on molybdenum and tungsten rods tended to spall or crack due to a mismatch of thermal expansion coefficients, whereas thin coatings afforded protection against oxidation. Reaction between the silicon carbide and molybdenum was the cause of eventual failure, and Mr. Moreton suggested that a molybdenum/tungsten alloy of the correct expansion coefficient would allow thicker adherent coatings and greater protection.

There is an overlap between the usual definitions of 'inorganic polymers' and 'ceramics', and the relation between these was examined by Mr. P. G. Chantrell and Mr. P. Popper in considering the potentialities of inorganic polymers (classified here as chain compounds of high molecular weight) as electrical materials of moderate temperature stability and as intermediates in the preparation of refractory materials. That this classification was not generally accepted was demonstrated by a paper by Drs. P. Eckerlin, I. Maak and A. Rabenau (Philips, Germany), entitled "$LiPN_2$: A New Type of Inorganic Polymer". Dr. Eckerlin described a crystalline compound, derived from phospham, stable up to 1,000° C in vacuum and having a tetragonal structure formed of PN_4 tetrahedra which bears some resemblance to cristobalite. Dr. B. J. Aylett (Westfield College, London) discussed silicon–nitrogen polymers similar to the well-known polymers containing –Si–O– backbones and the problems of preparation to avoid the hydrolytic instabilities normally ascribed to them. He also mentioned some of the physical and chemical properties of the polymers produced.

Methods of quoting purity figures, as well as accuracy of analysis, came under discussion when three papers on high-purity ceramics were read, the point being made that many elements are not looked for in the analyses. Messrs. K. S. Mazdiyasni and C. T. Lynch (U.S. Air Force Materials Laboratory) advocated the use of organometallic compounds for the production of ceramic powders of ultra-high purity and small particle size, films and fibres, by thermal decomposition of the vapour, stressing the wide variety of compounds available. Fine zirconia powder and adherent refractory coatings on graphite have been produced from alkoxides. The process adopted by Messrs. G. M. Garner and F. C. Cowlard (Plessey-U.K., Ltd.) for the production of high-purity alumina was to prepare aluminium isopropoxide, purify this by vacuum distillation and convert it to alpha alumina. Mr. H. Bennett (British Ceramic Research Association) reviewed the difficulties associated with analysis of alumina ceramics and gave details of possible analysis procedures for different levels of impurity.

The contribution by Dr. L. S. Williams (Commonwealth Scientific and Industrial Research Organization, Australia) on infiltrated oxide cermets was read in his absence by Mr. D. E. Lloyd. Further progress had been made in the infiltration of alumina and other oxides with silver and its alloys and in the combining of impact strength and creep resistance with thermal shock resistance, for possible application as gas turbine components. Prof. W. W. Kriegel (University of North Carolina) described how he, Hayne Palmour III and D. M. Choi had produced and

varied the properties of pore-free polycrystalline magnesium aluminate spinel, which he considered as a possible high-performance structural ceramic on account of its chemical and thermal stability and multiple {111} <110> slip systems.

Three of the papers discussed the electrical properties of alumina. Drs. T. Matsumura and M. Laubitz (National Research Council, Canada) had calculated the ionic transport number from E.M.F. measurements on an $O_2(p_1)$, $Pt/Al_2O_3/Pt$, $O_2(p_2)$ galvanic cell at temperatures 700°–1,200° C and pressures 10^{-2} – 1 atm. Dr. Laubitz reported that their results were in agreement with the work of Schmalried but disagreed with some other diffusivity measurements. This type of experiment can throw considerable light on the mechanism of grain boundary diffusion. Dr. V. Daniel (Electrical Research Association, Leatherhead) described her work with Mr. M. Rogers on the degradation of ceramic insulators at high temperatures and the effects of various electrode materials, with particular reference to the rectifying barriers formed at electrode–ceramic interfaces. Dr. A. J. Moulson had also considered, with Messrs. W. R. Phillips and P. Popper, the degradation of alumina ceramics, concentrating on measurements of the diffusion of the two commonest heater-current metals, nickel and chromium, into various grades of alumina and the effect of their oxide additions on the resistivity. Some discussion of methods of measuring high-temperature resistivity to avoid surface and apparatus effects ensued. In an investigation of the effect of heat on pure single crystals of rutile, Mr. M. G. Harwood (Mullards, Ltd.) found that the d.c. stability at 150° C was raised whereas the a.c. losses were not correspondingly improved, indicating that different centres were responsible, and that only some tri- and tetra-valent cations improved the d.c. stability.

Thermal conductivity and emissivity are of importance in high-temperature applications, and materials of low friction are required for high-temperature bearings. Dr. R. W. Powell presented some results which he and Mr. R. P. Tye had obtained at the National Physical Laboratory, using both the longitudinal heat-flow and thermal comparator methods for measuring the thermal conductivity of carbides and borides, and suggested that these should be considered as metallic alloys rather than covalent compounds. Mr. J. C. Titus-Glover described emissivity measurements at 1,500°–2,500° C made with Dr. V. Croft at the University of Sheffield using a double parabolic arc image furnace and low-resolution spectrograph with a silicon cell radiometer. At the Cavendish Laboratory, Cambridge, Drs. C. A. Brookes and M. Imai had investigated the frictional properties of reaction-sintered silicon nitride and silicon carbide. These compared well with metals and the coefficient of friction was independent of load. Surface finish was important for wear resistance.

In the session on fabrication techniques, Dr. S. Scholz described a neat hot-press that he and Dr. E. Roeder had used at the Philips Laboratory in Germany. It reached 3,200° C and 1,000 kg/cm² and accurate densification/time measurements on the small samples were recorded. Some of the limitations to hot-pressing for industrial applications have been overcome by Dr. G. S. Gruintjes and Mr. G. J. Oudemans (Philips Research Laboratories, Eindhoven), who described a new technique for continuous hot-pressing that had produced long rods of both metals and ceramics. Intense collimated plasma-electron beams of powers up to 5 kW had been obtained by Messrs. J. W. Isaacs, C. W. A. Maskell and J. D. L. Harrison at the Atomic Energy Research Establishment, Harwell, from robust, hollow cathodes without filaments, and Mr. Harrison discussed methods of controlling the energy and size of the beam and applications to the melting of ceramics.

Turning to future applications, Dr. E. Glenny's paper "Ceramics and the Gas Turbine", read by Mr. R. Smith (National Gas Turbine Establishment), attributed lack of early success in applying brittle materials in gas turbines to inadequate effort, arising from insufficient incentive, and to the failure to re-design components to suit the new materials. The usefulness of materials at present available for heat exchangers, nozzle guide-vanes and coated turbine blades was discussed. Mr. N. R. Hemming (Bristol Siddeley) spoke of the need for refractory materials combining strength, toughness, lightness and oxidation resistance for use in air-breathing ramjet engines, which could advantageously be used in hypersonic aircraft capable of speeds of Mach No. 7, where wall temperatures would rise to 2,100° C.

On behalf of the visitors, Dr. W. W. Shaver of Corning's, New York, thanked the British Ceramic Research Association for its hospitality. Following Dr. Astbury's formal closure of the symposium, the visitors were able to inspect some of the work being done at the Association's laboratories.

The *Proceedings* of the symposium will be edited by Mr. P. Popper and published by Academic Press, in the spring.

S. N. RUDDLESDEN

PHENOLICS IN NORMAL AND DISEASED FRUITS AND VEGETABLES

THE phenolic compounds of fruits and vegetables, their relationship to browning, their changes when plants are infected, and their role in resistance of plants to disease constituted the symposium topic for the fourth annual meeting of the Plant Phenolic Group of North America, at the Central Research Laboratories of the United Fruit Co., Norwood, Mass., during July 23–24.

The symposium opened with three papers on dopamine (3,4-dihydroxyphenylethylamine) based on research by the United Fruit Co. Dopamine, a major phenol in banana, is readily oxidized to form melanin. E. H. Buckley discussed the periods of dopamine accumulation, content, and distribution in banana peel and its biosynthesis via tyrosine and tyramine throughout the plant. J. K. Palmer outlined the enzymatic oxidation of dopamine to melanin by banana polyphenoloxidase (PPO) and the unique substrate specificity spectrum of banana PPO, with dopamine the most reactive by far. The inhibition of banana PPO *in vitro* was stressed. Reducing agents apparently worked by three different mechanisms, while the varied inhibition patterns of chelation agents indicated that other mechanisms were involved as well as chelation. Finally, M. E. Mace discussed the relationship between *Fusarium* wilt infection in banana roots and the phenolics present. Anatomical and histochemical investigations, as well as experiments *in vitro* and *in vivo*, were presented in support of the hypothesis that, in infected banana roots, oxidized dopamine mediates the conversion of tryptophan to indolyl-3-acetic acid. The IAA then induces localized tyloses that block the vascular elements and entrap spores, and thereby localize infection.

The first session was completed by a discussion of the anthocyanins of grapes by A. D. Webb (University of California, Davis). Only since the advent of paper chromatography has the complexity of anthocyanins in grapes been appreciated. Completely satisfactory methods for isolating the pigments in natural form are not yet available. Wines made from hybrids of *Vitis vinifera* with disease- and cold-resistant native American species of grape can be detected by chromatography; this test is of legal impor-

tance in France. *V. vinifera* fruits contain principally monoglucosides; the American varieties have, in addition, diglucosides (no other sugars have been detected). Acylated pigments are often present, with caffeic and *p*-coumaric acids as the combined acids.

A paper on enzymatic browning by J. W. Corse (Western Regional Research Laboratory, U.S. Department of Agriculture, Albany, Calif.) opened the second half of the symposium. The enzymes involved are copper-containing oxidases which are difficult to isolate and often appear to be mixtures. Molecular weights are of the order of 120,000 with perhaps four copper atoms; in some cases, the copper appears to be cuprous. The browning reaction occurs stepwise. After formation of a catechol group by introduction of a hydroxyl group, oxidation to *o*-quinones occurs. Finally, the latter polymerize non-enzymatically to dark substances, but the structure of the products is still not clear. Substrates in deciduous fruits include chlorogenic acid and related compounds. In attempts to control browning, physical methods and chemical agents have been abandoned in favour of a biochemical approach. *O*-Methyl transferase has been found to convert the catechol group to the browning-resistant guaiacyl group.

The role of phenolics in disease resistance in plants was discussed by J. Kuc' (Purdue University, Lafayette, Ind.). Increased production of chlorogenic and caffeic acids and a variety of aromatics occur both in response to disease and to wounding, the actual amount produced varying with the agent causing injury. These higher-than-normal concentrations, which are present especially on plant surface or at infection sites, inhibit microbial growth. The mechanisms by which micro-organisms bring about this increased production are varied and not yet completely understood. In general, they appear to be due to specific alterations in the metabolic pathways of both host and micro-organism. Resistance may then result from a shift in the very delicate metabolic balance.

The symposium concluded with a paper by T. Kosuge (University of California, Davis) outlining the present state of knowledge of the biosynthesis of the phenolic acids and coumarins which have been shown to accumulate in diseased tissue. Very few investigations of their biosynthesis in diseased plant tissues have been made, but considerable work has been done on healthy tissues. The acetate and shikimic acid pathways, which occur in higher plants, appear to be involved in the production of such compounds. The *Proceedings* of the symposium will be published in due course.

The officers for the Plant Phenolics Group of North America elected for the present year are: *President*, Dr. Margaret K. Seikel; *Vice-president*, Dr. Bernard J. Finkle; *Secretary–Treasurer*, Dr. V. C. Runeckles (Imperial Tobacco Co. of Canada, Ltd., Montreal, Canada).

Margaret K. Seikel

PROBLEMS OF NOISE

As long ago as 1948 the British Standards Institution published a code of practice entitled *Sound Insulation* (*Houses, Flats and Schools*) (*CP* 3. Ch. 3; 1948). It had, of course, been a problem long before this, but since the Second World War the incidence of noise, in the home, in industry and out of doors, on the human being, has grown to be a matter not only of psychological but latterly of medical concern. That code tackled the problem of noise of both indoor and outdoor origin. It was largely concerned with means of reducing noise by appropriate siting, positioning and screening of windows in buildings. It included data of noise reduction values in 'phons' for different kinds of windows, open or shut. A revised B.S. Code (Ch. 3; 1960), entitled *Sound Insulation and Noise Reduction*, followed. In the same year came the official *Noise in Factories* (*Factory Building Studies*, No. 6, H.M. Stationery Office, 1960); L. L. Beranek's *Noise Reduction* (McGraw-Hill, 1960), and a paper by D. E. Broadbent on "Effects of Noise Reduction in a Work Situation" (*Occupational Psychology*, April 1960). The last-mentioned author, who is director of the Medical Research Council Applied Psychology Research Unit, is also responsible for a more recent booklet, *Noise in Industry*, No. 6 in the series *Ergonomics for Industry*, prepared jointly by the Department of Scientific and Industrial Research Information Division and Warren Spring Laboratory*.

Undue noise is a matter which, in these modern days, affects us all in a great variety of ways, wherever we may be and whatever we are doing. On relaxed occasions it may be encouraged by certain members of the younger generation, abhorred by others more mature. But in day-to-day industrial occupations, it is quite another matter. There are three main reasons, as the author shows: ". . . people do not like it, it damages their hearing and it has a bad effect on their working efficiency". These three effects are not necessarily interrelated. As he says: ". . . a noise which is very annoying may not be loud enough to damage hearing, or make people work less well. On the other hand, there is the rather alarming possibility that noises which do not annoy people at all may quite often damage their hearing or impair their efficiency. It is important therefore to distinguish the various effects from one another and not to assume that all is well just because the workers in a noisy factory seem to be contented". Thus the theme of this booklet is to alert us to the effects, direct or more dangerously insidious, which noise may have on people at work and, it may be added, by inference in social environments where sometimes noise is cultivated for its own sake.

In modern measurements of sound, two technical terms are at present used. 'Cycles per second' (c/s) is the unit used to measure frequency. The 'decibel' (dB) measures the intensity. "The loudest sounds we may meet have an intensity of more than a million million times the intensity of the faintest sound we can hear. A scale of decibels takes this into account." The scale is logarithmic. Proportional changes in intensity are covered by the same number of units. Thus a ten-fold increase, 1–10, 10–100, 100–1,000, etc., is represented by a change of 10 dB. Impressive examples are given: 135 dB hydraulic press at 3 ft.; 105 dB train whistle at 50 ft.; 95 dB automatic lathe at close range; 75 dB office machines between desks; 65 dB speech at 3 or 4 ft.; 20 dB whisper at 4 ft.; and 0 dB threshold of hearing at 1,000 c/s. "It should also be noted that the smallest change appreciated by the ear is about 1 dB where the change is in a faint sound or in a loud sound. dB figures are usually quoted with reference to an arbitrary zero—actually 0·0002 dynes/cm²—which is approximately the faintest sound we can hear at 1,000 c/s."

This publication, although relatively brief, is convincing in its argument, supporting data, and message. The serious effects of noise on the ear, and on work efficiency, under manifold conditions, are incontrovertible. Some far-reaching conclusions from results of investigations into the hazards of noise are, cautiously, drawn by the author; among these may be cited: "The level of 90 dB is not too far from the level which has to be regarded as a threat to hearing; . . . if precautions are taken to prevent deafness, they will also tend to prevent effects on working

* Department of Scientific and Industrial Research. *Ergonomics for Industry*, No. 6. *Noise in Industry*. By D. E. Broadbent. Pp. 16. (London: H.M. Stationery Office, obtainable (free) from D.S.I.R. Warren Spring Laboratory, Stevenage, Herts, 1964.)

efficiency." "This level—90 dB—is not at all unusual in industry, but it is very much higher than the level which people often complain about in offices and other places away from the factory floor." As is common experience, undue noise makes normal conversation impossible; it is in fact difficult unless the noise is reduced well below the 90-dB level. 60 dB is considered a more reasonable level, but in an office environment, where ordinary speech is involved, the limits of noise should be much lower.

The question of noise in all its aspects, but particularly as a hazard in industry, is now a matter of national importance. It is indeed gratifying to learn that the Ministry of Pensions and National Insurance has sponsored a large-scale research project into certain aspects of occupational deafness. This is the joint problem of the Medical Research Council and the National Physical Laboratory. "The purpose of this study is to monitor hearing of people exposed to industrial noise . . . to establish the relation between noise and damage to hearing . . . to make recommendations concerning hearing-conversation measures." When it is commonly realized that effects of prolonged noise, in whatever environment, above a certain level, are real, and provocative of permanent deafness, then people may begin to take those precautions which common sense (and this booklet) suggest. Apart from this, undue and unwanted noise, especially when it intrudes into social life, public or private, without let or hindrance, is a form of annoyance which many people will not tolerate. The recent ban on transistor radio sets operating in some of Britain's royal parks is a step in the right direction, but only a beginning.

H. B. MILNER

THE LISTER INSTITUTE

THE annual report of the Governing Body of the Lister Institute* is necessarily a greatly condensed account of the varied activities of 'The Lister', and it is impossible to indicate in a brief notice the scope and detail of the research involved. The report summarizes the Institute's work under several headings.

In the field of microbiology, work continues on the genetics of bacteria, particularly *Salmonella* spp., with special regard to the transmission of drug resistance; on the specificity of the antigens of *Trypanosoma brucei* and *T. vivax*, and on the conditions governing the formation of capsules by the anthrax bacillus *in vitro*. The Institute's field studies on trachoma in the Gambia continue, together with work on the epidemiology and pathology of pleuropneumonia-like organisms and of the Shope fibroma virus in cell culture. There has been continued progress in making a non-infectious smallpox vaccine and in work on the purification of vaccinia virus and antibody immunity in vaccinia and variola infections.

Among the epidemiological studies was an important investigation, carried out in co-operation with the Malaria Eradication Division of the World Health Organization and the Veterinary Services of Southern Rhodesia, of identification tests of the blood meals of tsetse flies and *Anopheles* mosquitoes.

Immunopathological investigations are being carried out on a factor in anaphylactic tissues which induces eosinophilia; on the local production in the cervix uteri of antibodies lethal to spermatozoa, and on improvement of therapeutic antitoxins to scorpion bites.

T. brucei, which had not been previously cultured for any prolonged period, has been successfully established in a liquid medium which makes it available for immunological and biochemical studies. Other work includes investigations of the immunology of whooping cough and typhoid and the mechanism of infection with actinomycotic dermatitis of sheep. The section devoted to the physiology of bacteria includes studies of the somatic polysaccharides of S. and R. *Salmonella* and the chemistry of the flagellar proteins of *Salmonella*.

Biophysical work includes work on human plasma proteins and on the molecular characterizations of blood-group substances. The latter has led to extension and modification of existing theories for interpreting sedimentation and viscosity data. The Blood Products Laboratory continued to prepare dried plasma and plasma fractions for the National Health Service, and the Blood Group Research Unit has continued to study the Xg and the Rh systems. The Blood Group Reference Laboratory continues its work in its new building north of the Biophysics Department.

The report records the conferment of a baronetcy on the chairman of the Institute's Governing Body, Sir Charles Dodds, and the elections of Lord Iveagh and Lord Brain, both members of the Governing Body, to fellowship of the Royal Society. The death during the year of R. St. John Brooks, curator for more than 20 years of the National Collection of Type Cultures, is a great loss to the Institute and to microbiology in general. The director of the Institute, Prof. A. A. Miles, has been appointed Biological Secretary and a vice-president of the Royal Society of London. During the year the Guinness chair of microbiology was established at the Institute and Dr. B. A. D. Stocker was appointed to it.

A gift of £30,000 from the Fleming Memorial Fund for Medical Research will enable the Institute to establish its own electron-microscope unit. The new Virus Laboratory at Elstree was completed during the year and occupied by the Virus Research Unit, and the Library at Chelsea was enlarged by the addition of another room.

The report also records the lectures given by the staff in Europe and America, and concludes with a list of their numerous publications.

For details of the biochemical work on blood-group substances, cellular phospholipids and glycogen the report itself must be consulted.

MOUSE ANTIBODY PRODUCTION TEST FOR THE ASSAY OF THE MOLONEY VIRUS

By DR. EVA KLEIN and PROF. GEORGE KLEIN

Department of Tumour Biology, Karolinska Institutet Medical School, Stockholm

INOCULATION of homografts, sub-threshold isografts or tissue homogenates derived from mouse lymphomas induced by the Moloney virus leads to specific transplantation resistance against subsequent Moloney lymphoma isografts[1]. The serum of resistant mice contains humoral antibodies, demonstrable in three different ways: by passive transfer of transplantation resistance, by cytotoxicity for Moloney lymphoma cells *in vitro* in the

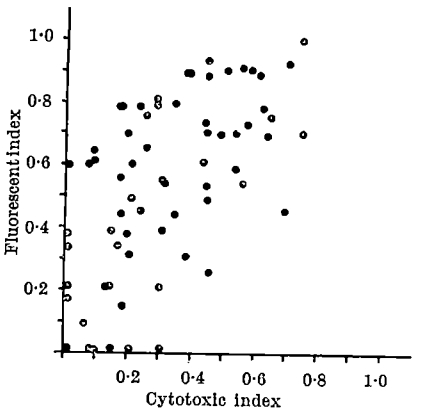

Fig. 1. Correlation between the cytotoxic and the fluorescent index given by *YAC* target cells exposed to different antisera. Only such tests are included where both tests were performed simultaneously with the same sample of target cells. Correlation data: $r = 0{\cdot}61$, $P < 0{\cdot}001$, $Z = 0{\cdot}62$, $\sigma_z = 0{\cdot}12$, $P < 0{\cdot}001$

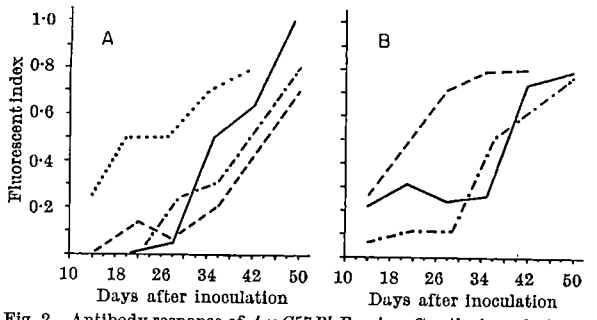

Fig. 2. Antibody response of $A \times C57Bl$ F_1 mice after the inoculation of 5×10^6 irradiated Moloney lymphoma cells, detected by the fluorescent method. *A*, ——, *YAC* sixth transfer; –·–·–·–, *YAC* eighteenth transfer; - - - - - -, *YAC* twenty-first transfer; · · · · · · · · ·, *YDAB* first transfer—Target cells *YLD*. *B*, ——, *YAA* sixth transfer; –·–·–·–, *YAA* twenty-first transfer; - - - - -, *YHA* eighth transfer—Target cells *YAA*

presence of complement, and by the indirect fluorescent antibody reaction.

The detection, identification and quantitative titration of mouse leukæmia viruses have been largely dependent on biological induction tests. The difficulties encountered with the leukæmia viruses contrast sharply against the relative ease of virus assay in systems where suitable *in vitro* techniques are available, such as, for example, in the case of polyoma. Since humoral antibodies have been demonstrated in the Moloney system by the methods mentioned here, it should be possible to develop a mouse antibody production (MAP) test for virus assay. The usefulness of such tests has been demonstrated, for example, in the polyoma system[2], and the sensitivity was comparable with the plaque assay[3]. So long as the formation of the antibodies reacting with the target cells in the cytotoxic or the indirect fluorescent antibody test is induced by the virus, it is immaterial whether they are antiviral in nature or directed against virus-induced new cellular antigens, a question that has not been clarified for this system so far[1].

The work recorded here represents an attempt to examine the feasibility of working out a MAP test of this type for the assay of the Moloney lymphoma agent.

Sera of mice inoculated with materials to be assayed for their ability to induce specific antibody formation were tested each week by the indirect fluorescent antibody method and, in a number of cases, by the cytotoxic technique as well[1]. Moloney lymphomas were used as target cells; *YAC* of strain *A* origin most frequently (4th–20th passage in ascites form), *YAA* of strain *A* origin, *YDAB* of $A \times DBA$ F_1 origin, *YHA* of C_3H origin, and *YLD* of *C57* leaden origin in a number of cases. The proportion of target cells killed in the cytotoxic test or stained in the indirect fluorescent test was expressed as a quantitative index in relation to corresponding controls incubated with control serum, as described in a previous publication[1]. Cytotoxic indexes $\geqq 0{\cdot}2$ and fluorescent indexes $\geqq 0{\cdot}3$ were regarded as positive. When the two types of tests were performed under standardized conditions, the cytotoxic and the fluorescent index increased as a function of time after the inoculation of virus-containing material. The scatter diagram in Fig. 1 shows the correlation between the cytotoxic and the fluorescent index obtained by exposing the same target cells to the same immune serum and indicates that the fluorescent method was more sensitive. A similar relationship was found when the titres given by the two methods were compared. For example, one serum that gave a cytotoxic titre of 1 : 20 against *YAC* had a 1 : 320 titre in the fluorescent test. Furthermore, while all Moloney lymphomas tested were suitable targets in the fluorescent test, some were not sensitive to the cytotoxic effect. The sensitivity of a given leukæmia varied only slightly between different cell pools in the fluorescent test, while the cytotoxic reaction was more variable. Critical comparisons between different sera of a given experimental series were always performed on the same cell suspension and at the same time. Apart from this relatively minor, uncontrollable variation, repeat tests with a given set of sera, a given target cell type, and a standard fluorescent serum or complement, resp., gave reproducible overall results in the fluorescent and the cytotoxic test as well.

Antibody response. The antibody response following the inoculation of a standard dose of X-irradiated Moloney lymphoma cells was determined for different lymphoma lines. The cells received 6,000 r. *in vitro* in order to prevent their proliferation *in vivo* which would bias the quantitation of the inoculum. Some typical experiments are shown in Fig. 2. In each group, 3 $A \times C57Bl$ F_1 male mice were inoculated with 5×10^6 irradiated cells. At different intervals, serum was collected and pooled from all three mice in each group and tested against Moloney target cells. Fig. 2*A* shows the antibody response by the fluorescence test after the inoculation of *YAC* cells from different passages and *YDAB* cells of the first passage, while Fig. 2*B* represents the reaction induced by *YHA* and *YAA* cells respectively. It appears that the time-period preceding the appearance of detectable antibody showed certain differences between the different lymphoma lines. Potent antibodies appeared earlier after the inoculation of *YHA* and *YDAB* (20–28 days) than after different transfer generations of *YAA* and *YAC* which were quite similar to each other, with antibodies appearing after

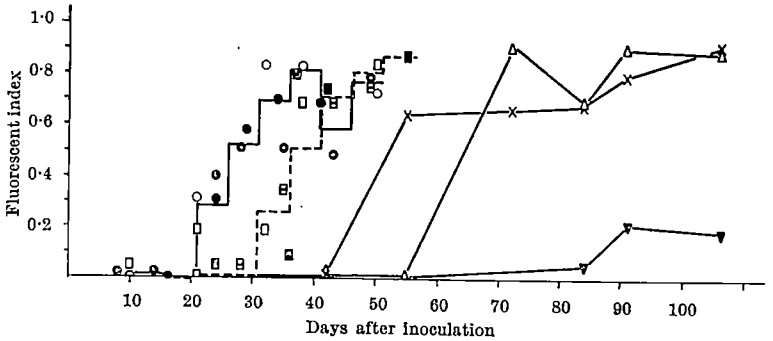

Fig. 3. Antibody response of $C3H \times C57Bl$ F_1 mice after the inoculation of virus containing homogenate, as detected by immunofluorescence. In four different experiments 0·1 ml. of 10^{-1} or 10^{-2} diluted homogenate was inoculated on day 0. In exps. 2, 3, 4 the same virus preparation was used (of $A \times DBA$ F_1 origin). In exp. 1 a different virus preparation was used of *C57* leaden origin. The mean value of the fluorescent indexes for a given virus dilution was calculated for 5 days' intervals for dilutions 10^{-1} and 10^{-2}. In addition, dilutions 10^{-3}, 10^{-4} and 10^{-5} have been included in exp. 1. These are shown in the right. Symbols: circles, 10^{-1}; quadrangles, 10^{-2}; crosses, 10^{-3}; open triangles, 10^{-4}; closed triangles, 10^{-5}. Different shadings represent different experiments

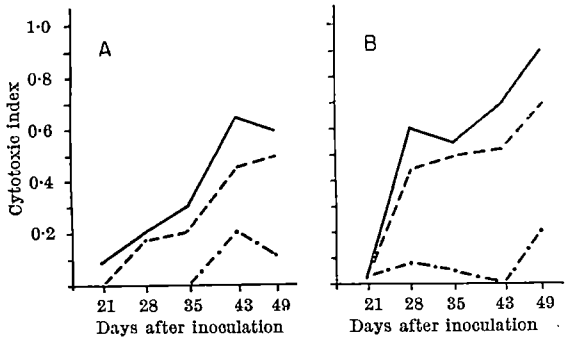

Fig. 4. Antibody response of groups of 3 *C3H* × *C57Bl* F_1 females, inoculated on day 0 with a standard virus containing homogenate (dilution: 10^{-1}). The serum pools were tested with *YAC* target cells. ——, no serum admixture; - - - - -, admixture of serum of untreated *C57Bl* × *DBA/2* F_1 mice; -·-·-·-, admixture of serum of *A* × *C57Bl* F_1 mice immunized with *YAA* Moloney lymphoma cells. *A*, cytotoxicity of serum pools in the presence of complement. *B*, fluorescent staining

35–42 days. A fifth lymphoma, *YLD*, not shown in the figures, behaved similarly to *YAC* and *YAA*. In order to examine the persistence of antibodies, mice inoculated with the same standard dose of irradiated cells from the five different lymphomas were also tested after 103–123 days. A high fluorescent index (range: 0·57–0·85) was found to persist in each case.

The maintenance of a high antibody-level during long periods of time after the inoculation of a single standard dose of irradiated, non-reproductive cells can be best interpreted by assuming that virus release and subsequent virus multiplication are responsible for the induction and persistence of antibodies. On this interpretation, all five tumour lines tested release virus, including those that have been carried through 18–22 passages, and two lines (*YHA* and *YDAB*) release larger quantities than the rest.

If the foregoing postulate is correct, inactivation of the virus should prevent antibody formation. This was tested by inoculating 5 × 10^6 cells of the *YHA* and *YLD* lines after they had been exposed to hydroxylamine[4] in order to inactivate the virus. The cell suspensions were mixed with equal volumes of 4 M hydroxylamine (*p*H 7) and incubated at 22° C for 15 min. The material was diluted 1 : 5 with phosphate buffered saline and dialysed against saline for 24 h. After inoculation, serum was collected after 7, 14, 30 and 75 days. There was no measurable antibody response.

Whether the antibodies detected are induced directly by the multiplying virus particles released by the tumour cells or by new cellular antigen(s) induced by the virus infection in the host cells cannot be decided on the basis of the present evidence.

The antibody response induced by different concentrations of the same virus preparation, preserved in the frozen state, was compared by the fluorescence test. Lymph nodes, spleen and liver of an *A* × *DBA* F_1 mouse with a primary Moloney lymphoma were homogenized in a glass homogenizer in 10 vol. of phosphate buffer and centrifuged for 20 min at 2,300*g*. The supernatant was centrifuged at 10,000*g* for 20 min and 0·1 vol. of the final supernatant were inoculated in 10^{-1} and 10^{-2} dilutions to each of 3 *C57* × *C3H* F_1 females. Three experiments were performed with the same virus pool. In a fourth experiment another homogenate, prepared from a primary lymphoma, induced in a *C57* leaden mouse, was inoculated in 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4} and 10^{-5} dilutions. The pooled sera of the three mice in each experimental group were tested against Moloney target cells by the fluorescent method at different times after inoculation. The serum samples of each experimental series were tested on two or three different occasions against different samples of target cells. The mean fluorescent index was calculated for each dilution and each point of time. After the inoculation of 0·1 ml. 1 : 10 diluted virus, antibodies were detectable after 3 weeks (Fig. 3). A ten-fold dilution of the inoculated virus delayed the response by approximately 10 days.

Neutralization tests. Experiments were also made in order to detect virus neutralizing antibodies in the serum of resistant mice by testing the effect of serum on the immunogenic ability of virus-containing homogenates. A standard homogenate was diluted 10 and 100 times and 0·1-ml. vol. were inoculated to groups of 3 *C3H* × *C57Bl* F_1 females either alone, or after the admixture of 0·05-ml. serum. The serum has been derived from untreated *C57Bl* × *DBA/2* F_1 mice or from a pool collected from 16 *A* × *C57Bl* F_1 mice immunized 6–10 times with 10^5 or 10^6 viable Moloney lymphoma cells of strain *A* origin (lymphoma *YAA*). Specific antibodies against Moloney lymphoma cells could be demonstrated in this antiserum pool by the cytotoxic and the fluorescent test as well. The virus–serum mixtures and the untreated homogenates were incubated at room temperature for 30 min before inoculation. Antibody formation is shown in Figs. 4*A* and 4*B*. The immune serum neutralized the immunogenicity of the virus-containing homogenates. Comparison with the immunogenicity of different dilutions of the same standard homogenate indicates at least a hundred-fold neutralization. Analogous findings were obtained after the inoculation of the higher virus dilution. After the admixture of immune serum there was complete inhibition of antibody formation during the entire observation period of 66 days. The virus-neutralizing ability of anti-Moloney sera was also evident when oncogenic activity was used as test criterion. In this experiment new-born *A* × *DBA/2* F_1 mice were inoculated with 0·05-ml. virus containing homogenate each, mixed with 0·025-ml. serum. The results are shown in Table 1 indicating a clear-cut neutralizing effect.

Table 1. Leukæmia induction in *A* × *DBA* F_1 mice inoculated as new-borns (< 24 h) with virus preparation treated with serum from mice inoculated with Moloney leukæmia cells. Observation period 9 months

Dilution of virus	Virus preparation mixed with Control serum: Incidence*	Control serum: Latency period (days)	Immune serum: Incidence*	Immune serum: Latency period (days)
10^{-1}	2/7	155, 192	1/23	226
10^{-2}	8/23	136, 210 208, 214 214, 218 218, 234	0/22	
10^{-3}	3/17	207, 234 239	0/16	

* Pooled serum from 15 *A* × *DBA* F_1 mice which received 5–8 inoculations of *YAA* Moloney leukæmia cells.

A number of other sera were also tested in the same way for a possible neutralizing effect. Results obtained with the 1 : 100 dilution series are exemplified in Table 2. Only the sera of mice resistant against Moloney lymphoma cells were able to neutralize the immunogenic effect of the inoculum, while anti-Gross, anti-6*C3HED* and anti-polyoma sera had no detectable effect. This is in accor-

Table 2. Effect of different antisera on the immunogenicity of Moloney-virus containing homogenates, as tested by the fluorescent antibody method. Three *C3H* × *C57Bl* F_1 mice were inoculated with the serum-homogenate mixture in each group

	Donor of serum admixed to homogenate: Genotype	Pretreatment	Fluorescent index: 21	31	40 Days after inoculation
Exp. 1	*C57Bl* × leaden F_1	—	0·12	0·35	0·55
	C3H	3 inoculations of 10^6 Moloney lymphoma cells, line *YHA*	0·09	0·00	0·03
	C3H	4 inoculations of 10^5 Gross lymphoma cells, line *GHA*	0·00	0·35	0·41
	C3H × *C57Bl* F_1	11 inoculations of 10^5 6*C3HED* lymphoma cells	0·32	0·44	0·41
	C3H	Inoculation of polyoma virus (HI titre of serum 1 : 1,840)	0·29	0·62	0·73
Exp. 2			16	24	37 Days after inoculation
	A.CA	—	0	0·07	0·68
	A.CA	10 inoculations of liver, spleen, lymph nodes of *A* animals (hæmaggl. titre: 1 : 10^4)	0	0	0·41
	A	6 inoculations of liver, spleen, lymph nodes of *A.CA* animals (hæmaggl. titre: 1 : 64)	0	0·03	0·91

dance with the findings obtained with the same types of sera when tested directly against Moloney cells[1].

The virus homogenate derived from $A \times DBA/2\ F_1$ lymphoma was also treated with *H*-2 isoantiserum against the virus-donor cell genotype on the assumption that host cell components may be incorporated into the coat of the virus particle. The results for the 10^{-2} dilution series are exemplified in Table 2, Exp. 2. There was no detectable neutralizing effect.

MECHANISM OF ENZYME CATALYSIS

By Prof. GORDON G. HAMMES
Department of Chemistry, Massachusetts Institute of Technology, Cambridge, Mass.

ALTHOUGH numerous detailed investigations of enzymatic systems have been carried out, a basic understanding of enzyme catalysis is still lacking. In particular, two fundamental questions are still unanswered: (1) Why are enzymes such efficient catalysts? (usually at least a factor of 10^6 better than the corresponding synthetic catalysts); (2) Why is a macromolecule required? The two questions, of course, are not unrelated and numerous speculations have been made. The present belief is that the macromolecular conformation is all-important, although very few specific suggestions have been put forth of a quantitative nature. The idea that conformation can control enzyme specificity is easy to understand qualitatively and was embodied long ago in the 'lock and key' hypothesis of Emil Fischer[1]. Several variations of the 'lock and key' idea are now in vogue. One school of thought believes that only a few side-chain groups are really important, and that by bringing these critical groups together in a stereospecific fashion, efficient catalysis ensues. A different variation on the same theme is embodied in the 'induced fit' theory put forth by Koshland[2], who suggests that the substrate induces changes in the protein conformation which aid in the substrate binding and catalysis. In this case the protein conformation changes in a dynamic manner throughout the course of the reaction. Eyring and Lumry[3] have suggested that the protein may serve as a 'rack' which distorts the critical substrate bonds thereby promoting catalysis. Unfortunately, none of these models can really be tested experimentally in a critical fashion. In a few cases (for example, chymotrypsin[4]) the available evidence suggests that the protein conformation does change during the course of the reaction; however, this fact is consistent with virtually all present proposals concerning the mechanism of enzyme catalysis.

The purpose of this article is to put forward some general ideas which might be of possible relevance in understanding enzyme catalysis.

In order to put the ideas presented in some sort of framework, I shall use the language of transition state theory and recall that the overall standard free energy change for a given reaction is unaffected by the presence of catalysis. Obviously, this same statement is also valid concerning the standard enthalpy and entropy changes for a particular reaction. The catalyst, however, does significantly lower the standard free energy of activation since this quantity directly reflects the efficiency of the catalytic process. Let us now consider how the enthalpy and entropy of activation may be affected by an enzyme. Both factors are undoubtedly influenced by the catalytic process although present evidence suggests that entropic effects may predominate.

Enthalpy effects. Enzymes can bring about a lowering of the activation energy in several ways. One of the most probable methods is a 'compensation' effect. By forming intermediate compounds the breaking of a bond can be facilitated; a possible way of accomplishing this is by simultaneously breaking and forming bonds. Several clear-cut examples of this phenomenon as found in elementary gas phase reactions are assembled in Table 1. For example, the activation energy for decomposition of H_2 by an inert body is greater than 100 kcal/mole, while that for the reaction $H_2 + I_2 \rightarrow 2HI$ is about 40·7 kcal/mole. Thus the activation energy for the second reaction is smaller even though an H_2 bond is still broken in the overall process. In general, the greator the energy involved in the bond formed, the more the activation energy is lowered. An analogous possibility for enzyme catalysis is that side-chain interactions such as H bonds, hydrophobic bonds, etc., are involved in the formation of 'compensating bonds'. A schematic representation of this idea is shown in Fig. 1. Such effects could involve co-operative phenomena so that protein groups not directly at the active site could promote catalysis. Of course, we must ultimately pay for this by breaking the side-chain bonds to get the catalyst back in its original state. However, such processes have small activation energies so that overall the activation energy of the reaction would be lowered. For example, a hydrogen bond can be broken in about 10^{-9} sec[6], solvation structure can be altered in about this same time[7], and the helix–coil transition in polyglutamic acid occurs in less than 10^{-5} sec[8]. Another more obvious example of this type of compensation occurs when part of the substrate molecule forms a covalent intermediate with the enzyme (for example, chymotrypsin[9], phosphoglucomutase[10], etc.).

Table 1. Examples of Energy Compensation in Elementary Gas Phase Reactions*

Reaction	Bond broken	E_a(kcal/mole)
$H_2 \rightarrow 2H$	H–H	104·0
$H_2 + I_2 \rightarrow 2HI$	H–H	40·7
$H_2 + Cl \rightarrow HCl + H$	H–H	4·6–6·1
$H_2 + Br \rightarrow HBr + H$	H–H	17·6
$Cl_2 \rightarrow 2Cl$	Cl–Cl	58·0
$H + Cl_2 \rightarrow HCl + Cl$	Cl–Cl	2·4
$Br_2 \rightarrow 2Br$	Br–Br	92·0
$H + Br_2 \rightarrow HBr + Br$	Br–Br	0·9
$CH_4 \rightarrow CH_3 + H$	C–H	102·6
$CH_3 + C_2H_6 \rightarrow CH_4 + C_2H_5$	C–H	10·4
$H + C_2H_6 \rightarrow C_2H_5 + H_2$	C–H	6·4

* Compiled from ref. 5.

One of the most commonly accepted ideas concerning the role of the enzyme in catalysis is that it rigidly holds the substrates in place so that proton or electron transfer can occur readily. This is undoubtedly at least partially true and may be predominantly an entropic effect. How-

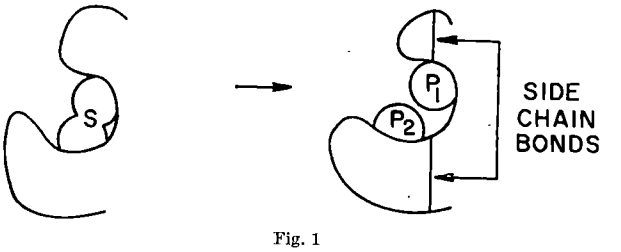

Fig. 1

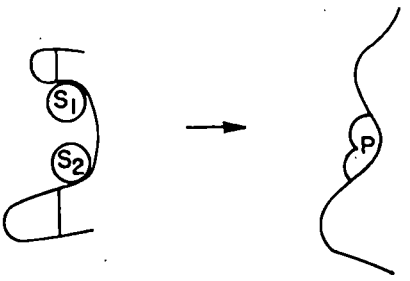

Fig. 2

over, an important consideration is that under ordinary conditions, substrates are very poor proton and electron acceptors and donors; therefore one of the functions of the enzyme may be to polarize the substrate bonds in a manner to facilitate the reaction. This process would involve short-range forces so that positioning would be very critical and might help to explain partially the stereospecificity of enzyme reactions. Possible short-range interactions are ion-induced dipole, ion–dipole, dipole–dipole, etc. As an example of the magnitude of these interactions, consider an ion and an induced dipole where the interaction energy is given by:

$$U(r) = -\frac{\alpha z^2 e^2}{2D^2 r^4}$$

Here α is the polarizability, z is the ionic valence, e is the electronic charge, D is the dielectric constant, and r is the radius of interaction. Taking typical values of α = c.c./mole, $D = 2$ (assuming the protein is the effective media) and $r = 2{\cdot}5$ Å, U is about -5 kcal/mole—a not negligible lowering of the free energy. A related, but by no means identical, idea to this is the previously mentioned 'rack' model where an actual physical strain is exerted on the substrate bonds by the macromolecule[3].

Entropy effects. Entropy effects have been discussed recently by several investigators[11–14]. The basic ideas stressed are the conception of the enzyme as an entropy 'sink'[11], the advantage of putting several catalytic groups together rather than requiring them to come together to form an intermediate complex[12,13] and the advantage of holding the substrate rigidly in place so that the entropy of activation is more favourable in the catalytic steps[14]. Of course, in the latter case the standard entropy of formation of the intermediate is quite unfavourable although the overall effect is probably still to promote the catalysis. The idea of compensating activation entropies may be of importance. A schematic representation of this analogous to the energy compensation previously discussed is shown in Fig. 2. Unfortunately, no good examples of this type of compensation in model systems can be cited. A comparison of entropies of activation for reactions of different molecularity or order is handicapped by the fact that the choice of standard state is completely arbitrary and yet can profoundly affect the numerical results.

Although a detailed interpretation of thermal data for enzyme reactions obtained from steady-state kinetics is not possible, present results suggest that the entropy of formation of enzyme-substrate complexes is often more positive than expected on the basis of simple hydration and electrostatic considerations. Moreover, measurements of volumes of activation suggest that the enzyme structure is loosened when the enzyme-substrate complex is formed[15]. Some experimental results taken from the review of Laidler[15] are given in Table 2. The Michaelis constant in these cases is assumed to be a simple equilibrium constant. This is certainly not correct, but hopefully the results are at least of qualitative significance. The suggestion that 'compensation effects' may be of importance in entropic considerations is certainly consistent with these findings. The nature of the data, coupled with the large spread, of observed values, however, precludes drawing any general conclusions. More recently a kinetic and equilibrium investigation of enzyme-product binding has been carried out with ribonuclease utilizing relaxation methods[16]. These results are also included in Table 2 and again suggest that some sort of entropic 'compensation' occurs.

Table 2. THERMODYNAMIC PARAMETERS OF ENZYME SUBSTRATE COMPLEX FORMATION

Enzyme	Substrate	*p*H	ΔH^0 (kcal)	ΔS^0 (E.U.)
* Chymotrypsin	Methyl hydrocinnamate	7·8	−5·3	−11·3
* Myosin	ATP	7·0	8·0	49·0
* Urease	Urea	7·1	−2·9	0·9
† Ribonuclease	Cytidine-3′-phosphate	‡	> 12·0	> 64·0

*Ref. 15.
† Ref. 16.
‡, *p*H independent.

Conclusions. Many of the foregoing ideas have been put forth previously, but the idea of compensation of activation parameters in the sense discussed here has not been previously stated explicitly to our knowledge. Although this requires that the protein conformation changes continuously throughout the course of the reaction, this is by no means identical with the 'induced fit' theory (although it is certainly not inconsistent with it). Unfortunately, until experiments become more refined, the precise dynamic role of the protein molecule in enzyme catalysis must remain a matter of speculation.

GENESIS AND BIOGENESIS OF ETHYLENE

By DR. MORRIS LIEBERMAN and DR. L. W. MAPSON

Pioneering Research Laboratory for Post-Harvest Physiology, Plant Industry Station, Beltsville, Maryland, and Low Temperature Research Station, Cambridge, England

IN a previous report[1] we showed that ethane could be produced in a particulate system from apples. The components of the system were linolenic acid, thiomalic acid or any acid with an SH on the α-carbon, and cytoplasmic particles in an acetate buffer of *p*H 4·5. We suggested that a relationship may exist between this system and that which produces ethylene in cells. Ethane production in a non-enzymatic system, in which the

Table 1. Ethylene and Ethane Production by a Non-enzymatic Model System in the Presence of Copper or Iron, Reducing Agent, and 'Activated' Linolenic Acid

System*	μl. ethane per 30 min at 30° C	μl. ethylene per 30 min at 30° C
Cupric-ascorbic	1·4	16·0
Ferric-ascorbic	8·0	0·4
Cupric-thiomalic	0·05	0·3
Ferric-thiomalic	7·2	0·2
Cupric-hydroquinone	0·03	0·9
Cupric-hydroxylamine	0·06	0·6

* Flask content: 18 mg of activated linolenic acid; 5 μmole of copper sulphate or ferric citrate; 50 μmoles of reducing agent–ascorbic acid, thiomalic acid, hydroquinone or hydroxylamine hydrochloride; 400 μmoles acetate buffer *p*H 4·5 in a total volume of 5 ml. This mixture was incubated with shaking at 30° C for 30 min in the dark. Linolenic acid was activated by exposure to light at room temperatures for 9 days. Ethylene and ethane were determined by gas chromatography using a 2-ft. by ¼-in. diameter glass column packed with alumina. The detection system was as previously described[4]. The reaction mixture was incubated in 25-ml. stoppered flasks containing a capillary tube clamped with rubber tubing. Gas samplings were made with gas-tight syringes connected to the rubber tubing.

Table 2. Production of Ethylene and Ethane in Cuprous or Cupric Model System in the Absence of a Reducing Agent

System*	μl. ethane per 30 min at 30° C	μl. ethylene per 30 min at 30° C
'Activated' linolenic acid + cuprous ion + acetate buffer *p*H 4·5	0·4	4·2
'Activated' linolenic acid + cupric ion + acetate buffer *p*H 4·5	0·01	0·2

* Flask content: 18 mg active linolenic acid; 5 μmoles of cuprous chloride, dissolved in deoxygenated saturated potassium chloride; or 5 μmoles copper sulphate, and 400 μmoles of acetate buffer, *p*H 4·5. Total volume of liquid in flasks was 5 ml. Linolenic acid was activated by exposure to light at room temperature for 9 days.

Table 3. Effect of 'Activation' of Linolenic Acid on Ethylene Production in the Copper–Ascorbic Acid Model System

System*	μl. ethane per 30 min at 30° C	μl. ethylene per 30 min at 30° C
'Fresh' linolenate + copper + ascorbate + acetate buffer *p*H 4·5	0·02	0·02
'Activated' linolenate + copper + ascorbate + acetate buffer *p*H 4·5	1·1	16·7

* 18 mg of methyl linolenate, 5 μmoles copper sulphate, 50 μmoles ascorbic acid, 400 μmoles acetate buffer in 5 ml. total liquid. Fresh linolenate was obtained from a vial recently opened and stored in nitrogen at −20° C. It showed very little triene conjugation and gave no Kries test. 'Activated' linolenic had been exposed to light and stored in air at room temperature (*c.* 20° C) for approximately 2 weeks. This sample showed a very marked spectrum for triene conjugation and gave a strong Kries test. Methyl linolenate (99 per cent + pure) was obtained from the Hormel Institute, Austin, Minn.

reaction of linolenate and an α-SH acid was catalysed by iron, has also been reported[2]. This article describes an analogous non-enzymatic system which produces predominantly ethylene, rather than ethane. This system differs from its predecessor in two respects: it requires copper rather than iron as a catalyst, and ascorbic acid, rather than thiomalic, serves as the reducing agent for the metal.

Activation of linolenic acid is a critical preliminary requirement for operation of the non-enzymatic model systems, producing either ethylene or ethane. Activation involves conjugation of the three double bonds, followed by some degree of oxidation. The extent of activation was evaluated by: (1) increase in the absorption spectra of the triene conjugated system; (2) by the Kries test for peroxidation[3]; (3) by the oxirane test[3]. These estimates of activation correlated well with ethylene production in the reaction.

Three different procedures were used to activate the fatty acid. In the first, linolenic acid was activated by exposure to air, visible light, and room temperatures (20°–25° C), for a minimum of 3 days. Longer exposures, up to 3–6 weeks, increased the activation. Secondly, exposure to short-wave ultra-violet light (mean wavelength 253 mμ) for 24–48 h, also served to activate the unsaturated fatty acid. Lastly, linolenic acid was activated by a 30- to 60-min incubation in phosphate buffer at *p*H 7·0 with the enzyme lipoxidase.

When activated linolenic acid, or its methyl ester, was incubated with ascorbic acid and copper in acetate buffer at *p*H 4·5, sizable amounts of ethylene and much lower quantities of ethane were produced (Tables 1 and 3). The ratio of ethylene to ethane evolved in this system ranged from about 11 to 15. The same reaction, carried out with ferric ion substituted for cupric ion, yielded a preponderance of ethane.

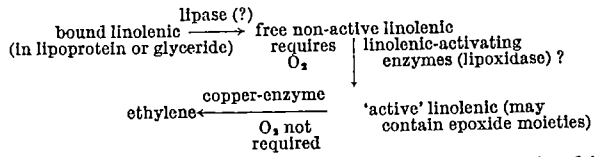
Production of ethylene in the copper system was mediated by the reduced form of the cation (Table 2). The function of ascorbic acid is to produce a steady supply of cuprous ions which interact with activated linolenic acid. Other reducing agents, such as thiomalic acid, hydroquinone, and hydroxylamine, when substituted for ascorbic acid, also gave rise to ethylene in the copper system, by virtue of their ability to reduce cupric ions. However, they are considerably less efficient than ascorbic acid (Table 1). Thiomalic acid was relatively ineffective, due undoubtedly to direct reaction of SH with the cupric ion, which, in effect, sequestered the copper. Other metal cations that exist in two oxidative states, such as manganous, stannous, and cobaltous, could not be substituted for cuprous ion in this reaction. Since the reaction producing ethylene can be catalysed by cuprous ion in the absence of ascorbate (Table 2) the ethylene carbons must derive from linolenic acid.

We have also found that ethylene can be formed non-enzymatically from compounds other than linolenic acid. These appear to have in common either an epoxy or ethoxy group in their molecules. Thus, ethylene oxide, diethyl ether, ethanol, and alkyl phenoxy poly-ethoxy ethanol ('Triton *X*-100'), substituted for activated linolenic acid in the copper–ascorbate system, all give rise to ethylene. There is, however, one distinction between epoxy and ethoxy compounds. Ethylene oxide can form ethylene either in oxygen or in its absence; other epoxy compounds, for example, propylene oxide or 1,2-epoxy butane, form only the corresponding propylene or 1,2-butylene in nitrogen, but do form ethylene in oxygen. Ethoxy compounds produce ethylene only in oxygen atmospheres. We believe the ethoxy compounds may give rise to epoxy compounds, as intermediates, and this step requires the presence of oxygen.

Cytoplasmic particles from apples, prepared as previously described[4], also evolve ethylene in the presence of copper and ascorbate. Linolenic acid is known to be present in apple particles. However, ethylene production from particles is very low when compared to ethylene production by intact fruit. The low activity of the particles might be explained by inactivation of either the enzymatic system responsible for activating linolenic acid, or a copper enzyme concerned in catalysing the final reaction with activated linolenic acid. Alternatively, homogenization of the tissue might cause both the release and acceleration of competing reactions, which can more favourably utilize linolenic acid. Investigations to clarify these points are in progress.

The importance of the model system as a guide to the biosynthetic pathway for ethylene production will, of course, depend on whether it is actually analogous to the natural system. We have made some observations on tissue slices and cytoplasmic particles, which appear to relate the two systems as follows:

(1) Ethylene production by apple plugs is severely inhibited by 10^{-4} M diethyl dithiocarbamate, but not by ethylenediamine tetraacetic acid. These findings suggest that a copper protein is involved since many copper proteins behave in this way[5].



(2) Cytoplasmic particles, with copper and ascorbic acid, will not evolve ethylene in a nitrogen atmosphere, but will produce ethylene in air. Inhibition of ethylene production by nitrogen is characteristic of intact fruit and tissue slices[6].

(3) Cytoplasmic particles from apples can activate linolenic acid for reaction in the copper–ascorbic system. This activation is heat labile and does not proceed in nitrogen.

(4) Ethylene oxide, an inhibitor of ethylene production by intact fruit and occasionally a transient stimulator of ethylene production[4], very readily gives rise to ethylene,

in a nitrogen or oxygen atmosphere in the model system. In the enzymatic system, a specific substrate structure must be required, and linolenic acid with epoxide moieties may provide this requirement. Ethylene oxide, under these conditions, may act as a competitive inhibitor in the enzymatic system by reason of its related structure. In the non-enzymatic system where structural specificity associated with the large fatty acid chain is not involved, the related epoxide moiety can act as substrate for the reaction.

All these factors link the linolenic–copper–ascorbic model system to the natural system for ethylene biosynthesis. Since the components of the model system are known to be present in fruit tissues, a hypothetical scheme may be proposed for the biosynthesis of ethylene, as follows:

Little is known, at present, about the first step in this reaction scheme; but this step may be concerned with freeing bound linolenic acid. After release of the unsaturated fatty acid, various enzymes may compete for linolenic acid, leading to different pathways for its metabolism. The enzymes steering towards the ethylene pathway may activate, by causing triene conjugation followed by peroxidation, in serial steps, which finally lead to the epoxide form. Formation of the epoxide requires oxygen and might be related to the oxygen requirement for ethylene evolution by intact fruit. Lipoxidase might be one of the enzymes involved in this sequence. Once linolenic acid is activated, it can be catalysed very rapidly by the cuprous ion in a copper enzyme. This would then be analogous to the ethylene-producing reaction which proceeds very rapidly, in the model system, with copper, ascorbic acid, and activated linolenic acid, in acetate buffer *p*H 4·5.

Variations of this model system, to be described elsewhere, give rise to saturated hydrocarbons. These reactions require a less-activated (less-oxidized) form of linolenic acid, and can proceed in a nitrogen atmosphere. The genesis of petroleum and hydrocarbon gases from lipids of prehistoric living forms, buried underground, may have arisen anaerobically, via similar reaction pathways.

This work was supported by grant *GB*–1094 from the U.S. National Science Foundation.

Addendum. Since completion of the experiments described we have found that methionine, but no other amino-acid, can also react in the copper–ascorbate system to form significant amounts of ethylene. Unlike the linolenate system, the methionine system produces no ethane and does not form ethylene in nitrogen. This is reminiscent of the natural ethylene system in apple and other fruit. Furthermore, methionine is unique, among the substances which form ethylene in the copper–ascorbate model system, in its ability to stimulate ethylene production in apple tissue slices.

An analysis of the particulate fraction isolated from apples shows that at least two compounds are present which can give rise to ethylene with the copper–ascorbate system. The first is associated with the fat-soluble and the second with the water-soluble constituents of the cell. It therefore appears that there may be more than one ethylene-forming precursor in tissues.

HISTOLOGICAL REACTIONS OF *Bufo melanostictus* TO CULTURE FILTRATES AND MYCELIAL EXTRACTS OF A PATHOGENIC FUNGUS

By Dr. S. S. DHALIWAL and Dr. D. A. GRIFFITHS
University of Malaya, Kuala Lumpur, Malaysia

It was previously reported[1] that naturally occurring infection of Malayan toads (*Bufo melanostictus*) by an unidentified fungus produced ulcerated skin lesions and tumour-like nodules on the skin, abdominal wall and internal organs. Pure cultures of the fungus, isolated from diseased toads, when inoculated into healthy toads induced the same histological reactions, that is, nodular formations on the abdominal wall and internal organs consisting of accumulations of monocytes surrounding a central locus of fungal hypha. Attempts were then made to induce similar histological reactions using mycelial extracts and cell-free culture filtrates of the causal organism.

The fungus was grown in 250 ml. aliquots in liquid culture medium consisting of 2·5 per cent glucose, 0·1 per cent yeast extract, 0·2 per cent peptone and mineral salt at *p*H 6·3 and incubated in the dark at 27·5° C. (*a*) The fungus was filtered off through Whatman No. 52 filter paper and the resultant 4 l. of culture filtrate were concentrated under vacuum at 60° C on a 'Rotavapor' to approximately 50 ml. The concentrate was dialysed against running tap-water for 12 h, reconcentrated under vacuum and centrifuged at 3,000 r.p.m. for 10 min and the supernatant filtered through a bacterial membrane filter ('Membran' filter) under vacuum. (*b*) The mycelial mats collected from (*a*) above were alternately frozen for 3 h at −20° C and thawed at 40° C four times and the resultant slurry further disrupted by means of a sonic disintegrator (Branson sonifier U.S. model *L.S.* 75) at frequency 8 for 6 periods of 1 min each alternating with 15-min periods at 0° C. The slurry was centrifuged at 6,000 r.p.m. for 10 min and the supernatant dialysed against distilled water at 0° C for 6 h. Half the dialysate was kept at 60° C for 15 min (solution *b*1), and this together with the non-heated dialysate (solution *b*2) were passed through a bacterial filter and tested against healthy toads.

Spent fungal medium. 1 ml. aliquots of the solution obtained from (*a*) were introduced by means of a sterile hypodermic needle into the subcutaneous cavity and abdominal walls, in the lower abdominal region of healthy toads. Control toads wounded by sterile needles were also established, and these together with the inoculated toads were kept in large aquaria and samples removed for dissection after 8-, 10-, 12- and 14-day intervals. After 8 days, inoculated toads showed marked inflam-

matory reactions 1–2 mm in diameter at the site of skin and abdominal puncture together with zones of inflammation at the xiphisternum. This reaction was in marked contrast to the control toads, where no apparent reaction was seen. Tissue immediately surrounding sites of skin and abdominal puncture was removed, fixed in Bouin's solution, sectioned and stained either with eosin/hæmatoxylin or in Schiff's reagent following pre-treatment with periodic acid. Sections showed that immediately surrounding the site of skin puncture monocytes had accumulated in the poison glands and the dermal layers, while the epidermis had become multiseriate with consequent gross invagination of the tissue. The main migration of the inflammatory cells appeared along channels of connective tissue extending from the subcutaneous cavity through the muscle layer (Fig. 1), suggesting that the initial inflammatory reaction occurred on the inner surface of the skin following subcutaneous injection. Sections at the site of abdominal puncture showed initially an accumulation of monocytes followed by the development of a large mass of inflammatory tissue within the abdominal wall. Thickening of the abdominal wall in this region was brought about by the migration of monocytes in the connective tissue surrounding the myocommata (Fig. 2). At the xiphisternum monocytes accumulated within the thin envelope of connective tissue covering the ventral surface of the cartilage and later within tissues on the dorsal surface. Reactions at this region suggest that the culture filtrate introduced into the subcutaneous cavity in the lower abdomen had migrated along channels in the connective tissue between the skin and abdominal wall.

Mycelial extract. 1 ml. aliquots of the solution obtained from (*b*) here were introduced into the subcutaneous cavity and the abdominal walls of healthy toads. Inflammatory reactions similar to those described here were examined and proved to be histologically identical. One feature of interest was the marked increase in thickness of the epidermal layer 3–4 days after inoculation, that is, before the appearance of any marked inflammatory reaction. In order to examine this phenomenon in more detail 0·2 ml. aliquots of the mycelial extract were placed on the dorsal surface of healthy toads and the skin immediately beneath the drop was scarified by means of a sterile scalpel. After scarification another 0·2 ml. of extract was placed on the scar and the toads were placed in a dry portion of the aquarium to avoid excessive dilution of the extract. Another series of animals were inoculated in a similar way with mycelial extract that had been kept at 60° C for 15 min. Control toads scarified by means of a sterile scalpel were also maintained. Three days after inoculation animals bearing untreated extract exhibited, at the site of scarification, an inflammatory reaction which enlarged during the next 5 days to form an ulcerated zone 1·5–2 cm in diameter. Portions of the skin and abdominal wall at the site of inoculation were removed at daily intervals and examined for histological features. During the first 4 days after inoculation monocytes accumulated in the poison glands, where they divided mitotically (Fig. 3) and passed out along the neck of the gland to lie immediately beneath the epidermal cells.

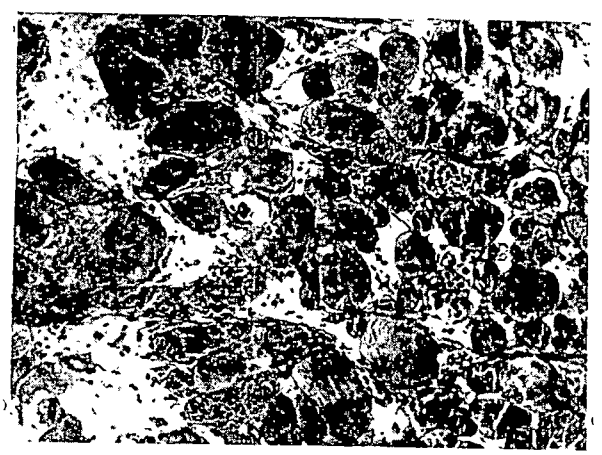

Fig. 2. Monocytes in connective tissue within the abdominal wall

Fig. 3. Mitotic division of monocytes (arrowed) in poison gland. Note the thickened epidermis

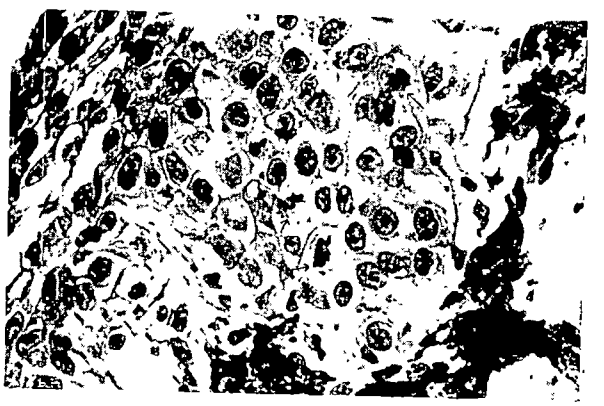

Fig. 4. Divisions in the multiseriate epidermis. (Cells in mitosis arrowed)

Fig. 5. Early stage in division in the epidermal layer

Later rapid divisions within the epidermal tissue (Fig. 4) resulted in a gross thickening of the epidermal layers. During the period of division, that is, the first 5 days after inoculation a mitotic index ranging from 2 to 7/100 cells was frequently observed. In some instances mitotic divisions were induced in the uniseriate epidermal layer (Fig. 5) before migration of monocytes from the poison glands had occurred. Within the abdominal wall monocytes migrated from the blood capillaries into the connective tissue between the myocommata, where rapid mitotic division occurred (Fig. 6). Toads bearing heated mycelial extract, together with toads which had been scarified by means of a sterile scalpel, showed no inflammatory reactions and sections failed to reveal mitotic divisions within any of the tissues.

From these observations it is concluded that the unidentified fungus causing acute lethal inflammatory reactions in toads produces an extramycelial thermostable factor capable of inducing histological reactions

Fig. 6. Mitotic divisions (arrowed) in inflammatory cells within the connective tissue of the abdominal wall

similar to those resulting from fungal invasion, while water extracts of the mycelium contain a thermolabile substance capable of inducing cellular proliferation both in the epidermis and in migrating monocytes within the connective tissues of the abdominal wall. Present work is directed at the establishment of a culture medium from which the factors involved may be isolated together with a biological assay method for determining the relative potency of the substance during extended trials.

COLLAGEN AND CELL PROTEIN SYNTHESIS BY AN ESTABLISHED MAMMALIAN FIBROBLAST LINE

By Prof. HOWARD GREEN and Prof. BURTON GOLDBERG

Department of Pathology, New York University School of Medicine

We have recently reported that cells of an established mouse fibroblast line (3*T*6) secrete collagen in culture, the collagen precipitating as typical fibres between the cells[1]. Examination of the relation of cell growth to accumulation of collagen in the cell layer showed that collagen appeared after the phase of exponential growth was completed, and accumulated at a constant rate for at least three weeks thereafter[2]. This communication describes experiments on the relation of cell protein synthesis to collagen protein synthesis under different conditions, with the view of determining the factors controlling this differentiated function of the fibroblast.

All cultures were grown in plastic Petri dishes, in the Dulbecco–Vogt modification of Eagle's medium[3]. The medium of all cultures was changed three times weekly. Three replicate cultures of 3*T*6 were allowed to grow to saturation density. At time zero (Fig. 1), one culture was trypsinized and 16 daughter cultures inoculated at about 1/70th of the cell density of the parent culture. Daughter cultures were trypsinized at intervals during the next 10 days and the cells counted. Fig. 1*A* shows the resulting growth curve. At various times, uniformly labelled L-proline-^{14}C was added in fresh medium to one of the daughter or parent cultures. After 12 h incubation with the isotope, activity was stopped with trichloroacetic acid. The contents of the cultures (cells plus medium) were exhaustively dialysed, first against unlabelled proline and hydroxyproline, then against several changes of dilute phosphate buffered-sodium chloride solution. The non-dialysable portion was then hydrolysed in 6 N hydrochloric acid at 120° for 12 h, a known amount of carrier proline and hydroxyproline added and these two amino-acids re-isolated by thin-layer chromatography, according to the method of Myhill and Jackson[4]. Their isotope content was determined and the total radioactivity incorporated into protein as proline and as hydroxyproline was calculated for each culture. Assuming that the pool of free cell proline serves as precursor of the hydroxyproline residues of collagen and of the proline residues of all proteins, that hydroxyproline is incorporated only into collagen, and knowing the abundance of hydroxyproline in collagen and of proline in the cell protein, the ratio of collagen synthesis to cell protein synthesis can be calculated (Fig. 1*B*). This ratio can be regarded as an index of differentiation of the fibroblast. The data show that in saturation density cultures 3–3·5 per cent of the protein synthesized is collagen (curve 1, Fig. 1*B*). The daughter cultures do not lose differentiated function immediately; the amount of collagen synthesis relative to cell protein synthesis begins to drop

after inoculation (curve 2) but does not reach the lowest value until after two days, by which time considerable cell multiplication has occurred. At this time about 0·25 per cent of the protein being made is collagen. As the daughter cultures approach saturation density the rate of collagen synthesis relative to cell protein synthesis begins to rise rapidly and soon approaches the values typical of saturation density cultures.

The *p*H of the culture medium, normally 7·2, is not detectably reduced two days after its addition so long as the cell population is lower than 2×10^6 per plate, but at higher cell densities the *p*H drops appreciably between medium changes. In saturation density cultures (10^7 cells) most of the glucose initially present in the medium (4·5 mg/ml.) is converted to lactic acid[6] and the *p*H drops to 6·6. In order to determine if these changes in the medium of saturation density cultures influence collagen production, the effect of addition of lactic acid was investigated in cultures containing less than 2 million cells.

To replicate cultures containing about 10^5 cells each, lactic acid was added in varying concentrations. Thirty-six hours later the medium of each was replaced with fresh medium of the same lactic acid concentration, containing labelled proline. Twelve hours later, cold trichloroacetic acid was added and the products treated in the usual manner. In Fig. 2*A* the total radioactivity incorporated into the proline and hydroxyproline residues of the protein is shown. The addition of lactic acid was

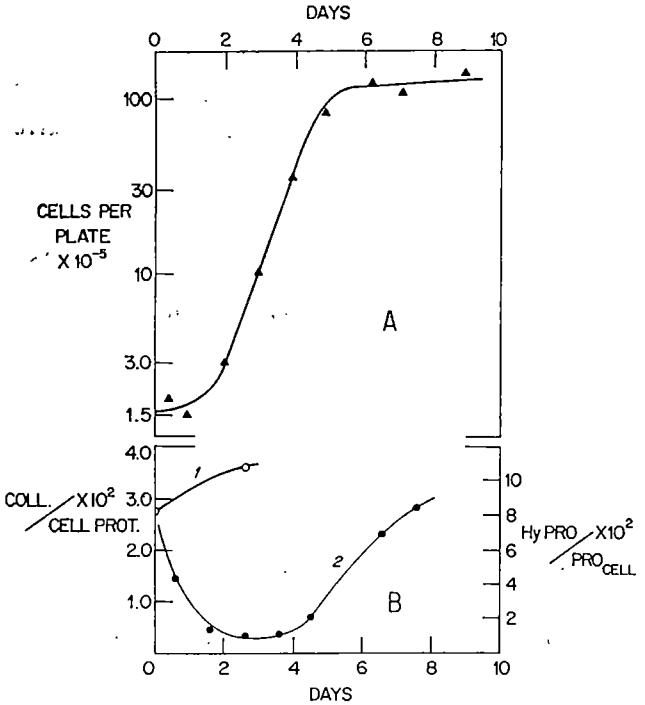

Fig. 1. Synthesis of collagen during growth of 3*T*6. *A*, Growth curve of 3*T*6 following trypsinization of a saturation density culture and inoculation of the daughter cultures at time 0; *B*, Protein synthesis by replicate cultures. Right-hand ordinate gives ratio of counts incorporated into collagen hydroxyproline to that incorporated into proline of 'cell' protein. Left-hand ordinate gives ratio of collagen synthesized to cell protein synthesized. Curve 1, parent cultures allowed to remain at saturation density. Curve 2, daughter cultures the growth of which is shown in *A*

Calculations: (1) It is assumed that all counts incorporated into non-dialysable hydroxyproline (HyPRO) represent collagen synthesis. (2) Proline incorporation is mostly into non-collagen ('cell') protein, but also to a small degree into collagen. Since collagen contains 1·2 proline residues for each hydroxyproline residue[5], 1·2 × HyPRO counts must be subtracted from the total proline counts to give non-collagen protein-incorporated proline (designated PRO_{cell}). This correction is negligible for all but the highest HyPRO values. (3) Since the HyPRO residue content of collagen is 12·2 per cent, while the PRO residue content of cell protein is 4·1 per cent (determined directly on cell hydrolysates by column chromatography), the value $HyPRO/PRO_{cell}$ is multiplied by 4·1/12·2 to give the ratio of collagen synthesis to cell protein synthesis (Coll./Cell Prot.)

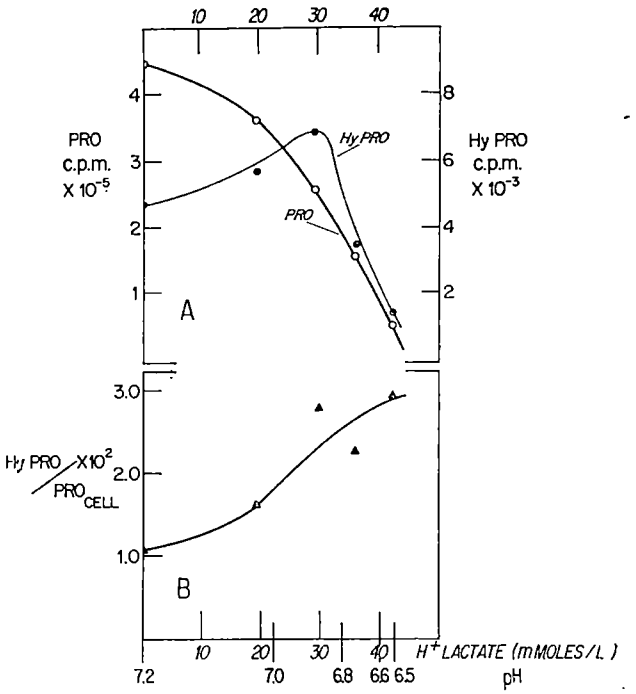

Fig. 2. Effect of added lactic acid on incorporation of proline and hydroxyproline into protein (see legend to Fig. 1)

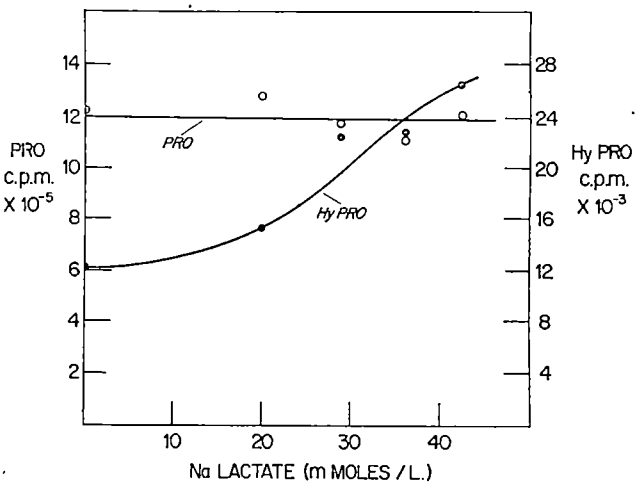

Fig. 3. Effect of added sodium lactate on incorporation of proline and hydroxyproline into protein

inhibitory to cell protein synthesis, as judged by proline incorporation, beginning at the lowest concentration tested, and became much more inhibitory at higher concentrations. Even at the highest concentration tested (43 mM) appreciable growth occurred in the cultures during the first 36 h (nearly 2 cell generations), but by 48 h mitoses were completely absent from the culture. Cultures incubated in the absence of added lactic acid grew slightly over three generations during the 48 h.

The effect of lactic acid on collagen synthesis followed a pattern different from that on cell protein synthesis. In the presence of low concentrations of lactic acid there was an increase in hydroxyproline incorporation, and only at the highest concentrations of lactic acid did the synthesis of collagen decline along with that of the other proteins. The ratio of hydroxyproline incorporation to proline incorporation, plotted in Fig. 2*B*, rose at the higher lactic acid concentrations to about three times that in its absence.

In order to decide which of these effects were produced by hydrogen ion and which by lactate ion, the experiment

was repeated, using sodium lactate instead of free lactic acid, so that the *p*H of the medium was unchanged at all lactate concentrations. Fig. 3 shows the result obtained. Cell protein synthesis, as judged by proline incorporation, was completely unaffected up to the highest concentration tested. This is consistent with the fact that even the highest lactate concentration did not affect the growth-rate of the cells. Collagen synthesis, on the other hand, was stimulated in a manner quite similar to that observed on the addition of lactic acid. It may be concluded that the inhibition of cell protein synthesis following the addition of lactic acid is due to hydrogen ion, while the stimulation of collagen synthesis is due to lactate ion.

These effects are consistent with the changes in collagen synthesis found in cells passing from exponential growth to the stationary phase. However, the magnitude of the lactate effect (2–3 times increase in the fraction of cell protein made which is collagen) is much smaller than the difference observed between exponentially growing and saturation density cultures (up to 15-fold). It may be that the lactic acid produced is only a minor factor influencing the state of differentiation of fibroblast cultures, or that the conditions obtained by adding lactic acid to exponentially growing cultures do not duplicate the lactic acid concentrations existing within the cell layers of saturation density cultures.

These experiments show that the metabolic products of a cell can control, within a range, the expression of its capacity for differentiated function. The level at which this effect is exerted (gene, ribosome, etc.) remains to be determined.

TUMOUR SPECIFIC IMMUNITY AGAINST MURINE EPITHELIOMAS INDUCED WITH 9,10-DIMETHYL-1,2-BENZANTHRACENE

By Mrs. M. A. TUFFREY and Dr. J. R. BATCHELOR

Department of Pathology, Guy's Hospital Medical School, London, S.E.1

THE presence of tumour-specific antigens in certain chemically induced mouse tumours is now well established[1–5]. There are less data on rat tumours[6–9], but such as there are indicate that these may also possess tumour-specific antigens. The significance of such antigens is naturally of great interest, and for this reason it is important to learn how widespread is the phenomenon of specific antigenicity. The earliest work was performed on murine fibrosarcomas induced with 3-methylcholanthrene. Since then, specific antigens have been demonstrated in tumours provoked by a number of polycyclic hydrocarbons, including 1,2,5,6-dibenzanthracene[10], 3,4,9,-10-dibenzpyrene[5], 3,4-benzpyrene[5], and *p*-dimethylamino-azobenzene (cited in ref. 11). In most series, the tumours tested for specific antigenicity were fibrosarcomas. However, there is evidence that chemically induced mouse breast tumours[12] and hepatomas (cited in ref. 11) possess tumour-specific antigenicity. In the experiments described here, we have examined epitheliomas induced in *C57BL* mice with 9,10-dimethyl-1,2-benzanthracene. Evidence of tumour-specific antigenicity has been obtained in four out of five epitheliomas investigated. In addition, attempts to demonstrate antibody against such antigens have been made.

C57BL or *BALB/c* × *C57BL* hosts were given a preliminary course of immunization. For immunization, either lyophilized tumour or heavily irradiated tumour brei was used. Tumour breis were irradiated by a cobalt-60 source, 15,000 r. being given at a rate of 1,000 r./15 sec. Three injections were given over 6 weeks, each mouse receiving between 25 and 75 mg either of lyophilized tissue or irradiated tumour. In two experiments adoptive immunization was performed using spleen cells from syngeneic tumour-bearing mice. After immunization, the recipients were challenged with increasing numbers of normal tumour cells capable of replication, and growth was compared with that occurring in controls. In many experiments, delay in growth rather than complete inhibition of the tumours was observed, and in these cases the tumours were excised and the mice re-challenged at a later date with a higher tumour dose. Controls were either non-immune mice of the same genotype, or, in about half the experiments, they were 'immunized' with irradiated syngeneic normal tissue. It should be mentioned that histogenetic homogeneity of all strains in our colony is routinely confirmed at least once annually by intra-strain skin grafts made between several offspring of different breeding pairs. Tumour challenge was performed with trypsinized cell suspensions prepared according to Boyse's method[13]. It was necessary to use both *C57BL* and *BALB/c* × *C57BL* hosts due to limited mouse supplies. There is evidence that parental strain parental strain[14,15]. The reason for this is unknown, but tumours grow more slowly in F_1 hosts than in the native we felt that the slower growth of the tumour in F_1 hosts might allow greater opportunities for the recipients to become immunized before being overwhelmed by tumour growth.

However, there is one complication in the use of F_1 hosts. Bailey[16] has recently described an *X* chromosome-linked histocompatibility system. He showed that if paternal strain male skin is transplanted to F_1 males, rejection may occur. Skin grafts from males of the maternal strain survive indefinitely. This problem applies only to male recipients which have a single *X* chromosome. There is no incompatibility in the F_1 females grafted with paternal strain female tissues, as in this case recipients have an *X* chromosome from both parent strains. We have performed appropriate skin grafts on our *BALB/c* × *C57BL* hybrids in order to test for the *X* linked histo-compatibility system. Table 1 shows the results.

Because of the results given in Table 1, it is clearly unsatisfactory attempting to demonstrate tumour-specific antigens in a ♂ tumour by immunizing (*BALB/c* × *C57BL*) ♂ hosts. Any results might equally be due to *X* linked iso-antigenic differences. However, no such incompatibility is involved if *C57BL* ♀ tumours are transplanted to (*BALB/c* × *C57BL*) ♀ recipients. We have therefore used only parental strain male hosts when testing for antigenicity of the epitheliomas *Ep.* 3 and 4, which arose in *C57BL* ♂s; the remaining tumours which originated in *C57BL* ♀s, *Ep.* 5, 6, and 8, were tested in (*BALB/c* × *C57BL*) ♀ hosts.

Table 1. Survival of Paternal Strain Skin Grafts on Hybrid Recipients

Donor	Recipients	Results
C57BL ♂	(*BALB/c* × *C57BL*) ♂	Nine out of 11 hosts grafted showed complete rejection between seventh and fourteenth week. Two animals were regrafted and showed second set responses
C57BL ♀	(*BALB/c* × *C57BL*) ♀	Five animals grafted. All healthy at > 30 weeks

When hosts were challenged with suspensions of the same tumour that had been used for pre-immunization, two types of results were observed. Table 2 illustrates the first type, in which immunization conveyed protection on the host. It can be seen that pre-immunization afforded protection in four out of five tumours investigated. As others have done[4,5], we found immunity to be weak and easily overridden.

Table 2. Growth of Dimethyl-benzanthracene-induced *C57BL* Epitheliomas in Immune and Non-immune *C57BL* or (*BALB/c* × *C57BL*) Hosts

* Controls 'immunized' with irradiated normal *C57BL* tissue.
† Experimental mice were adoptively immunized.

However, pre-immunization sometimes had an opposite effect in that it caused increased susceptibility to tumour growth. Table 3 gives details of the experiments in which this was observed.

Table 3. Increased Susceptibility to the Growth of Dimethyl-benzanthracene-induced *C57BL* Epitheliomas in *C57BL* or (*BALB/c* × *C57BL*) Hosts after Pre-immunization

Tumour	Immunization	Challenge dose (cells × 10^3)	Tumour growth (mice with tumours/No. in group) Immune	Non-immune	No. of days between challenge and measurement
Ep. 4	3 injections of irradiated *Ep.* 4 i.p.	6	10/15	1/4	13
Ep. 6	1 injection of normal *Ep.* 6 s.c. No visible tumour ensued	20	5/5	2/6	34
	3 injections of irradiated *Ep.* 6 i.p.	67	7/16	0/5*	28
Ep. 8	3 injections of irradiated *Ep.* 8 i.p., followed by 2 s.c. inocula of normal *Ep.* 8 cells	319	13/15	0/4	40

* Controls pre-immunized with irradiated normal *C57BL* tissue.

The appearance of increased susceptibility to tumour growth followed a variety of immunization schedules. With *Ep.* 6, increased susceptibility was observed in one experiment after a single subcutaneous injection of 5·3 thousand normal tumour cells. However, in most experiments, the schedules were more extensive. The most prolonged schedule was used in the experiment with *Ep.* 8. Here 3 injections of irradiated tumour were followed by 2 subcutaneous inoculations with untreated tumour cells. These doses were insufficient to cause palpable growths except in two recipients, and in these two cases the tumours were excised at an early stage.

The occurrence of increased susceptibility was too erratic for a systematic analysis of the observation to be carried out in these experiments. As yet there are few data to indicate whether it is specific to the tumour used for pre-immunization or not. In only one experiment where increased susceptibility was observed (with *Ep.* 6) did animals of the control group receive a similar schedule of normal tissue. Other workers[4] investigating comparable systems have not observed any non-specific depression of the immune response. It seems unlikely that as little as 5·3 thousand non-irradiated *Ep.* 6 cells, insufficient to produce a visible tumour, were nevertheless capable of inducing a non-specific depression of the host's immune response. However, the possibility does still remain.

If the increased susceptibility is found to be specific to the tumour used for pre-immunization, at least two possibilities must be considered, namely, tolerance and immunological enhancement. It is of interest that the same schedules which induced anti-tumour immunity, in other experiments provoked an increased susceptibility. This is perhaps slightly more suggestive of enhancement than tolerance. Whatever is the explanation of this observation, it is clearly of great practical importance if attempts to immunize human cancer patients against their own tumours are undertaken.

Attempts to detect humoral antibody against tumour-specific antigens have been tried by three different methods.

(1) Sera were prepared in *H*-2 incompatible strains by schedules of 3–5 injections of epithelioma tissue. Afterwards, the sera were tested by passive immunization[15,17,18]. *C57BL* hosts were inoculated intraperitoneally with antiserum, and approximately 2 h later challenged subcutaneously with known numbers of the same epithelioma used in the immunization schedule. Tumour growth was compared with that occurring in control mice which had received tumour only. In this type of experiment, the assumption is made that antibodies against normal tissue antigens are absorbed within 2 h. Antibodies reacting with tumour-specific antigens would, of course, not be absorbed, and hence be free to influence the growth of the tumour later inoculated. Despite doses of 0·5 ml. per mouse of antiserum, there were no significant differences in tumour growth between serum-treated mice and controls.

Sera were also collected from the immunized *C57BL* and *BALB/c* × *C57BL* hosts described earlier. The activity of these sera was tested in two ways.

(2) Cytotoxic tests were performed according to the method of Gorer and O'Gorman[19]. However, none of the sera showed any cytotoxic activity.

(3) Neutralization tests[20,21] were carried out in which aliquots of tumour suspension were incubated *in vitro* either with test antiserum or with a control non-reacting serum. After incubation for 45–60 min at 37°, the cell–serum mixture is inoculated into *C57BL* or *BALB/c* × *C57BL* hosts, and the subsequent tumour growths observed. For maximum sensitivity in this type of experiment, threshold doses of tumour cells should be used. We were unable to detect any differences between control and experimental groups despite the use of threshold inocula of tumour cells, except in two experiments in which very large doses of serum were used. The details of these are given in Table 4. From this Table it can be seen that there was some inhibition of the growth of *Ep.* 3 in mice injected with tumour and anti-*Ep.* 3 serum. In the second experiment in which *Ep.* 6 was used, tumour growth occurred in a larger fraction of the group treated with anti-*Ep.* 6 serum than was seen in the control serum group. Possibly

Table 4. Neutralization Experiments
Tumour cells mixed with serum were incubated at 37° prior to subcutaneous inoculation

Tumour	Serum	Tumour growth: fraction of mice in group with progressive tumours
Ep. 3	0·5 ml. *C57BL* ♂ anti-*Ep.* 3	1/5
42 × 10^3	0·4 ml. *C57BL* ♂ anti-*Ep.* 3	1/3
cells	0·2 ml. *C57BL* ♂ anti-*Ep.* 3	0/4
	0·2 ml. *C57BL* anti-*C3H*	3/5
Ep. 6	0·5 ml. (*BALB/c* × *C57BL*) ♀ anti-*Ep.* 6	4/5
	0·5 ml. (*BALB/c* × *C57BL*) ♀ anti-*Ep.* 6	4/5
	0·2 ml. (*BALB/c* × *C57BL*) anti-*C3H*	2/5

Three different samples of antiserum were used in the first experiment and two were used in the second. *C57BL* ♂ hosts were used in the first experiment, and (*BALB/c* × *C57BL*) ♀s in the second.

this is an example of enhancement. Unfortunately the large amount of serum required has prevented us from repeating these experiments, and their significance is correspondingly in doubt. But it is already clear that the method will not provide a satisfactory basis for biochemical characterization of these antigens.

These results are similar to those obtained with other types of chemically induced tumours. Despite clear evidence of tumour specific immunity, Klein *et al.*[4] were unable to detect humoral antibody activity against methylcholanthrene sarcomas. Old *et al.*[5] describe only one example in their series of dibenzpyrene-induced sarcomas. The general lack of success in demonstrating antibody activity is disappointing, but perhaps only to be expected in view of the extremely weak antigenicity of these tumours. However, if progress in chemical investigations on tumour-specific antigens is to be made, it is essential that reliable *in vitro* detection techniques are developed.

FACTORS AFFECTING THE EXPANSION OF THE STEM CELL POOL IN TRANSPLANTED MOUSE BONE MARROW

By M. BENNETT, G. M. SHEARER, A. C. UPTON and G. CUDKOWICZ

Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

SERIAL transplantation of mouse bone marrow in X-irradiated isogenic recipients may result in progressive loss of the marrow's ability to promote survival and hæmopoietic recovery[1,2], of its capacity to proliferate and produce undifferentiated stem cells and differentiating blood cells (that is, depletion of its stem cell pool)[3,4], and of the marrow 'lymphocytes'[3,4]. Although the magnitude of these effects varies with the number of successive transplantations, the impairment of proliferative capacity has also seemed to depend on the number of marrow cells transplanted. Perhaps the hæmopoietic stem cells can be restricted in number by excessive pressure to differentiate when small numbers are transplanted into heavily irradiated recipients, differentiation occurring at the expense of the proliferation of otherwise self-perpetuating cells.

This investigation was concerned with the effects of experimental modifications thought to decrease or increase the need for the production of differentiated hæmic cells by the transplanted marrow. Specifically, it explored the effects of varying the number of marrow cells transplanted, of hypertransfusing the recipients of the marrow with erythrocytes or lymph node cells, and of grafting marrow from female donors into isoantigenic male recipients.

Femoral marrow cells from adult $(BALB/c \times A/He)F_1$ females were suspended in Tyrode's solution and injected intravenously into adult isogenic female recipients which had been exposed earlier on the same day to 850 r. whole-body X-radiation ($LD_{100/30}$). Each recipient received 5×10^5, 5×10^6, or 5×10^7 nucleated cells. Fifty days after injection, 3 chimeras of each recipient dose group were killed, and the competence of their marrow to proliferate on transplantation was assayed in terms of splenic repopulation in irradiated isogenic female test recipients. The 50-day interval for the assay was chosen because this length of time had been found to be adequate for complete regeneration of the marrow proliferative capacity after transplantation of 10^7 cells, but not of 5×10^5 cells[3,4]. The test recipient mice were exposed to 700 r. of whole-body X-rays and were given a standard dose of 10^6 nucleated chimera marrow cells by tail vein, the marrow of each chimera being infused into 5–10 test mice. Five days later, 0·5 μc. of ^{131}I-labelled 5-iodo-2′-deoxyuridine (^{131}IUdR), a thymidine analogue, was injected intraperitoneally into each test recipient to label the cells synthesizing deoxyribonucleic acid (DNA) in the spleen. Each of the test mice was killed 6–17 h after injection of the ^{131}IUdR, and its spleen assayed for radioactivity by crystal scintillation counting. Under the conditions used, the splenic uptake of the DNA precursor, expressed as a percentage of the total radioactivity originally available for incorporation, was linearly related to the donor marrow cell dose, from $0{\cdot}5 \times 10^5$ to 10×10^5 transplanted nucleated cells[3,4] and was, furthermore, a constant function of the number of 'lymphocytes' but not of other types of cells in the donor marrow[5]. As judged by the ability of transplanted cells to repopulate the spleen of test mice, the marrow of chimeras that had been given 5×10^5 hæmopoietic cells remained subnormal at the time of the assay (Table 1). After infusion of larger numbers of hæmopoietic cells the deficiency in proliferative competence of chimeric marrow was less severe or absent (Table 1). In fact, the proliferative capacity of marrow from chimeras infused with 5×10^7 cells overshot the normal (Table 1) as in an earlier experiment[3]. This overshoot, although small, suggests that the pattern of proliferation of transplanted marrow stem cells may be similar to the pattern of marrow regeneration that follows irradiation alone, as was shown by Alexanian *et al.*[6].

In an effort to lower the intensity of stimuli favouring the differentiation of stem cells into erythropoietic and lymphopoietic elements, we hypertransfused isogenic marrow chimeras with erythrocytes and/or lymph node cells, since polycythæmia suppresses erythropoiesis in marrow and spleen[7] and lymph node cells seed the lymphoid structures on transplantation into irradiated marrow-injected mice[8]. Male $(C3H/Anf \times C57BL)F_1$ mice were used as primary marrow recipients for this phase of the experiments. They were exposed to 950 r. of whole-body X-rays ($LD_{100/30}$) and infused promptly thereafter with 5×10^5 nucleated marrow cells from

isogenic female donors. Red blood cells were gathered from male mice of the same strain, pre-exposed to 1,000 r. of X-rays to inactivate the few circulating stem cells that might be present along with the erythrocytes. The red blood cells were centrifuged from heparinized blood, separated from the buffy coat, and given intraperitoneally to the marrow recipients as an 80 per cent suspension in Tyrode's solution. Transfusions of 0·5–1·0 ml. each were initiated one day before marrow transplantation and continued thereafter for 5 weeks, three times a week during the first two weeks and twice a week later. A second group of chimeras was injected with lymphoid cells obtained from mesenteric nodes of isogenic male donors not pre-exposed to radiation. The cells were suspended in Tyrode's solution and injected into the peritoneal cavity of the chimeras in numbers ranging from $3{\cdot}5 \times 10^6$ to $7{\cdot}4 \times 10^6$ nucleated cells per injection. The treatment was initiated on the day of the marrow transplantation and continued twice weekly for 5 weeks. A third group of chimeras received both erythrocytes and lymph node cells, but on different days. A fourth group of chimeras was injected with Tyrode's solution alone. The proliferative competence of the marrow of each chimera was assayed as described here, except that the $(C3H/Anf \times C57BL)F_1$ female test recipients were exposed to 800 r. of X-rays before inoculation of the chimera marrow cells. The values of the marrow proliferative capacity of 7 chimeras injected with Tyrode's solution and of 20 chimeras transfused with erythrocytes and/or lymph node cells are presented in Table 2. It is evident that all the treatments enhanced the proliferative competence of transplanted marrow as compared with the Tyrode's solution alone. It would appear that administration of lymph node cells was less effective than hypertransfusion of erythrocytes. It may be postulated that the red blood cell transfusions exerted a greater effect because the resulting polycythæmia was sufficiently marked and prolonged to suppress erythropoiesis[7], whereas the persistence of the infused lymphocytes may have been relatively transitory[8], because most of them are not endowed with active reproductive capacity[9]. The failure of the two treatments to show greater effects when combined may conceivably have resulted from demands on the marrow stem cell pool for differentiation into immunologically competent cells, that is, the donor marrow cells were of female origin and may have been stimulated to react immunologically against their male hosts by the presence of male isoantigen (*vide infra*).

In an effort to detect stimuli favouring the differentiation of stem cells into immunologically competent elements, we injected female marrow cells into both female and male recipients. Male mice possess a male-specific isoantigen which elicits an antibody response adequate for rejection of male skin or spleen grafted into isogenic female recipients[10–12]. 5×10^5 nucleated marrow cells from female donor mice were infused into whole-body (950 r.) X-irradiated female and male isogenic $(C3H/Anf \times C57BL)F_1$ recipients. To extend the test, 5×10^5 nucleated marrow cells were retransplanted 35 days later from chimeras of both sexes into a second set of recipients of the same sex. The proliferative capacity of the marrow was evaluated 35 days after each transplantation by injection of 10^6 nucleated chimera cells into irradiated test mice. Reduction of the ability of transplanted marrow to promote incorporation of ^{131}IUdR in the spleens of test recipients occurred to a greater extent in female–male grafts than in female–female grafts (Table 3). In both types of grafts, the deficiency in marrow proliferative capacity was greater on the second than on the first transplantation, in keeping with earlier observations[3,4].

From the foregoing experiments, we infer that mouse marrow cells transplanted into lethally irradiated recipients may be unable to regenerate a normal-sized hæmopoietic stem cell population if the requirements placed on them for differentiated cells are too great in relation to the available supply of transplanted stem cells. However, if large enough numbers of marrow cells are transplanted, or if the recipients are supplied directly with differentiated blood cells during the critical stages of hæmopoietic repopulation, reproduction by donor marrow stem cells may be adequate to restore rapidly the pool of such cells to normal levels. Conversely, if the requirements for production of differentiated blood cells are increased, as is the case in isoantigenic recipients, a marginal marrow stem cell pool may be further depleted to meet these requirements. A similar argument has been

Table 1. Influence of the number of marrow cells transplanted into primary recipients on the ability of the transplanted marrow to promote the uptake of ^{131}IUdR in the spleens of secondary test recipients

Number of cells transplanted into primary recipients	Splenic uptake of ^{131}IUdR (%) promoted by 10^6 cells given to secondary test recipients* Mean values of individual marrow samples	Weighted average, with 95% confidence limits	Percentage of normal,† with 95% confidence limits
5×10^5	0·43, 0·56	0·48‡	56
	0·44	0·42–0·54	50–64
5×10^6	0·74, 0·66	0·68	80
	0·64	0·61–0·76	71–91
5×10^7	1·08, 0·93	0·98	116
	0·89	0·90–1·07	103–131

* The uptake values are given as percentages of the total ^{131}IUdR radioactivity administered, in excess of the percentage retained in spleens of irradiated control animals not injected with marrow.

† The uptake of ^{131}IUdR promoted by normal age-control marrow is reported in ref. 4.

‡ Each value represents results for a single chimera donor; the number of test recipients was 5–10. The pooled average values were weighted for the number of test recipients of marrow for each chimera.

Table 2. Influence of erythrocyte and lymph-node cell transfusions on the ability of transplanted marrow to promote the uptake of ^{131}IUdR in the spleens of secondary test-recipients

Treatment to marrow recipients*	Splenic uptake of ^{131}IUdR (%) promoted by 10^6 cells given to secondary test-recipients† Mean values of individual marrow samples	Weighted av., with 95% confidence limits	Percentage of normal,‡ with 95% confidence limits
Tyrode's solution	0·41, 0·40, 0·41, 0·41	0·42§	39
	0·31, 0·65, 0·44	0·33–0·54	32–48
Erythrocytes	0·66, 1·22, 0·81, 0·96	0·90	84
	0·93, 0·81, 1·02	0·75–1·08	69–101
Lymph node cells	0·39, 1·11, 0·42, 0·96	0·73	67
	0·58, 1·08, 0·97	0·47–1·10	52–85
Erythrocytes and lymph node cells	0·53, 0·43, 0·85	0·78	72
	0·74, 1·25, 1·33	0·49–1·24	57–92

* Treatment was initiated at the time of primary marrow transplantation and continued two or three times weekly until the transplanted marrow was tested for proliferative capacity. This was done 35–40 days after transplantation.

† The uptake values are given as percentages of the total ^{131}IUdR radioactivity administered, in excess of the percentage retained in spleens of irradiated control animals not injected with marrow.

‡ The uptake of ^{131}IUdR promoted by normal age control marrow was 1·08 per cent (95 per cent confidence limits 0·92–1·25). This value represents the weighted average of the uptake promoted by the marrow of 8 normal donors; individual values were 0·79–0·87–1·13–1·18–1·19–1·21–1·32–1·37.

§ Each value represents results for a single chimera donor; the number of test recipients was 5 to 7. The pooled average values were weighted for the number of test recipients of marrow from each chimera.

Table 3. Influence of the recipient's sex on the ability of serially transplanted marrow (from female donors) to promote the uptake of ^{131}IUdR in the spleens of test-recipient mice

Transplant generation	Sex of host	Splenic uptake of ^{131}IUdR (%) promoted by 10^6 cells given to test-recipient mice* Mean values of individual marrow samples	Weighted av., with 95% confidence limits	Percentage of normal,† with 95% confidence limits
First	Female	0·72, 0·48, 0·53, 0·54	0·64‡	59
		0·95, 0·72	0·48–0·84	48–73
	Male	0·41, 0·40, 0·41, 0·41	0·42	39
		0·31, 0·65, 0·44	0·33–0·54	32–48
Second	Female	0·68, 0·59, 0·12, 0·34	0·36	33
		0·25, 0·61, 0·71, 0·12	0·22–0·58	24–45
		0·36, 0·48		
	Male	0·24, 0·02, 0·08, 0·37	0·18	17
		0·11, 0·06, 0·42, 0·37	0·09–0·36	11–25
		0·47, 0·21		

* The uptake values are given as percentages of the total ^{131}IUdR radioactivity administered, in excess of the percentage retained in spleens of irradiated control animals not injected with marrow.

† The uptake values for marrow of age control females are reported in the footnote to Table 2. The value for age control males is not significantly different.

‡ Each value represents results for a single chimera donor; the number of test recipients was 4 to 7. The pooled average values were weighted for the number of test recipients of marrow from each chimera.

proposed to account for the decline in antibody-forming ability of spleen cells after their transplantation into lethally-irradiated mice; it has been suggested that the pool of potentially competent donor stem cells is depleted by stimuli to differentiate[13].

RATIO OF POTASSIUM TO LACTOSE IN COWS' MILK AND ITS GENETIC BASIS

By J. P. WALSH and Dr. J. A. F. ROOK
National Institute for Research in Dairying (University of Reading), Shinfield, Berkshire

IN an earlier communication[1], the lactose and potassium concentrations in the milk of Friesian heifers free from infections of the udder were shown to be constant from the second to about the fifth month of lactation, and an inverse relationship was demonstrated between the concentrations for lactose and potassium obtained with different animals. A more extensive investigation of this relationship and of how it is altered by infections of the udder, by age or stage of lactation has now been made with a group of Friesian heifers held at the Institute farms under controlled conditions of feeding and management and with animals in commercial herds of Friesian cattle. Our observations suggest that, within the breed examined so far, the potassium to lactose ratio in milk has the characteristics of a genetic parameter.

Lactose and potassium concentrations in the milk of individual animals were determined at intervals from the second to the fifth months of lactation. The frequency of sampling occasions varied from 2 in some animals to 7 in others. On each occasion samples representative of the milk obtained from each quarter at successive evening and morning milkings were prepared and analysed.

Lactose and potassium interrelationships. For animals in their first lactation, the means of the concentrations for lactose (g/100 g milk water) and for potassium (mg/100 g milk water) in the milk of all udder quarters found on all sampling occasions to be free of pathogenic bacteria, negative to the Whiteside test[2] and with a cell count of less than 80,000 per ml. of milk, were taken as an index of the potential of the animal. As will be seen later, present or previous bacterial infection of a quarter, which was excluded by the above tests, is associated with a decrease in the concentrations of lactose and potassium and an increase in the concentration of sodium in the milk of that quarter.

The relationship between such values for lactose and potassium for 20 heifers held at the Institute farms and for 76 heifers from eight commercial herds is shown in Fig. 1. Excluding the values represented by open circles for reasons which are discussed here, regression analysis gave the following highly significant ($P < 0{\cdot}001$) relationship:

$$Y = 7{\cdot}4242 - 0{\cdot}01095X \qquad (1)$$

where Y is lactose (g/100 g milk water) and X is potassium (mg/100 g milk water). The standard error of the regression coefficient is $\pm 0{\cdot}00112$ and the standard error of estimate of lactose at a given value of potassium is $\pm 0{\cdot}144$. This equation differs significantly from that of $Y = 8{\cdot}93 - 0{\cdot}0191X$ obtained previously[1]. The discrepancy probably arose because in the earlier work four heifers that had the lowest milk lactose concentrations were from a single herd which proved to have a high incidence of mastitis, and the determined lactose and potassium contents may not have indicated the potential of the animals; the animals were not infected at the time of sampling, but the possibility of damage due to previous infection or injury of the udder was not excluded since Whiteside and cell count tests were not made. When values for the four heifers are excluded, the earlier regression equation becomes:

$$Y = 7{\cdot}2534 - 0{\cdot}00983X \qquad (2)$$

The standard error of the regression coefficient is $\pm 0{\cdot}00187$ and the equation does not differ significantly ($P > 0{\cdot}05$) from that for the present results.

Of the five animals for which values are represented in Fig. 1 by open circles, the four grouped together were the entire heifer population of one commercial herd, the fifth was purchased in-calf with other heifers and held at an Institute farm throughout the first lactation. All five animals had sodium contents in their milk higher than

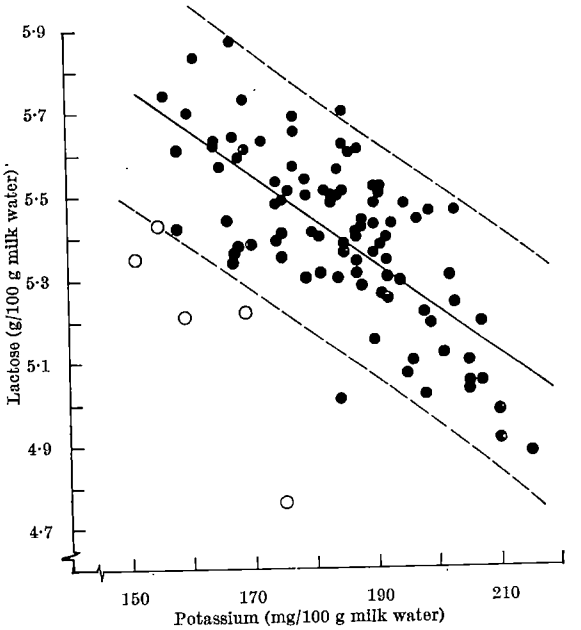

Fig. 1. Relationship between the lactose and potassium contents of the milks of heifers in mid-lactation and free from infections of the udder. The line is $Y = 7{\cdot}4242 - 0{\cdot}01095X$ ($P < 0{\cdot}001$) and relates only to the values represented by closed circles. The broken lines indicate the 95 per cent confidence limits for lactose at given values of potassium. (See text for explanation of values represented by open circles)

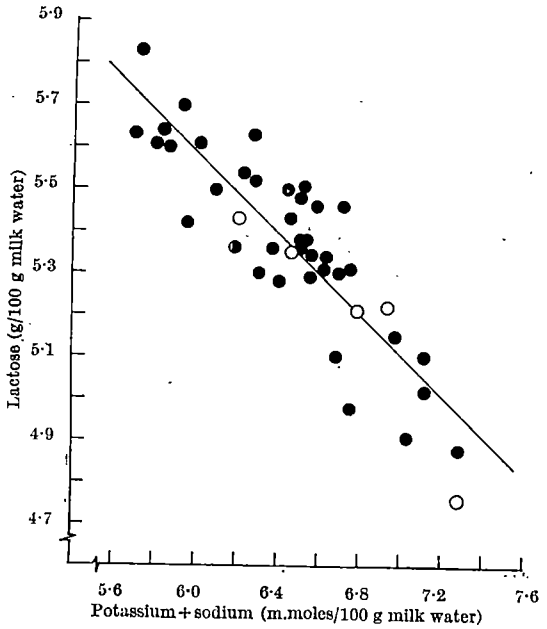

Fig. 2. Relationship between the lactose and the sodium plus potassium contents of the milks of heifers in mid-lactation and free from infections of the udder. $Y = 8{\cdot}456 - 0{\cdot}4785Z$ ($P < 0{\cdot}001$). (See text for distinction between closed and open circles)

was considered normal for heifers in their first lactation, and yet, from inter-quarter comparisons of milk composition and bacterial tests, there was no evidence of udder damage. This apparent distinction disappeared, however, when lactose content was related, not to potassium content but to the equimolar sum of sodium and potassium contents in the milk of these five animals and of other heifers for which information on sodium content was available (Fig. 2). The following highly significant ($P < 0{\cdot}001$) equation was obtained:

$$Y = 8{\cdot}456 - 0{\cdot}4785Z \qquad (3)$$

where Z = potassium + sodium (m.moles/100 g milk water). The standard error of the regression coefficient is $\pm 0{\cdot}0446$.

The empirical relationship between the concentrations of lactose and potassium in milk arises, therefore, because, for the majority of Friesian heifers free from udder disease, variations from animal to animal in the concentration of sodium in milk are small relative to variations in potassium concentration.

Effects of infections of the udder, stage of lactation and age. Lactose and potassium concentrations in the milk from quarters damaged by bacterial infection or physical injury, or in the milk of an animal at an early or late stage of lactation or beyond its first lactation, are seldom the same as those found in the milk from infection-free quarters in the middle part of the first lactation. Each of the effects tends, to varying degrees, to cause a decrease in the concentrations of lactose and potassium and an increase in sodium. Moreover, the resulting changes in the lactose to potassium plus sodium ratio are not distinguishable from the inherent differences in the ratio described by equation (3). The empirical relationship between the lactose and potassium contents of milk secreted by healthy quarters of the udder of cows in the middle part of the first lactation appears to apply, however, to most of the Friesian cattle so far examined. If it could be shown that, while the concentrations of lactose and potassium in milk are depressed by various physiological factors, the ratio of lactose to potassium is unaltered, this ratio would provide a basis for predicting a 'potential' lactose content in cattle of all ages, irrespective of their stage of lactation or presence of infections of the udder.

Barry and Rowland[3] have shown that infections of the udder and advancing lactation cause similar reductions in lactose and potassium contents of milk, but comparable information on the effect of age is not available. We have confirmed that the ratio of potassium content to lactose content in milk is little affected by infections of the udder (Fig. 3), by stage of lactation except during the first few days or the last two months of lactation (Fig. 4), or by age in a single cow in which this effect has been examined.

Prediction of a 'potential' lactose content. In commercial herds of Friesian cattle in which the performance of the heifers is found to conform with the relationship expressed in equation (1), the ratio of potassium content to lactose content in the milk of each of the animals of the herd can therefore be used to predict the 'potential' values for potassium and lactose contents defined by equation (1). Graphically the potential values will be determined by the intercept of the regression line of Fig. 1 with a second line extrapolated from the graph origin, describing the given ratio of potassium to lactose. For lactose content calculation would be made according to the formula:

$$\frac{7{\cdot}4242}{1 + (0{\cdot}01095)R}$$

where R is the ratio of potassium (mg/100 g milk water) to lactose (g/100 g milk water) found in the milk.

Genetic basis of the potassium to lactose ratio. For all animals, including heifers, the ratio of potassium content to lactose content was calculated as the mean for the values of all udder quarters, including those known to

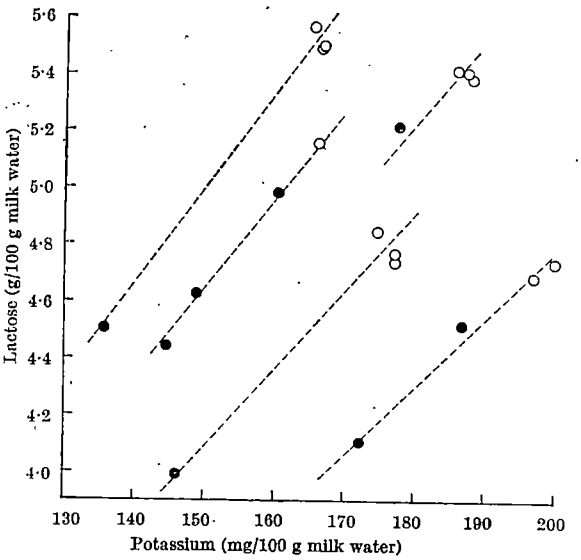

Fig. 3. Relationship between the lactose and potassium contents of the milks from the separate quarters of the udder for five cows in mid-lactation. ○, non-infected quarters; ●, infected quarters. The broken lines describe a constant potassium to lactose ratio

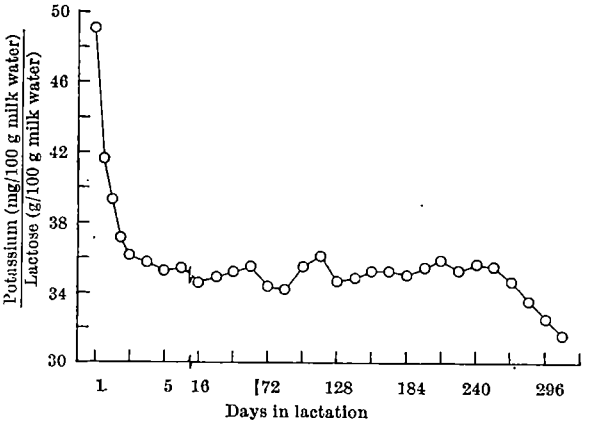

Fig. 4. Changes with stage of lactation in the potassium to lactose ratio in milk. Each value is the mean for six heifers free from udder infections

Table 1. The ratio of potassium (mg/100 g milk water) to lactose (g/100 g milk water) and the predicted lactose potential (g/100 g milk water) in the milk of eight pairs of monozygous (*M.Z.*) cattle twins

have infections, on all sampling occasions. The predicted potential lactose content was calculated using the formula.

The results obtained with eight pairs of monozygous twins held at the Institute farms throughout their first lactation are given in Table 1. The lactose potential is predicted only for the Friesian animals, since it is not yet known whether the relationship expressed by equation (1) applies to animals of other breeds. The heritability of the potassium to lactose ratio estimated from the values for the monozygous Friesian pairs was 0·95. However, this estimate includes correlations between twins due to common pre- and post-natal environment and to dominance and non-additive gene interactions[4].

Additionally, therefore, the records of 29 dams and their 46 daughters present in seven of the eight commercial herds examined were used to estimate the heritability of the potassium to lactose ratio. The results for animals from the eighth farm were excluded since this was the herd that contained the four heifers that gave a characteristically different relationship between lactose and potassium.

A calculation of the within herd regression of daughter group means on the records of their dams gave a heritability estimate of $h^2 = 0{\cdot}95 \pm 0{\cdot}270$. On the assumption that environmental correlation between maternal half-sibs would be small, heritability was also calculated by repeating the record of the dam with each of her daughters in an analysis of co-variance of dams and daughters[5]. The within-herd regression coefficient of daughters on dams was $b = 0{\cdot}38 \pm 0{\cdot}119$, giving a heritability estimate of $h^2 = 0{\cdot}76 \pm 0{\cdot}238$. A comparison of the variance of daughters about their regression on dams with the variance within dams confirmed that there was very little environmental correlation between daughters of the same dam.

The total variance of the potassium to lactose ratio within the population (σ_p^2) is calculated as[5]:

$$\sigma_p^2 = \frac{\text{variance about dam-daughter regression within herds}}{1 - b^2} = 4{\cdot}8$$

These observations suggest that the potassium to lactose ratio and the predicted potential for lactose content in the milk of individual animals are largely independent of the effects of environmental factors and of physiological changes associated with age or stage of lactation, and serve to characterize the genetic potential for lactose content. The use of this concept in examining the relative importance of inherent and environmental factors in determining the milk composition of dairy herds is now being examined.

We thank Dr. R. N. Curnow and Dr. S. J. Rowland for their advice. One of us (J. P. W.) acknowledges a junior research scholarship from An Foras Talúntais, Dublin.

GALAPAGOS TORTOISE AND MARINE IGUANA DEEP BODY TEMPERATURES MEASURED BY RADIO TELEMETRY

By Prof. R. STUART MACKAY

Medical Physics Division, University of California, Berkeley

As a member of the recent Galapagos International Scientific Project, it was possible for me to make some observations on two unique animals in their natural habitat. Some new types of information were obtained through the use of small radio transmitters which were swallowed by the animals, thus allowing them freedom to move about in a relatively normal physiological and psychological state during the monitoring process. The circuits used will not be given here, since they have already been discussed in the literature, starting with the original article on biological telemetering of internal information[1]. These methods have been summarized[2], brought up to date[3], and methods relevant here for dealing with aquatic animals given[4].

One species examined in this manner was the giant tortoise *Geochelone* of Indefatigable Island (also known as Santa Cruz Island). Particular attention was directed to an animal weighing 65 kg and one weighing 170 kg, each of which was examined for about a week after it had ingested a frequency-modulated temperature-telemetering radio transmitter. These transmitters were approximately spherical and about 1 cm in diameter. Their components were embedded in plastic material and covered with silicone rubber to minimize damage by chewing, or being dropped or walked on; these last factors are important in field work with wild animals.

Two methods of feeding proved effective. One was to push the transmitter into a banana, which was then ingested as a preferred food by the animal during its customary morning feeding. Alternatively, when an animal was placed on its back and a foot tickled, it would hiss, during which time the transmitter could be dropped into its upper jaw, whence it would be swallowed. The animals, which were examined in detail, were free to roam in natural surroundings, but were confined to a general region approximately 100 m on a side by a wall of loose stones. At intervals of 1–4 h they were approached with a radio receiver the signal of which indicated deep body temperature, and simultaneous readings of shell temperature and ambient conditions were made with a thermistor probe. Results for the larger animal are given in the upper part of Fig. 1; those for the smaller one were similar.

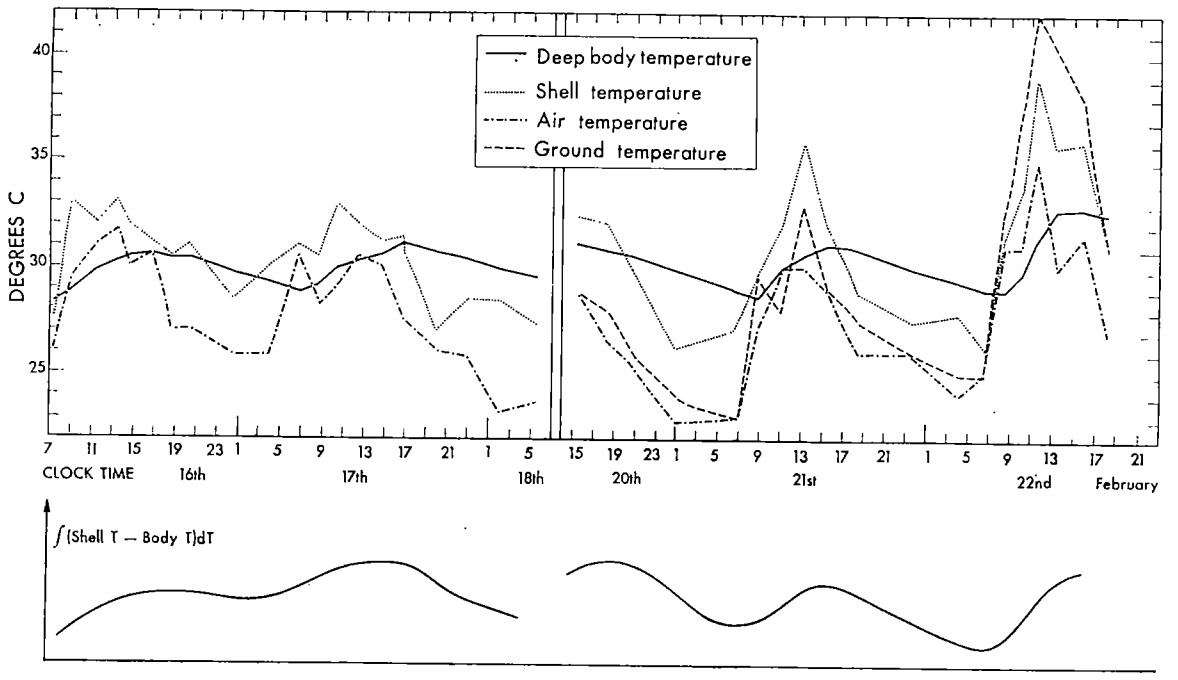

Fig. 1. Temperature cycles in and about a 170-kg tortoise relatively free to move about in or out of sunlight according to its choice. Below is shown the calculated pattern of heat flow which resembles the telemetered core temperature; this suggests that most of the body of the animal is at the same temperature, rather than having heat flowing throughout its mass by diffusion

A few general words about the apparatus might be mentioned. The transmitter circuit was actually the original one tested in human beings[1], with the temperature being transmitted as a rate of arrival of pulses as the transmitter periodically turned itself on and off. The main circuit modification was to use a two-microfarad tantalum condenser in the base connexion of the transistor so that the pulses were generated approximately once a second. Thus they could be timed with a stop watch, as has recently been described[4]. This also led to rather low average current consumption, and continuous transmission for several weeks was demonstrated. Power was low enough to avoid any local diathermy heating. Transmitter calibration by exposure to known temperatures gave temperature as a non-linear function of click rate; a given set of results can be plotted as clicks per second, or as seconds per click, and will generally appear more linear one way than the other, although the overall result is unaffected. An unmodified standard pocket transistor receiver was used to detect the signals, as a further effort towards simplicity and ruggedness. This receiver was selected by entering a radio store with a small transmitter in a pocket, and noting which receivers were most sensitive; cost, size and sensitivity appeared unrelated. The brief transmitted pulses were detected for a wide range of tuning settings, and thus the receiver was simply tuned between commercial radio stations. On the Galapagos Islands where there is no commercial radio, this was only a factor at night when distant transmissions could be detected.

In the upper part of Fig. 1 is a plot of the results from the observations on the larger animal. The air and ground temperatures were similar. Because the region of the experiment was relatively sheltered, the air at the level of the tortoise would be expected to come into thermal equilibrium with the ground. Temperature of the tortoise was usually higher than these temperatures. The shell temperature is seen to cycle up and down about the deep body temperature, sometimes being higher and sometimes lower. The shell temperature shown is an average from several observations taken at different points on the shell. The animals' pattern of activity was usually to spend the night immobile under a bush or tree. When the Sun appeared, they would normally walk around exposed for a few hours while eating, and then return under a bush, from which they would occasionally wander during the rest of the day. The irregular fluctuations in shell temperature reflect this irregular exposure to the Sun and shade. Using the radio receiver in the fashion of a direction-finder showed that, in the several days during which observations were taken, the transmitter did not move significantly within the body of the animal (though after a few weeks such a transmitter can pass normally), and thus the results labelled 'deep body temperature' are consistent. The pattern was similar on a day when no food was ingested, and thus the temperature cycle does not seem due to such things as the fermentation of food in the stomach.

Several general patterns seemed evident. When the animal was free to move about as it wished, its body temperature varied by only a few degrees. These cyclic attenuated temperature fluctuations appear related to changes in temperature on the shell, but with maxima delayed in time by 5–6 h. There are periods when the upper shell temperature is greater than the temperature nearer the animal's centre, which temperature is greater than the ground temperature. At this time, some heat is simply flowing in through the top of the animal and out through its underside. It is clear that blood supply to the limbs did not serve as a heat exchanger to bring the body temperature rapidly to that of the ground or air.

One might expect the temperature of these large animals to remain relatively constant because of thermal inertia associated with their mass, or that, because of their size, temperature changes would take a long time to arrive, if they did at all. Comparison might be made with the heating and cooling of a sphere of water having the same mass. But results recorded here indicate that this could be unrealistic. It does not appear that waves of heating and cooling travel by thermal diffusion through the animal's body, as will be seen from the following. The changes in temperature deep in the animal's body are not abrupt enough to be associated with a simple time delay by diffusion. The results shown are consistent with a representation involving a single time constant. For those who find electrical analogies useful, it is as if

heat were flowing through a resistance to a large central region according to the same equations by which a single condenser charges through one resistor. This is not the way diffusion of heat over relatively great distances would affect core temperature. If heat is thought to flow inward to warm the core of the animal under the 'driving force' of the difference in temperature between shell and core, then the rate of change of temperature deep in the body would be the difference in temperature between surface and core. It would then be expected that the integral of the difference in temperature between inside and outside, with respect to time, would be a curve which resembles deep body temperature. In spite of the limitations of the data, this is seen to be largely true in the lower part of Fig. 1, where the result of a graphical integration is plotted. Also, lack of overall slope suggests that any new outward flow of metabolic heat through the upper shell was relatively small (though some average flow down to the cooler earth must have existed).

These results do not seem to describe a distributed diffusion effect, but rather heat flow through a limited region having a high resistance compared with that of the material absorbing the heat. It seems probable that what happens is that heat flows through the thermal resistance of the animal's shell and into its body tissues, where it is rapidly distributed, all the latter warming and cooling together because of the 'stirring' effect of the flow of blood. A measurement of shell conductivity would allow these same results to be used to calculate that fraction of the total mass of the animal which is involved in this 'stirring'. This particular arrangement of thermal properties would seem to be useful to the animal in that it would allow all its body tissues to be at a 'comfortable' temperature, and would allow temperature regulation by a 'shot' of heat from the Sun or cool from the shade, rather than having a temperature wave moving in. It is interesting to speculate if perhaps dinosaurs were able to use a similar mechanism, possibly involving tissue layers with differing degrees of blood supply.

Temperature cycles also were observed in the marine iguana, a cold-blooded animal which complicates its thermal life by entering the cool ocean to eat seaweed. It seemed important to follow 24-h cycles in a single animal, while interfering with its activities as little as possible, and thus radio telemetry was used. Two transmitter types were used to provide for two types of experiments, and these combined to give an indication of what *Amblyrhynchus cristatus* from Academy Bay can choose to do.

Since Darwin's time, it has been said that marine iguanas do not bite. Though their dispositions seemed better than those of the land iguanas, this is not strictly true. When caught by the tail with the hand, or noosed, they would often attempt one bite and then calmly relax. The method used to feed the same type of transmitter as already mentioned here to these animals was to hold them by the tail and let them bite on a piece of wood held to the side of the head. This was then twisted, without damage to the teeth, and the transmitter dropped into the mouth. Gentle stroking of the throat produced swallowing. Pieces of coral the size of these transmitters were occasionally found in the fæcal matter of these iguanas, and so this experiment was not felt to impose any unnatural or dangerous circumstances. These small transmitters have a transmission range of only approximately one metre, and thus, though they can give information about inaccessible animals, for example, burrowed in crevices in the lava, they are extremely inconvenient to use with an animal that is not confined to some relatively small general area. A 4-kg male was placed in a cage 2 m × 4 m in which there were both exposed regions and shade throughout the day. At the time of the year at which this investigation was made, in connexion with the breeding season, the animals did not enter the water to eat every day. Thus it was felt that the results depicted in the upper half of Fig. 2 are probably representative of the temperature cycle which this animal would have provided for itself if completely unrestrained by any boundaries. At the end of this experiment, this animal was killed in connexion with another experiment. The transmitter was found to have passed just slightly beyond the level of the diaphragm, and the rest of the intestine was still packed with seaweed. Thus the animal could not have been hungry, and the transmitter had remained essentially fixed within the body during the course of these observations. In Fig. 2 also is shown the cycle of air temperature as recorded in a standard way by a weather station a few hundred metres away. This last is suggestive of, but is not completely equivalent to, observation of the immediate ambient conditions.

A second transmitter type having considerably more power was used to make an observation on a completely unrestrained animal. The electronic circuit was quite like that recently described for telemetering from within a dolphin[4], except that a 7-cm diameter loop antenna was used to radiate the signal. Twenty msec pulses of 600-kc/s radio energy were radiated at a rate which indicated temperature. A higher frequency would have carried the signal further with a smaller antenna; but this lower frequency was chosen for its greater ability to penetrate ocean water. These pulses tuned sharply on one of the pocket receivers already mentioned here. A trivial circuit modification was made to introduce a 'local oscillator' which, by beating with the incoming pulses, gave a more noticeable audible signal. The range of this combination was approximately 30 m. At this range, it was possible to track the animal through a mangrove tangle, while simultaneously monitoring its temperature, though it was out of sight.

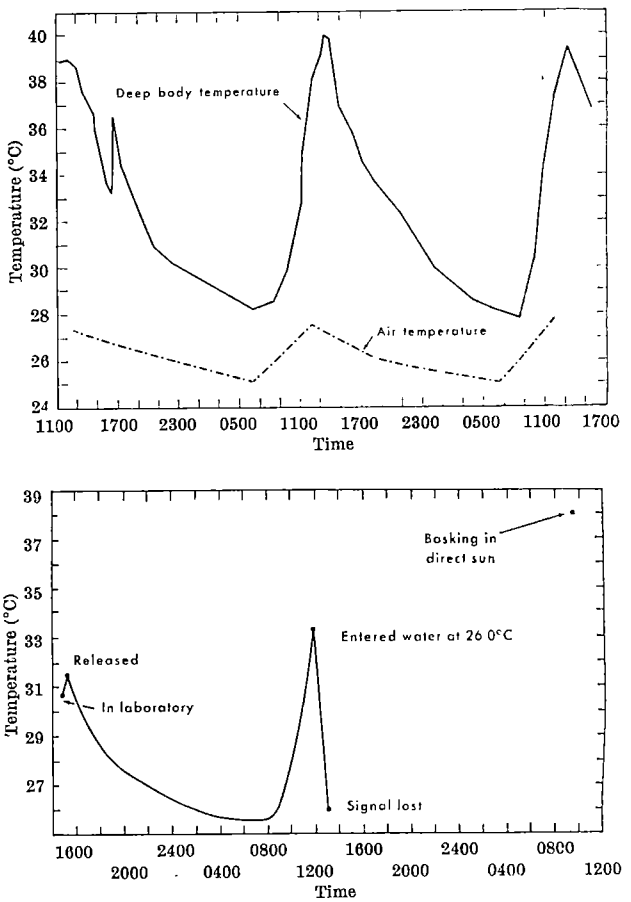

Fig. 2. Internal temperature telemetered from a marine iguana in a large cage (top), and from an unconfined one (below). In this case, air temperature was not taken in the immediate vicinity of the animal

This transmitter was too large to be swallowed, the components occupying about 10 c.c., and so it was attached to the side of the base of the tail, where it would scarcely interfere with swimming or with crawling into crevices. The unit, with a hollow cover to give neutral buoyancy in water, was held in place with two loops of plastic 'Ident-a-Band', over which was placed a layer of ordinary adhesive tape. The loop antenna was held flat across the back of the animal by a band. Temperature was sensed by a thermistor at the end of a catheter, the transmitter itself being insensitive to temperature. Rather than placing this in the usual opening where muscular contractions might have expelled it, it was inserted into the abdominal cavity through a small puncture in the body wall. This wound seemed less severe than some the animals inflict on each other during various disputes. A layer of collodion sealed the probe in place. When the unit was removed a few days later, the animal appeared normal and healthy, and when it was sighted during the next few days, it appeared to remain so. Its temperature history during this period is shown in the lower half of Fig. 2.

When on land, this animal warmed and cooled in an expected way. It might be thought that by sufficient advance warming, it could remain warmer than the ocean during a brief swim, and that holding the head out of the water might supply a bit of extra heat to further delay cooling. However, observation of the actions of these animals suggested that they probably were in the water for longer than any likely thermal time constant, and thus probably cooled down fully. In the case of the foregoing animal, which entered water at 26° C, its telemetered temperature indeed indicated that it had cooled to exactly 26° C while remaining quite active. In the course of this observation, the animal signal was lost; the radio system found it again in an unexpected location the next day.

Thus these two species are seen to act in quite different fashions, the tortoise having a relatively constant temperature while the iguana functions under conditions of relatively large temperature fluctuations during each 24-h period.

I thank the Directors of the Galapagos International Scientific Project for inviting me to attempt these observations. Other scientists there were helpful with their time and advice, and I thank Drs. R. Stebbins, H. Dowling, G. Bartholomew and J. Hendrickson, especially, who were also carrying out investigations on these same animal types. I thank Jean Mackay and Donald Dietlein for assistance in handling the animals and in obtaining the results.

AGE OF CALEDONIAN OROGENY AND METAMORPHISM IN BRITAIN

THE re-interpretation of British Caledonide chronology by Fitch, Miller and Brown[1] (hereinafter referred to as "the authors") rests on a hypothesis which may be expressed in two parts, namely: (*a*) "A pre-(720–765) m.y. orogeny produced a complex of Moinian, Dalradian and Monian regionally metamorphosed rocks, with migmatites and acid intrusives. On this basement were deposited the Eo-Cambrian and Lower Palæozoic rocks of the Caledonian geosyncline"; (*b*) "The main orogenic event that involved the whole Caledonian system did not begin until late in the Silurian". Both these are open to criticism on purely stratigraphic grounds.

The north Irish–Scottish Lower Dalradian succession contains a well-known boulder-bed, which outcrops at intervals for more than 300 miles along the strike. This formation has many of the characters of a tillite. Elsewhere in the Caledonian province well-developed tillites are known. Harland[2] refers to tillites in the Hecla Hook complex of Spitsbergen as equivalent to the Upper Eleonore Bay tillite horizon of Greenland, and to the Varangian and Sparagmitian tillites of Norway. Troelson[3], discussing the Cambrian of north Greenland and Ellesmere Island, places the tillite horizon at the base of the "Eo-Cambrian". Holtedahl[4] similarly places the lower boundary of the Norwegian Eo-Cambrian below the Moelv conglomerate, considered to be a tillite, and the Moelv sparagmite. Fossiliferous Lower Cambrian here lies conformably above the Eo-Cambrian, as is generally the case in the Caledonian province where both units occur together. Pruvost[5] refers to fossiliferous Middle Cambrian resting, in north-west France, on the metamorphosed, tillite-bearing "Infra-Cambrian" Brioverian complex. It seems probable that all these tillite, or tillite-like, horizons are stratigraphically correlatable, and that they represent a synchronous event, or sedimentary state.

The authors' argument requires the whole of the metamorphic Dalradian to be pre-Eo-Cambrian (which they do not define). This, on the evidence at present available, appears to be unlikely. (It is instructive to note that as long ago as 1930 Peach[6] suggested that part of the Dalradian succession on Islay and the adjacent islands might be Cambrian, and that the base of the Cambrian might well be drawn at the horizon of the Port Askaig conglomerate (tillite). More recently, Hupé[7] has shown that the Lower Cambrian of Morocco contains four trilobite zones below the equivalent of the north-west European *Callavia–Holmia* zones. The Caledonian fossiliferous Lower Cambrian may thus be stratigraphically some way above the base of a notionally complete Lower Cambrian sequence, and the gap could well be filled by part, or all, of the Eo-Cambrian. Rudwick[8] has suggested that the apparently synchronous appearance of skeleton-bearing invertebrates in the Lower Cambrian may be explicable in terms of the climatic amelioration following the Eo-Cambrian glacial episode.)

The Lower/Middle Cambrian trilobite *Pagetia* found by Pringle[9] was ambiguously described by him as from "the Highland Border rocks", and not, as the authors state (*op. cit.* 276–7), from the Highland Border Series, although such an attribution may have been implied in Pringle's report. Stone[10] has shown that the Leny Limestone group, from which the fossils came, is an integral part of the Upper Dalradian succession below the Leny Grits. If the fossil evidence is accepted, and taking into consideration the fact that the whole of the Dalradian is regionally metamorphosed, it follows: (*a*) that some part of the Dalradian is of Lower Cambrian age; (*b*) that at any rate this part of the Dalradian was metamorphosed after late Lower/early Middle Cambrian time, and not, as the authors' hypothesis requires, before the Cambrian and Eo-Cambrian.

Stratigraphic and structural evidence for a pre-Arenigian Caledonian metamorphic/tectogenic episode has been assembled by Dewey[11], with special reference to west Ireland. It is necessary to direct attention to certain misinterpretations which are becoming embedded in the literature as a result of Dewey's conclusions, and which appear to have been accepted by the authors. Dewey

himself states clearly (*op. cit.* 399): "Nowhere in W. Ireland is the contact between the Arenig and the Dalradian seen, and therefore there can be no precise definition of its nature". In fact, the contact is always either faulted or obscured by igneous intrusion, and the significance of this has not yet been elucidated (it might, for example, be a horizon of décollement). The statement by George[12], following Dewey, that "the southernmost tracts of the Connemara schists, continuing towards Galway, carry unwarped Arenig rocks preserved on their surface . . ." is misleading. Dewey's interpretation is based, for this detail, on the work of McKie and Burke[13], who write: ". . . the low degree of deformation, evidenced particularly by the excellent preservation of sedimentary and pillow structures, suggests that the South Connemara Series is unlikely to be pre-Cambrian; it would thus appear to belong to some part of the Ordovician". After making comparisons with the nearest Ordovician outcrops, they conclude by making "a tentative identification of the South Connemara Series with part of the Arenig to Llandeilo stages of the Ordovician". It must also be repeated that the contact between the South Connemara Series and the Connemara schists (? Dalradian) is not seen. The evidence for pre-Arenigian metamorphism of the Connemara schists is thus stratigraphically circumstantial, not direct.

The authors reject the possibility of an important orogenic event having occurred at or about the time of the "Arenig" transgressions of which there are stratigraphic records, because the likelihood that "such an event, accompanied by recumbent folding on the grand scale, could have been closely restricted to the Dalradian belt and have left the rest of Britain unaffected, is to us unacceptable" (*op. cit.* 277). The authors do, however, accept the bone-bed (less than 1 ft. thick) at the top of the Ludlovian Aymestry Limestone of the Welsh Borderland as representing "the initiation of the culmination of the Caledonian evorogeny". It will be useful to compare this type of stratigraphic 'event' with evidence for others tending to support an alternative hypothesis of crustal deformation at other levels within the Lower Palæozoic succession, and, in particular, within the Ordovician.

On the platforms marginal to the Lower Palæozoic mobile belt there is a stratigraphic break within the Cambrian: in north-west Scotland this takes the form of the apparent absence of Middle Cambrian beds; in Shropshire there is a minor unconformity at the base of the Middle Cambrian. In Ireland, slide-conglomerates of pre-*extensus* age (Dewey, *op. cit.*), that is, either early Arenigian or pre-Arenigian, and a widespread pre-Caradocian unconformity[14], indicate crustal instability. A similar unconformity is present within the Scottish Highland Border Series[15]. Farther south, in the Girvan–Ballantrae region, important conglomeratic units lie uncomformably on the Arenigian (in part) Ballantrae Volcanic group[16]. These, and later, Silurian, conglomerates contain large amounts of basic igneous debris which Black[17] considers to have been derived from a northerly extension of the Ballantrae Volcanic group, possibly beyond the Highland Border fault. Black emphasizes the need to postulate severe diastrophism in the Arenigian–Caradocian interval to account for these observations. Bloxam and Allen[18] have shown that the glaucophane-schists and associated rocks of the Girvan–Ballantrae complex suffered the more intense of two deformations in pre-Caradocian, possibly post-mid-Arenigian, time, but not pre-Cambrian as previously supposed.

In north England, the ejection and accumulation of up to 12,000 ft. of mainly andesitic material—the Borrowdale Volcanic group—during the late Llanvirnian–Llandeilian, suggest some local crustal instability, the scale of which is further indicated by the observation that, in places, the whole of the volcanic group, together with part of the underlying clastic Skiddaw group, had been eroded before the Caradocian. George (*op. cit.*), quoted by the authors in support of a late Silurian orogenic event involving pre-Devonian fold-amplitudes of 10–15,000 ft. in the Scottish Midland Valley, writes: "The combined thickness of the Skiddaw and Borrowdale groups is not less than 22,000 ft. and may well exceed 24,000 ft. This gives a measure of amplitude of the pre-Bala [*sc.* pre-Caradocian] folds—*not greatly exceeded in post-Silurian deformation*" (my italics).

In Wales almost the whole of the Ordovician succession is marked by volcanic rocks in one region or another, from the post-Tremadocian pre-Arenigian Rhobell Fawr group to the Ashgillian Cyrn-y-brain rocks, and no fewer than three unconformities can be traced—pre-Arenigian, pre-Llandeilian, and pre-Caradocian. Throughout the succession the pattern of sedimentation is suggestive of severe crustal instability in the source areas[19].

Evidence from the nearest European major part of the Caledonian province is relevant here. In north-west Norway, Kvale[20] refers to deformation and metamorphism of Lower/Middle Ordovician age, followed by uplift and erosion. In central Norway, Strand[21] refers the emplacement of the lower Jotun nappe to a time between mid-Ordovician and early Silurian. The succession in the Trondheim region, described by Vogt[22], shows important conglomeratic horizons, recording diastrophic 'phases', of early/mid Ordovician (Trondheim phase), mid/late Ordovician (Ekne phase), and late Ordovician/early Silurian (Horg phase) ages.

The weight of the stratigraphic evidence thus points to an important tectogenic, possibly metamorphic, event-sequence of post-early/middle Cambrian, pre-Silurian age, which caused widespread sedimentational and structural disturbance. Shackleton[23] remarks on the absence of a molasse (that is, post-orogenic) element in the post-Dalradian sedimentation pattern: it is terminologically improper, but perhaps illuminating, to regard the main part of the British Ordovician and Silurian sedimentary succession—and particularly the post-Llandoverian Silurian—as "molasse in flysch facies".

In conclusion, some comment is offered on the authors' use of Simpson's[24] terms "evorogeny" and "parorogeny", and their derivatives. The authors use these terms in relation to the Caledonian mobile belt, not in Simpson's sense as distinguishing geosyncline from "shelf", but rather as distinguishing the metamorphic from the non-metamorphic part, and treating this latter as if it had "shelf" characteristics. It is, of course, well understood that this part of the Caledonian complex is very far from the accepted notion of the "shelf", except along its outermost margins, and momentarily and over small areas elsewhere. I prefer, and have for some years used, the term "para-orogenic" to label the non-metamorphic part of the British Caledonian complex, which differs from the eu-orogenic part in lacking not only high-grade regional metamorphism, but also a migmatite belt, "alpine" structures, and a serpentine belt in the sense of Hess[25]. The minor diastrophic and sedimentational effects observed on the marginal "shelves"—or, preferably, platforms, since the word "shelf" has more precise geomorphological connotations—have for long been called "epeirogenic", and there seems no need to depart from this. For the case of a region of moderately heavy sedimentation, which later suffers moderately severe deformation, intermediate, that is, between the eu-geosyncline and the platform, I use the term "coelogenic" (basin-producing). This term has the advantage of directing attention to the greater heterogeneity of conditions along the strike, as compared with the greater uniformity in the eu-geosyncline.

Although, no doubt, orogenic, para-orogenic, coelogenic, and epeirogenic deformational events must be linked in some fundamental diastrophic process, there is no justification, as Simpson (*op. cit.*) points out, for Stille's assumption—which has wide acceptance, including, apparently, the authors'—of synchroneity and corre-

spondence between periods of movement and quiescence in the geosyncline and elsewhere. On the contrary, the pattern in most mobile belts appears to have been one of patchiness and migration, both of deformation and metamorphism, in space and time. The Caledonian belt would seem, on the stratigraphic evidence at present available, to conform to this generalization rather than to the "terminal" orogenic pattern proposed by the authors.

Any hypothesis regarding the age of Caledonian orogeny and metamorphism in Britain can be criticized on "purely stratigraphic grounds" because our stratigraphical knowledge, being incomplete and ambiguous, can be used to support various alternative interpretations. Until stratigraphers can produce convincing definitive evidence regarding the age relationships of British Caledonian rocks, it is necessary to pursue a "multiple working hypothesis" approach to the problems of British Caledonian geology.

We are continuously reviewing the various hypotheses of Caledonian evolution, including that put forward by Dr. T. G. Miller, against the background of a rapidly expanding volume of new isotopic evidence. In our paper[1] we make it clear that the hypothesis discussed is no more than the "working hypothesis at present favoured by us", and that, so far, we have not been able to produce unambiguous isotopic evidence of Pre-Cambrian metamorphism of Dalradian rocks. We are familiar with the evidence that suggests major Caledonian orogeny at the end of the Cambrian or in mid-Ordovician times, and with the stratigraphical evidence in favour of a part Cambrian age for the Dalradian. Unfortunately, the stratigraphical evidence regarding the age of the Dalradian does not enable a convincing conclusion to be reached. The evidence of boulder-beds can never be conclusive: apart from the difficulty of demonstrating whether or not any given boulder-bed truly represents a tillite horizon, in the various late Pre-Cambrian successions mentioned by Dr. T. G. Miller, there are several such beds.

A simple correlation of all of these boulder-beds over the very long distances involved can be no more than tenuous hypothesis, however intellectually satisfying. We feel that the evidence is against such a simple correlation. In this context, it is salutary to recall a more recent opinion expressed by Harland[2], who, after discussing the well-known correlation favoured by Dr. T. G. Miller, said, "However, in addition to one very good double tillite in the Arctic, a lower one has been found, low in the Greenlandian succession, and there seemed evidence of lower ones elsewhere. At the same time, Sutton and Watson have described a boulder-bed from the Banffshire coast much higher in the Dalradian. Since there does not seem to be any well-authenticated tillite in Cambrian or Ordovician times, the serious possibility must be considered that most of the Dalradian is Pre-Cambrian, like the Hecla Hoek and Greenlandian". While agreeing to the plausibility of the correlations suggested by Dr. T. G. Miller, we feel it equally possible that the Moine, Dalradian and Monian rocks of Britain find their equivalents in the Greenlandian of the Carolinides of north-eastern Greenland, and that the Eo-Cambrian (or, more strictly, the sub-Cambrian/post-Carolinide fill of the various Caledonian sedimentary basins along the strike of the mobile belt) is thin or absent in Britain, as the Caledonian rocks are across parts of the older Carolinides belt in east Greenland. There is nothing in the published work of Pringle or Stone that proves conclusively that the fossils found by Pringle came from rocks which form "an integral part of the Dalradian succession". Faulted ground, lithological correlation and structural hypothesis are involved. The continuity and correlation of the various successions within the Dalradian area can also be questioned. If a Cambrian age for a real part of the Dalradian succession could be unambiguously demonstrated, we should most gratefully welcome it.

Dr. T. G. Miller is under the erroneous impression that we reject the possibility of orogenic events at the end of the Cambrian and at other times during the Lower Palæozoic. On the contrary, we are aware of a valid stratigraphical record of numerous episodes of crustal unrest within the British sector of the Caledonian mobile belt, the more important of these occurring in late Pre-Cambrian/early Cambrian, mid-Cambrian, late Tremadocian/early Arenig, mid-Ordovician, late Ordovician/early Silurian, mid-Silurian, late Ludlovian/early Downtonian and mid-Devonian times. We agree that magmatism must be closely related to tectonism, and that the widespread volcanism of the Ordovician must reflect deep-seated crustal instability. What we did suggest, however, as the basis of our working hypothesis, and because we believe that it can be demonstrated from the isotopic evidence, is that the culminating, paroxysmal, Caledonian orogenic/magmatic/metamorphic event in Britain occurred (as in East Greenland[3]) around (420–410) $\pm$ 10 m.y. British Caledonian plutonic magmatism is associated with this event and not with the earlier para-orogenic events. When present dating programmes are completed, it will be possible to suggest dates for some of the earlier Caledonian orogenic events and to discuss alternative interpretations of the overall orogenic time-pattern more conclusively.

We feel that the stratigraphically circumstantial evidence for pre-Arenig metamorphism of the Connemara schists (and therefore of the Dalradian) is more convincing than Dr. T. G. Miller admits. To ignore structural or isotopic evidence unless it confirms or can be confirmed by palæontological stratigraphy is to be unnecessarily cautious. With regard to the evidence of the Ludlovian Bone Beds, it cannot be expected that the sedimentary record outside the mobile belt will be as dramatic as that within it. Our use of the terms evorogenic and para-orogenic is closer to their use by Simpson than to the meanings suggested by Dr. T. G. Miller. We use the term evorogenic when describing the major culminating structural events in the history of a mobile belt and para-orogenic to describe less-important events that may occur either within the constituent geosynclinal basins of the belt or on the adjacent stable or unstable shelves. Where we differ from Simpson is in our interpretation of the

time-sequence of development of the evorogenic structures.

Finally, we would like to point out that our acceptance (as a working hypothesis) of a general contemporaneity between sequences of distinct episodes of increased intensity of crustal instability, both within and along the margins of particular active zones, stems from our attempt at a rational interpretation of the isotopic evidence from the Caledonian and other systems[4], and not from an uncritical acceptance of Stille's at present unfashionable concepts. Dr. T. G. Miller's conclusion, that the pattern of tectonic and metamorphic activity in mobile belts is one of incomprehensible patchiness and migration in both space and time (despite his earlier insistence on the contemporaneity of certain stratigraphical events over great distances), is, in our opinion, a too restricted and defeatist point of view. Episodes of increased crustal instability along one sector of a mobile belt may not produce equal, or indeed any, noticeable increase in the actual intensity of tectonic activity at given localities, but, when viewed as a whole, a pattern of contemporaneous rhythmic increase and decrease of tectonic/thermal activity within the belt may emerge, leading eventually to a widespread paroxysmal event, after which the activity of this particular mobile sector of the crust begins to wane.

RUBIDIUM/STRONTIUM AGES FROM THE WESTERN TRANSVAAL

By Dr. H. L. ALLSOPP

Bernard Price Institute of Geophysical Research, University of the Witwatersrand, Johannesburg

THE older granites and gneisses of the southern and western Transvaal, South Africa, are mainly covered by younger strata, but are exposed in six inliers some hundreds of square miles in extent. In some areas the granites intrude narrow 'Archean' schist belts; in the absence of other field relationships it has not hitherto been possible to demarcate granites of different ages, and the assemblage of granites and gneisses has been termed 'Basement Complex'.

The age of granites as determined by the rubidium/strontium method is critically dependent on the value taken for the primary $^{87}Sr/^{86}Sr$ ratio (R_i), particularly in the case of total-rock samples for which the present-day $^{87}Sr/^{86}Sr$ ratio (R_p) is usually less than about 0·9. In favourable circumstances R_i is determined from an isochron plot of a suite of total-rock samples, but other cases of geological interest occur for which this is not possible, for example, when only isolated borehole cores are available. For such cases R_i might be determined by the investigations of separated mineral fractions, but because of the possibility of misleading results following the re-homogenization of strontium isotopes on a mineral-to-mineral scale this was not attempted. Instead an assumed value of R_i is used, even though the uncertainty in the estimated R_i value is a limitation on the accuracy of the calculated ages. The first part of this article is concerned with the estimation of R_i; following this the ages of a number of isolated granite samples are calculated, and new upper limits are established for the ages of the Ventersdorp, Transvaal and Witwatersrand systems.

The granite which is exposed between Johannesburg and Pretoria was the subject of a previous article[1]; but the R_i value then obtained has since been revised by allowing for mass-spectrometer discrimination. Discrimination in solid-source mass-spectrometers was conclusively demonstrated by Hedge and Walthall[2], who showed that, although repeated measurements of the isotope ratios of a standard strontium sample on different instruments gave scattered results, the variations in the $^{87}Sr/^{86}Sr$ and the $^{88}Sr/^{86}Sr$ ratios were linearly related. An earlier investigation in this laboratory failed to show such a relationship, possibly because imperfect resolution of the strontium-87 isotope by our instruments caused undue scatter of the measurements. Because of this it was felt that the procedure of normalizing[3] all isotope ratios to conform with a particular $^{86}Sr/^{88}Sr$ ratio was not justified. This view is now reversed and all results in this article are normalized on the basis of a $^{86}Sr/^{88}Sr$ ratio of 0·1194. The improvement in the reproducibility of duplicate analyses so achieved is not very marked, possibly because of the imperfect resolution, and for the same reason a small systematic bias may still exist. However, the R_i values deduced here are directly applicable to measurements made on our instruments. The mean $^{86}Sr/^{88}Sr$ ratio as measured on our two single-filament 6-in. mass spectrometers is $0·1182 \pm 0·0002$, and the R_i ratio for the Johannesburg–Pretoria granite is simply reduced by half the ratio of 0·1194–0·1182. The new R_i value so obtained is $0·706 \pm 0·003$.

*OG*28*B**	41·38 ± 0·41	20·23 ± 0·20	2·021	0·786 ± 0·003

* In these cases only one measurement was made of the concentrations, and an uncertainty of 1 per cent is assumed. In all other cases errors quoted in this article are standard deviations of replicate measurements.

The data set out in Table 1 and Fig. 1 relate to a second granite exposure, sampled randomly over an area of approximately 100 square miles to the south-west of the village of Schweizer Reneke, which is some 200 miles south-west of Johannesburg. The geology of the area was described briefly by Jorissen[4], and in the main the granite is a homogeneous body of medium grain consisting chiefly of quartz, plagioclase, orthoclase, microcline and biotite. It intrudes a complex belt of schists in the west, and in the vicinity of the schist the granite is foliated and occasionally gneissic. Eight total-rock samples were analysed using the usual isotope-dilution techniques. Duplicate dissolutions were made on four of the samples, and on all solutions replicate spiked rubidium-, spiked

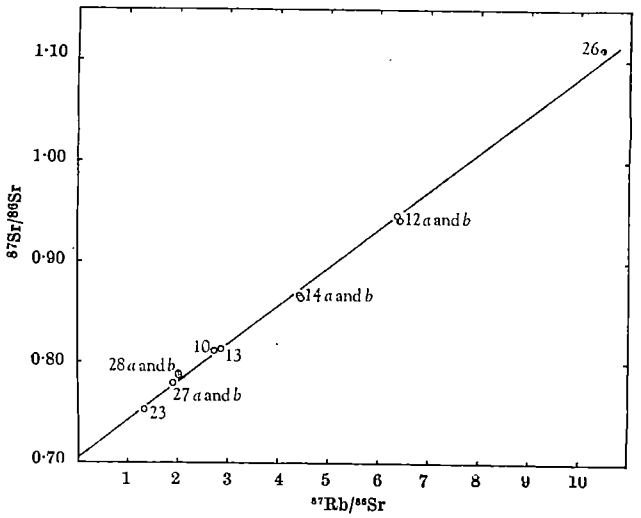

Fig. 1. The Schweizer Reneke isochron; $^{87}Sr/^{86}Sr$ plotted against $^{87}Rb/^{86}Sr$ for all the Schweizer Reneke total-rock samples

and unspiked strontium-aliquots were analysed. In the calculation of R_i and the age by the method of least squares the results of the duplicated dissolutions were treated as independent points, and the result obtained is:

$$\text{Age} = 2{,}700 \pm 55 \text{ m.y.}, \quad R_i = 0{\cdot}704 \pm 0{\cdot}004$$

A further value of R_i was deduced for a rock (*OG*19 from the farm Witklip, 6 miles south of Ventersdorp) from the same area as the samples discussed here. This granite has a very low rubidium/strontium ratio, and by using the measured R_p ratio of 0·718 and an assumed age of 2,700 m.y. (the calculation is relatively insensitive to this figure) a value of R_i of 0·706 ± 0·003 is obtained.

From the Ventersdorp–Klerksdorp area seven rocks of stratigraphic importance were investigated. Some of these were obtained from borehole cores, others from exposures of small expanse. In each case the age of a total-rock sample was calculated assuming $R_i = 0{\cdot}705 \pm 0{\cdot}002$ (the mean of the three values mentioned above) and the data are summarized in Table 2. In the majority of cases the ages agree within experimental error either with that of the Johannesburg–Pretoria granite (3,200 ± 65 m.y.) or with that of the Schweizer Reneke granite (2,700 ± 55 m.y.) and this indicates that there were two distinct periods of granite formation in this region.

Table 2. Ventersdorp-Klerksdorp Results

Sample	^{87}Rb (p.p.m.)	^{86}Sr (p.p.m.)	$^{87}Sr/^{86}Sr$ (atomic)	Age (m.y.)*

RSPIC	25·40 ± 0·20	9·029 ± 0·040	0·816 ± 0·002	2,820 ± 55

* Throughout this article $\lambda = 1{\cdot}39 \times 10^{-11}$ y.$^{-1}$

In the conventional isochron plot of Fig. 1 the Schweizer Reneke results are seen to approximate to a straight line, but the results of the duplicated dissolutions suggest that some points may differ significantly from the best-fitting line. Also some of the Ventersdorp–Klerksdorp results differ widely from the mean ages. These age variations may be genuine; but it is also possible that the samples in question have suffered chemical alteration (this is especially likely in the case of *RSPIC*, obtained only 3 in. beneath the Dominion Reef contact), or that there exist regional variations in R_i. The last-mentioned possibility is quite consistent with the modern view[5] that the basement granites in the Transvaal were formed, at least in part, by the remobilization of older material.

Ventersdorp rocks lie unconformably on the granite at Schweizer Reneke, at the site of *OG*18 and in the borehole *AN*954: the Ventersdorp and Transvaal systems are therefore younger than 2,700 ± 55 m.y. In borehole *AN*952 lower Witwatersrand rocks overlie granite with an age 2,720 ± 100 m.y. and this sets the same upper limit on the age of this system. Similarly, an upper limit of 2,820 ± 55 m.y. is set on the age of the Dominion Reef by the result on the granite from borehole *RSPIC*. The actual ages of the overlying strata mentioned may be considerably younger than the limits given, since a long period must have elapsed between the time of intrusion of the granites and the deposition of sediments on surfaces of the granite exposed by erosion.

The origin of the Witwatersrand gold and uranium deposits has been the subject of much controversy. The age of uranium-bearing minerals found in Dominion Reef sediments is 3,100 ± 100 m.y.[6]. Corresponding data for Witwatersand uraninites give an age of 2,040 ± 100 m.y.[7], but Burger *et al.*[8] observed that the galenas found in veins intruding the Witwatersrand system are enriched in radiogenic lead and reasoned that this came from 'parent uraninites' occurring nearby in the Witwatersrand conglomerates. Assuming that the uraninite age of 2,040 ± 100 m.y. dates the period of lead-loss, Burger *et al.* deduced that the age of the parent uraninite is 2,950 ± 100 m.y. The uranium-mineral ages are compared below with the upper limits given in this article for the ages of the Witwatersrand and Dominion Reef systems.

	Uranium-mineral ages (m.y.)	Limiting sediment ages (m.y.)
Witwatersrand	2,980 ± 100	2,720 ± 100
Dominion Reef	3,100 ± 100	2,820 ± 55

It is unfortunate that the uncertainty intervals attached to the mineral and sediment ages almost overlap; but in both cases the uranium-minerals appear to be older than the sediments in which they are found. This favours the theory of a detrital origin of the uranium and associated gold deposits. It is of interest to note that granites sufficiently old (~3,100 m.y.) to have provided the necessary detritus occur in both the Johannesburg area[1] and the Klerksdorp area (this article).

Samples *AN*952 and *AN*954 were supplied by Dr. Waters of Anglo-American Corporation and *RSPIC* by Dr. Wilson of General Mining and Finance Corporation. I thank Dr. W. Compston and Dr. L. O. Nicolaysen for their advice.

Appendix: Sample Locations

Except where otherwise specified, fresh samples were obtained from surface outcrops. A detailed account of this age survey will be published elsewhere, and will include petrographic descriptions of the samples referred to here.

*OG*10. On Schweizer Reneke townlands; 3 miles from the town along the main road to Vryburg.

*OG*12. On Farm Bellevue 117; 9 miles west of Schweizer Reneke, at level crossing on disused section of road to Amalia.

*OG*13. On farm Seringboomkop 66; outcrops occur to north of road leading from Schweizer Reneke to Amalia, and 7 miles from the former.

*OG*14. On Schweizer Reneke townlands and 2 miles west of it. Outcrops occur south of road to Amalia.

*OG*23. On southern extremity of farm Seringboomkop 66; half a mile south of road at a point 7 miles along road from Schweizer Reneke to Diewedraai.

*OG*26. On farm Delareyskraal 69; outcrops occur to south of road at a point 12 miles along road from Schweizer Reneke to Diewedraai.

*OG*27. On Schweizer Reneke townlands; 1·5 miles north from the junction of the Schweizer Reneke–Vryburg road with the road to Broedersput.

*OG*28. On farm Luciana 43; 3·75 miles south along farm road from its junction with the Schweizer Reneke–Vryburg road.

*OG*16. On farm Vaalbank 66; 3 miles east of Gerdau and approximately 20 miles north of Ottosdal. Outcrops occur close to homestead.

*OG*17. On farm Rhenosterberghoek 88; 3 miles south of Hartebeesfontein on road to Rhenosterspruit.

*OG*18. On farm Brakspruit 5; granite is exposed in dry pan 1·5 miles west of Klerksdorp–Ventersdorp road and approximately 8 miles north of Klerksdorp.

*OG*32. Sample collected at depth of approximately 1,000 ft. in the Rietkuil section of Afrikaner Leases Mine, 7 miles west of Klerksdorp.

RSPIC. Core of borehole situated near southern extremity of farm Rhenosterput 108, 8 miles north of Ottosdal. Sample depth 290 ft., 3 ft. below contact with Dominion Reef quartzites.

*AN*952. Core of borehole situated on farm Makokskraal, 10 miles west of Ventersdorp. Sample depth 10,417 ft., 22 ft. below contact with lower Witwatersrand beds.

*AN*954. Core of borehole situated on farm Ratzegaaiskraal, 6 miles west of Ventersdorp. Sample depth 1,741 ft., 55 ft. below contact with Ventersdorp lavas.

EUROPEAN MID-DEVONIAN CORRELATIONS

By PAUL COPPER

Department of Geology, Imperial College of Science and Technology, London, S.W.7

A GROUP of brachiopods belonging to the atrypid family Palaferellidae Spriestersbach[1] shows a pattern of muscle platform development which may be of value in the correlation of Middle Devonian sediments in the western hemisphere. A brief description of important features in this rapidly evolving phylogenetic lineage is given.

The family Palaferellidae at present contains only a single genus, *Gruenewaldtia* Chernychev, which is characterized by the presence, in both valves, of muscle platforms which are elevated from the shell floor by a variable number of septa. In a continuous, overlapping and intergrading, morphological series ranging in age from the lower Eifelian to upper Givetian (Middle Devonian), it can be shown that in the Palaferellidae muscle platforms initially were supported by numerous septa and that, with time, these septa decreased in number until support of the platform was reduced, in the case of the pedicle valve, to two septa. The final stage was reached when the platforms became solidly cemented to the shell floor and had only a brief anterior overhang. The end-product of this lineage, forms with cemented platforms, no longer fit categorically into the genus *Gruenewaldtia*, and a new genus, *Desatrypa*, is arbitrarily proposed for these. To avoid subsequent confusion it is described briefly:

'Order' Atrypida. Family Palaferellidae. *Desatrypa* n.gen.

Genotype species. *Atrypa desquamata* Sowerby 1840 (ref. 2), Pl. 56, Figs. 19–22.

Stratigraphic range. Upper Eifelian to upper Givetian, Middle Devonian.

Diagnosis. Biconvex to dorsi-biconvex atrypids with a prominent, wide inter-area and continuous, deep-troughed ribs interrupted marginally by weak, incipient concentric growth lamellæ. No frills or spines developed.

Internally, raised muscle platforms are cemented to the shell floor (a suture line may or may not be visible). Teeth are strong and lack lateral cavities. Massive hinge plates and thick cardinal blocks are typical. Crura are minute, vestigial and structurally different from those in normal atrypids. Some species completely lack dorsally directed spiralia. Deltidial plates are fused medially and are continuous with a pedicle collar or remnant pedicle collar (late Eifelian *Gruenewaldtia* also have monostructural deltidial plates and pedicle collars).

Member species. *Terebratula prisca* var. *flabellata* C. F. Roemer 1844 (ref. 3). *Terebratula insquamosa* Schnur 1853 (ref. 4).

A wide international distribution and long stratigraphic range have commonly been attributed to *Atrypa desqua-*

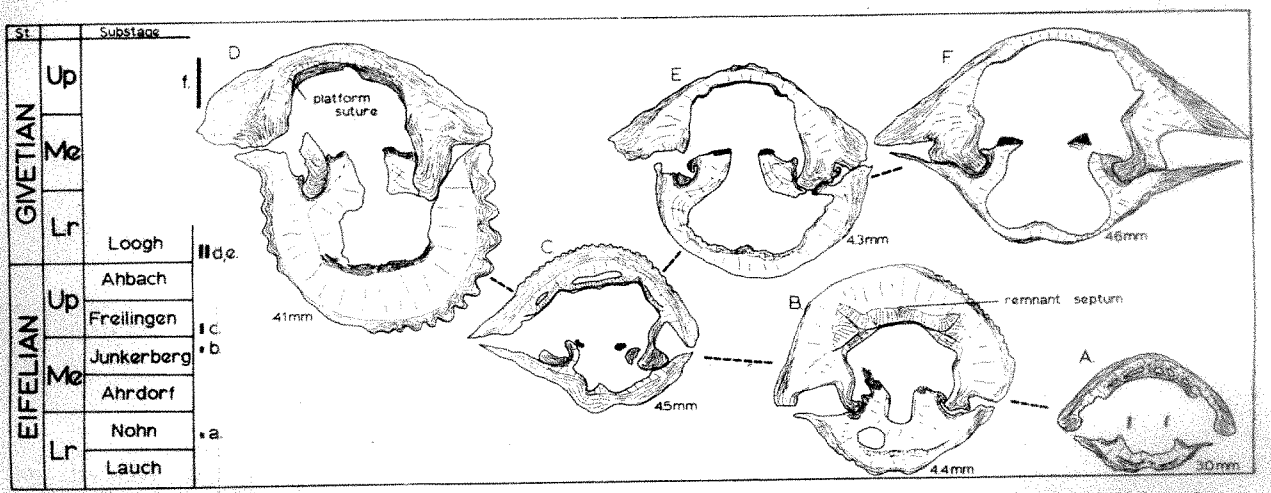

Fig. 1. Transverse sections of different palaferellid atrypids showing the septal development in the pedicle valve. All figures are half-size and are taken at the same stage of crural development. *A*, *Gruenewaldtia* sp. (non *G. rhenana* (Spriestersbach)) from the Schleit horizon, Nohn beds, lower Eifelian; *B*, *Gruenewaldtia latilinguis* (Schnur), upper Junkerberg beds, middle Eifelian; *C*, *Gruenewaldtia* sp. (non *G. apsaklina* Struve), Freilingen beds, upper Eifelian; *D*, *Desatrypta flabellata* (C. F. Roemer), lower Givetian; *E*, *Desatrypa insquamosa* (Schnur), lower Givetian; *F*, *Desatrypa desquamata* (Sowerby), upper Givetian. The transition between the two genera appears to have occurred about late Freilingen–early Ahbach time

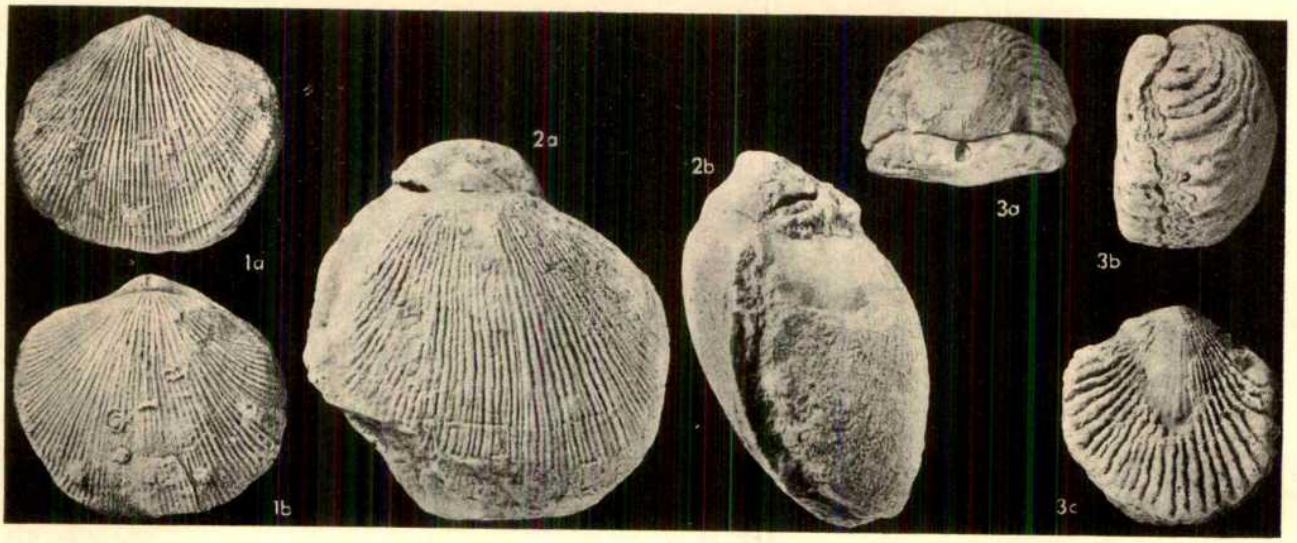

Fig. 2. 1*a* and *b*, *Desatrypa insquamosa* (Schnur), lectotype specimen from Schnur's original collection; 2*a* and *b*, *Desatrypa desquamata* (Sowerby), lectotype specimen, Sowerby collection; 3*a*, *b* and *c*, *Desatrypa flabellata* (C. F. Roemer), holotype, Roemer collection. All figures half size

mata Sowerby, the type species of the new genus *Desatrypa*. Most of the atrypids concealed under this name are, in fact, unrelated to the true *desquamata* of Sowerby, restricted to the upper Givetian. In 1960 Alekseeva[5] established the sub-genus *Desquamatia* and included in this sub-genus many species formerly called "*Atrypa desquamata*". As part of a monographic revision of west European atrypid faunas, I re-examined Sowerby's original material and sectioned topotype specimens of the species *desquamata*. It was then found that the internal structure of *Atrypa desquamata* Sowerby (family Palaferellidae) was very unlike that of the *Desquamatia* (family Atrypidae) described by Alekseeva, although externally they were in part strongly homœomorphic.

The stratigraphical and geographical distribution of the palaferellids is not fully known. Two geographically isolated stocks appear to have existed during late Eifelian–Givetian times. The first, a divergent stock leading to *Desatrypa*, is chiefly concentrated in western Europe and is known from England, France, Belgium and Germany, and probably occurs also in the Carnic Alps of Italy. A second, the root-stock *Gruenewaldtia*, appears to have persisted with little modification to the Upper Devonian at Ober-Kunzendorf near Wroclaw, Poland[6], and is known from the Givetian of the Kutznetsk basin in U.S.S.R.[7]. The emergence, during Givetian time, of massive stromatoporoid-crinoid reefs in north-western Europe coincided with the development of *Desatrypa* n. gen., which is largely restricted to such an environment. It is speculated that *Desatrypa* developed in response to this change in environment. Cementation (and hence strengthening) of the muscle platform probably was advantageous in the more turbid waters of the reefs.

PRE-PICKWELL DOWN AGE OF THE PLATEAU BEDS (UPPER DEVONIAN) IN SOUTH WALES

By J. R. L. ALLEN

Sedimentology Research Laboratory, Department of Geology, University of Reading

HISTORICAL. The Old Red Sandstone (Devonian) sequence in the Black Mountain, Fforest Fawr, and Brecon Beacons in Carmarthenshire and Brecknockshire comprises the Red Marls—Senni Beds—Brownstones—Plateau Beds—Grey Grits, in that ascending order. The age of the Plateau Beds has remained longest in doubt, and so far there have been several attempts to assess the stratigraphical position of this group. The group is important because of the decisive clues it affords as to the Middle and Upper Devonian history of South Wales.

The term 'plateau-beds' was first used by Strahan *et al.*[1] working in the Brecon Beacons area, for hard pebbly sandstones which gave table-like caps to mountains cut largely from Senni Beds and Brownstones. The plateau-beds were included in the Brownstones referred to the Lower Old Red Sandstone. The Grey Grits, shown to be of Upper Old Red Sandstone (Upper Devonian) age, were considered to overstep or overlap the plateau-beds westwards. Later, from work in the Black Mountain, Strahan *et al.*[2] stated that the Grey Grits overstepped the plateau-beds.

Robertson[3], in revising the account of the Brecon Beacons area, gave the group formational status, writing it as Plateau Beds. From the evidence of a new section in the Abercriban Grit Quarry, Pont-sticill, Brecon Beacons, he concluded that the Plateau Beds graduated up into the Grey Grits. It was suggested that if a stratigraphical break occurred in the Old Red Sandstone sequence above the base of the Brownstones, it could be represented by the coarse strata beginning the Plateau Beds. Such a break, he implied, would if proved probably equate with the Middle Old Red Sandstone unconformity known from the surrounding regions.

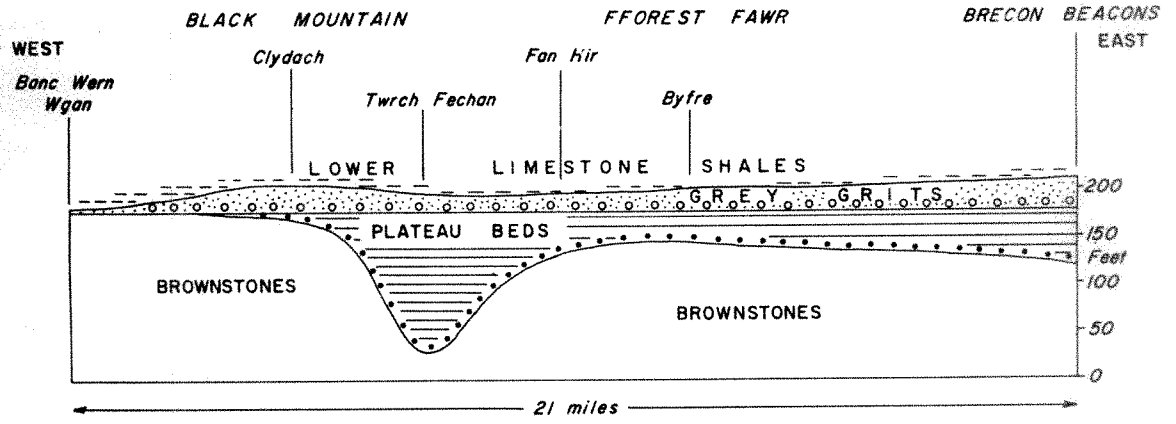

Fig. 1. Relationship of Plateau Beds to Grey Grits and Brownstones in Brecon Beacons, Fforest Fawr, and Black Mountain districts, South Wales

Later, a fauna was reported from the Plateau Beds by Pringle and George[4], Simpson[5] (who acknowledged its partial discovery by Dr. Gwyn Thomas), and Croft[6]. This included the marine brachiopod *Cyrtospirifer verneuili*, marine molluscs, and the vertebrates *Holoptychius*, *Bothriolepis*, and *Sauripterus*, establishing the Upper Devonian, and possibly Famennian, age of the Plateau Beds. Croft[6] also noted the occurrence of *Rhinopteraspis cornubica* (McCoy) in the Senni Beds, which thus emerge as Lower Old Red Sandstone (Lower Devonian) in age.

It would appear that Pringle and George[4] regarded the Old Red Sandstone sequence in the Brecon Beacons area as substantially complete, with the Lower, Middle, and Upper divisions all represented in the sequence Brownstones through to Plateau Beds.

Simpson[5,7] correlated the marine Plateau Beds with the marine strata of late Famennian age at the top of and immediately overlying the Skrinkle Sandstones in Pembrokeshire[8]. This allowed him to postulate a single, "Strunian" marine transgression across South Wales, and he remarked[5] that the first general break in deposition in the region since the close of the Silurian was in the Dinantian (Lower Carboniferous).

Summarizing the position, while the Plateau Beds are established on faunal evidence as Upper Devonian, there is confusion in the literature regarding their relationship to the Brownstones beneath and the Grey Grits above. So far the Plateau Beds have been correlated with the Skrinkle Sandstones of Pembrokeshire.

Stratigraphical breaks. The Upper Old Red Sandstone in Carmarthenshire and Brecknockshire is marked by two stratigraphical breaks: at the very base beneath the Plateau Beds, and higher up between the Plateau Beds and the Grey Grits. Both breaks record erosion after uplift as will be shown, but in terms of angular discordance each is probably a disconformity rather than an unconformity.

Robertson[3] considered the pebbly rocks beginning the Plateau Beds as possibly indicating a break in the Old Red Sandstone. As can be observed repeatedly in the field (for example, National Grid Ref. Nos. *SN* 823180, 742189), a marked change in lithology certainly occurs at this level, for the alternating red siltstones and reddish-brown fine sandstones of the Brownstones are abruptly and erosively overlain by pebbly sandstones or sandy conglomerates of a different shade of red. Since the Plateau Beds yield Upper Devonian faunas, and the Senni Beds a Lower Devonian vertebrate, such a break could mean the absence of a good deal, if not all, of the Middle Devonian.

That an angular discordance between the Plateau Beds and the Brownstones accompanies the lithological break noted can also be seen on the ground, and this important fact was first observed by Dr. Gwyn Thomas many years ago. Plateau Beds above Brownstones are exposed on an inaccessible rock-wall stretching for nearly two miles from Fan Hir (*SN* 833195) to Fan Foel (*SN* 821225) in the Black Mountain. The pebbly sandstones commencing the Plateau Beds form a long, unbroken crag. Sandstones in the Brownstones form less conspicuous crags supporting grassy ledges hiding siltstone ribs. From hills to the east the impression is gained that the Plateau Beds overlie the bevelled edges of sandstones making up the Brownstones. This impression is strikingly confirmed in fore-shortened views of the rock-wall obtainable from the hill-shoulder north-west of Blaen Car (*SN* 835194). The base of the Plateau Beds, tilted gently south, can be seen to transgress sandstone after sandstone in the Brownstones inclined southward a little more steeply.

Evidence for a stratigraphical break below the Grey Grits though not as striking is no less clear, and Strahan *et al.*[2] concluded that in the Black Mountain the Grey Grits overstepped the Plateau Beds westwards. Robertson[3], impressed by the supposed transition from the Brownstones (on his usage with Plateau Beds at the top) to the Grey Grits in the Abercriban Grit Quarry, thought overlap as likely. However, the supposed passage here is found to be illusory.

From the Brecon Beacons to the Black Mountain the Plateau Beds vary irregularly in thickness below the Grey Grits (Fig. 1), pinching out in the extreme west but maintaining over 18 miles a fairly constant development of pebbly rocks at the base. The lithological change from the one formation to the other is even more marked than that from the Brownstones to the Plateau Beds. In the Brecon Beacons and Fforest Fawr the uppermost Plateau Beds are red, fine-grained, silty sandstones and sandy siltstones with much flat- and ripple-bedding. The Grey Grits, in contrast, are pale, medium-grained, clean, pebbly sandstones or sandy conglomerates with a different suite of sedimentary structures. The contact of the two in the Twrch Fechan (*SN* 785208) is sharp, erosional, and without a trace of a passage. A similar contact is found in the Clydach (*SN* 742185), where pebbly, medium sandstones of the basal Plateau Beds lie beneath white conglomerates of the Grey Grits. Further west still undoubted Brownstones occur immediately beneath the Grey Grits. No trace of passage can be found between the Plateau Beds and Grey Grits, and despite the apparent conformity of bedding the field evidence definitely supports Strahan's[2] assertion of overstep by the Grey Grits.

Sedimentological evidence of age. As Strahan *et al.*[2] and Robertson[3] showed, the Grey Grits in the Fforest Fawr and adjoining areas graduate up into the Tournasian Lower Limestone Shales.

The Grey Grits in the same area show a continental facies, closely resembling modern stream channel deposits in grading and sedimentary structures. A similar con-

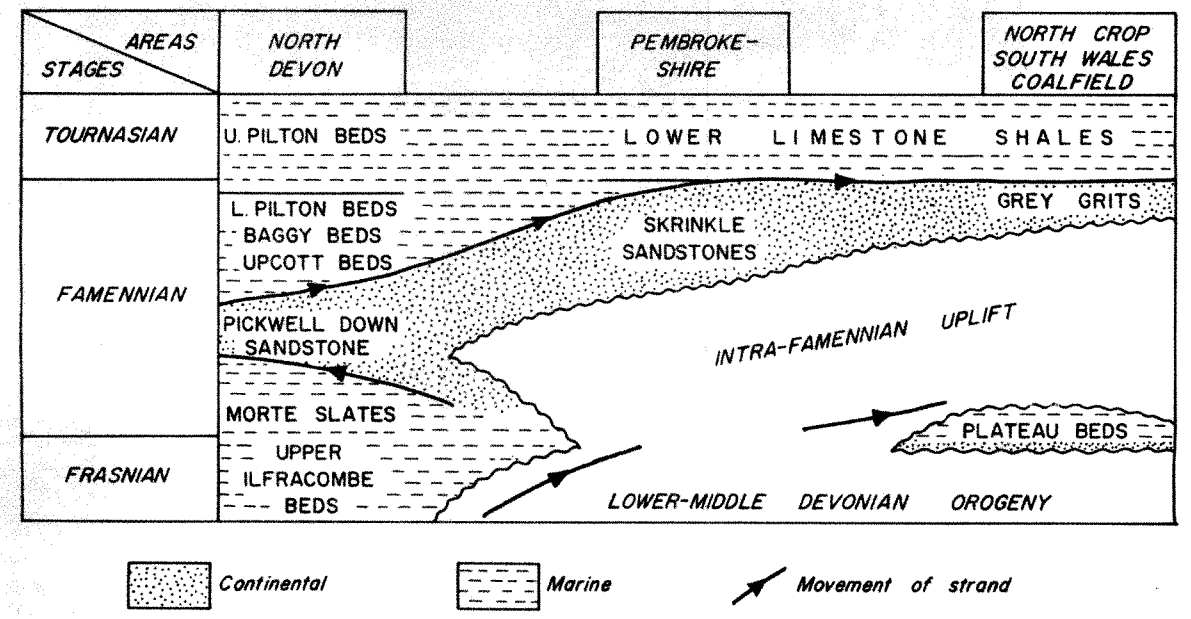

Fig. 2. Upper Devonian correlations in North Devon, Pembrokeshire, and the North Crop of the South Wales Coalfield, to show the probable position of the Plateau Beds

tinental facies—abounding in suncracks, ripple marks, and cross-bedding, and therefore also probably fluviatile—is represented in Pembrokeshire by the Skrinkle Sandstones lying conformably beneath the Lower Limestone Shales[8]. The Skrinkle Sandstones disconformably succeed the Ridgeway Conglomerates and Red Marls. Although because of Lower Carboniferous overlap a connexion between the two areas is not now visible, the Grey Grits and Skrinkle Sandstone must in part be of the same age. Not only do they agree in facies, pointing to an origin during the same depositional episode, but also both pass up into the Lower Limestone Shales.

The largely marine Plateau Beds, separated from the Grey Grits by a disconformity, therefore probably record an event previous to the deposition of the Skrinkle Sandstones. Simpson's[7] inclusion of the Plateau Beds in the same "Strunian" (that is, late Famennian) transgression as the marine, upper portion of the Skrinkle Sandstones[8] is not on these grounds acceptable. The evidence points to there having been two separate transgressions of the South Wales area during Upper Devonian times.

The age of the earlier Plateau Beds transgression hinges largely on a reading of the Upper Devonian sequence in South Wales and North Devon, particularly with regard to the succession and nature of events (Fig. 2). No decisive clue as to age is given by the Plateau Beds fauna, which is certainly Upper Devonian, but not so certainly Famennian.

In South Wales the angular discordance between the Plateau Beds and the Brownstones, and between the Skrinkle Sandstones and Ridgeway Conglomerates or Red Marls, manifests the Lower to Middle Devonian orogeny which strongly affected the more northerly parts of Wales[9]; and the Plateau Beds themselves a northward marine transgression from the Devonian trough in Cornubia. Southward retreat of the shore and uplift followed by erosion is implied by the relationship of the Grey Grits and Skrinkle Sandstones to the Ridgeway Conglomerates, Red Marls, Brownstones, and Plateau Beds. A later marine transgression, oldest in the south and west, is proved by the uppermost Skrinkle Sandstones and the Lower Limestone Shales.

In North Devon the Upper Devonian correlations shown in Fig. 2 are those of Goldring[10]. The Upper Ilfracombe Beds and the Morte Slates with *Cyrtospirifer verneuili* are marine, and a southward retreat of the strand is shown by their transition into the Pickwell Down Sandstone. This is of continental facies, possibly fluviatile, consisting largely of red and grey cross-bedded sandstones. The only fauna is of vertebrates reported as *Holonema*, *Bothriolepis*, *Holoptychius*, and *Polyplocodus*[11]. Following Goldring[10], "the succeeding strata tell an intriguing story of a deepening sea, harmonizing with the marine transgression to the north over the Old Red Sandstone continent".

In South Wales and North Devon, on the northern margin of the Cornubian trough, the sequence of environments represented in the Upper Devonian and earliest Lower Carboniferous strata is from shallow-marine through to continental reverting to shallow-marine. Correlating rocks of like environment to afford a rational picture of events, the Plateau Beds emerge as probably earlier than the Pickwell Down Sandstone, and such a correlation is not inconsistent with the faunas so far obtained from the Plateau Beds and Morte Slates. The Plateau Beds may therefore prove to be of late Frasnian or early Famennian age (Fig. 2).

The pre-Pickwell Down transgression may have entered areas other than South Wales, since at Wyboston, Bedfordshire, a sequence analogous to that of the Plateau Beds and Grey Grits was proved by boring. Upper Old Red Sandstone is reported to overlie marine Upper Devonian rocks unconformable on the Cambrian[12].

ASTROPHYSICS

Lithium in Capella and Convective Mixing in *F* and *G* Giants

On two spectrograms of α Aurigæ taken on August 25 and 26, 1964 (U.T.), we have found that the lithium line at λ6707·8 is much stronger in the *F*8 star than in the *G*5 component. Henceforth we will refer to the two components as Capella *F* and Capella *G*. One of the spectra is shown in Fig. 1, where lines of both components have been identified. A density tracing is shown in Fig. 2. In this communication we will first present evidence to show that our identification is correct and will derive rough abundances of lithium in the two stars. We will then discuss the implications of this difference with reference to stellar structure and evolution.

According to the orbit of Struve and Kilby[1] and of Wright[2] the radial velocity of Capella *F* was +55 km/sec and that of Capella *G* was +4 km/sec at the time of the observations. Our measurements of the broad feature yield a velocity of +59 km/sec if it is to be identified with λ6707·81 of lithium-7. If it were contributed by the *G* star, the laboratory wave-length would be λ6709·5, at which point we find no reasonable identification. Secondly, the width of the line matches the widths of the *F* star's lines rather than those of any single line in the *G* star[3].

Next we estimate the abundance of lithium in each star. The measured equivalent width of the lithium line contributed by the *F* star is 80 mÅ. Correcting for the fact that the *F* star contributes only 40 per cent of the light at λ6700, the true equivalent width is about 200 mÅ. If the star has the same effective temperature as the Sun, the lithium abundance is at least 100 times the solar lithium content. The exact value depends on the microturbulence and ratio of lithium-6/lithium-7, neither of which can be determined when the lines are broadened by the 10–12 km/sec rotation of Capella *F*. There is no lithium line in the *G* star. The feature shown in Figs. 1 and 2 is the unidentified line which appears in the Sun at λ6707·52. However, it provides a good limit on the minimum visibility of lines so as to estimate the upper limit of the lithium abundance in Capella *G*. We find its equivalent width to be 12 mÅ which is converted to 20 mÅ when account is taken of the fact that the *G* star contributes 60 per cent of the light. Using this as the upper limit on the equivalent width of the lithium line and using Bonsack's data for *G*8 giants[4], we find an upper limit on the lithium content in Capella *F* that is equal to the solar abundance.

We now ask why these two stars separated by about one astronomical unit should differ in their lithium content by a factor of more than a hundred. First, we point out two simple and probably incorrect explanations. The two stars could have formed from material of drastically

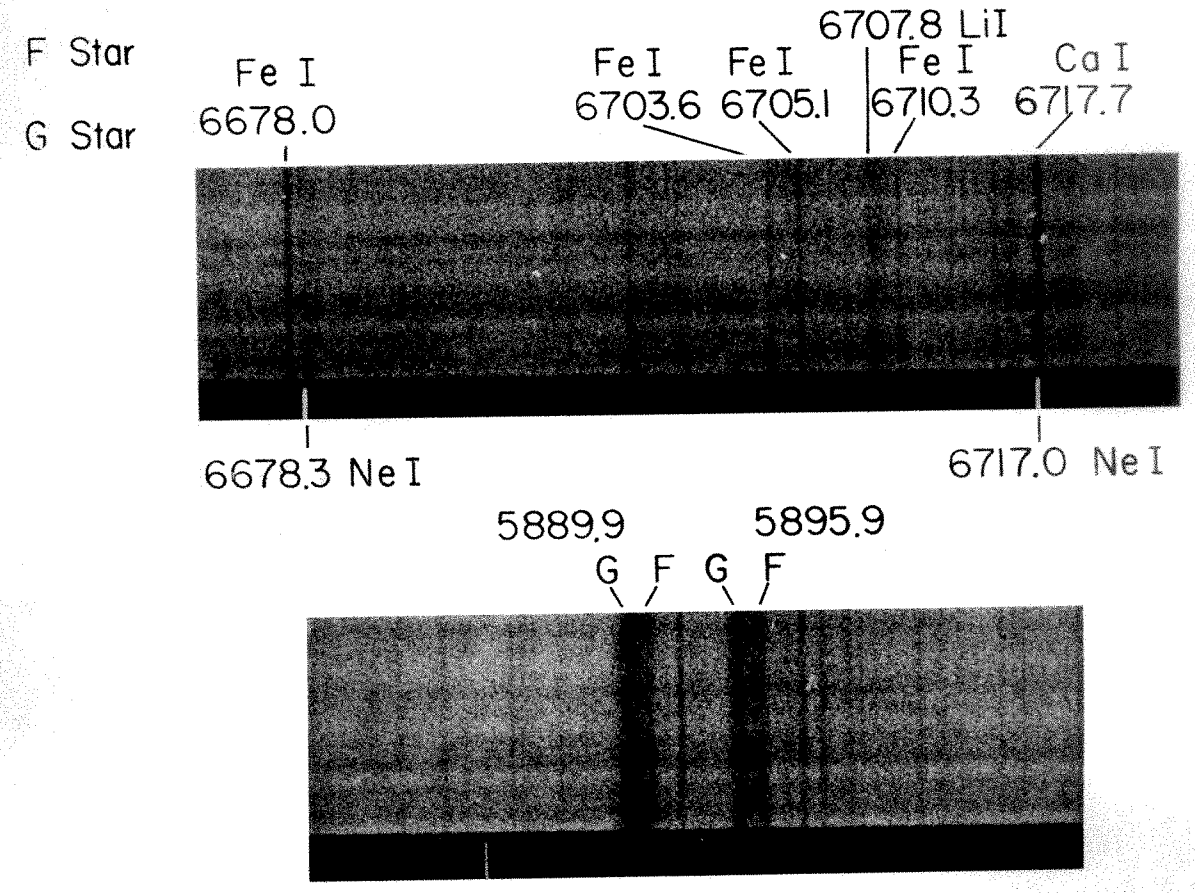

Fig. 1. The spectrum of α Aurigæ at the lithium line and the sodium *D* lines. Wave-lengths and identifications for lines contributed by both the *F* and *G* stars are shown. Two neon comparison lines are also shown in the upper spectrum

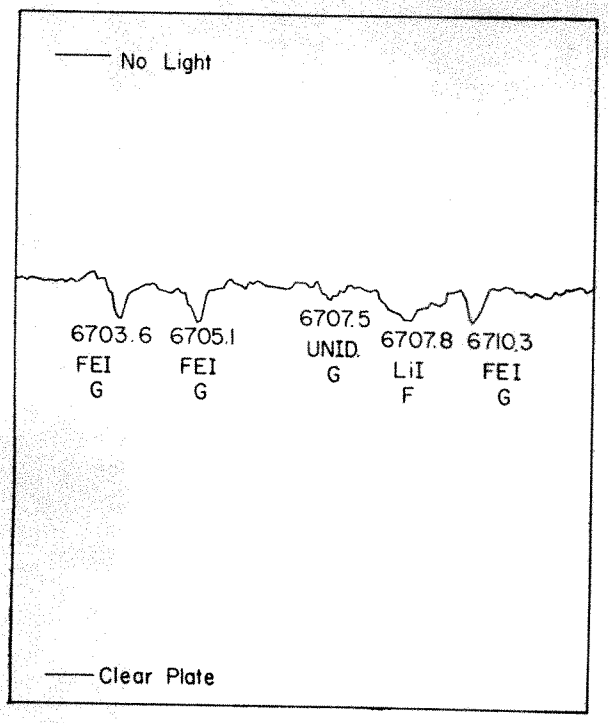

Fig. 2. A density tracing of the region near the lithium line

different chemical composition, or they could have produced different amounts of lithium on their surfaces by spallation reactions. It is difficult to imagine that two stars as close as the Capella pair could have originated from substantially different material. In such binary systems as have been examined, for example, γ Leo[5], 16 Cyg[6] as well as 3 *G* dwarfs and 4 yellow giants in the Hyades[7,8], no differences in chemical composition have been found. Differences in surface production (if that is indeed where the lithium was made) are more difficult to rule out, but we note that for 18 main sequence Hyades stars between types *F*0 and *G*0 the ratio of the greatest to the least lithium abundance is a factor of 6, some (but not all) of which may be accounted for as observational scatter[9].

Table 1

	Capella *G*	Capella *F*
Mass	3·03⊙	2·91⊙
Mv	0·12	0·37
Spectral type	*G*5 III	*F*8-*G*0 III
T_{eff}	4,650–5,000° K	5,300–5,800° K
Radius	14·1–12·2⊙	8·9–7·5⊙

If we are willing to accept that the two components of Capella had about the same lithium content when they were main sequence stars, then we are forced to the conclusion that Capella *G* has destroyed 99 per cent of its original lithium. We suggest that it has done so by convective mixing to regions at which the temperature is sufficiently high (2–3 × 10^6 °K) for the reaction $Li^7(p,\alpha)He^4$. The high lithium content of the main sequence stars in the Hyades[9] and the low lithium abundances in the Hyades *K* giants[4] indicate that a similar effect has occurred there. Thus we suggest that the two stars of Capella can be used as a test of the theories of stellar structure and especially of the theory of convection. The masses and absolute magnitudes are well determined but the effective temperatures are somewhat uncertain because of the uncertainty of the spectral types, especially of the secondary, and the calibration of the spectral type versus effective temperature relations[2,3,10]. The basic data for Capella *F* and *G*, taken largely from Wright's analysis[2], are presented in Table 1.

RADIOPHYSICS

Signal Strength Variations of Satellite Signals

Recordings of the strength of the 54-Mc/s radio beacon transmission from the satellite 1961 o1, *Transit* 4*A*, have been made at Moore's Valley, Wellington, New Zealand (41° 17′ S., 174° 47′ E.), and at Campbell Island (52° 30′ S., 169° 0′ E.). The signals received on a horizontal half-wave dipole have often been seen to exhibit a quasi-periodic type of fading. This is in addition to the Faraday and scintillation effects normally observed.

The result of an analysis of this fading during seventeen daytime passes recorded at Moore's Valley in April–May 1964 is shown in Fig. 1. Only the near-overhead south-west to north-east passes received during this period have been used, as they give the most consistent recordings of the phenomenon.

The satellite radio signal does not rise appreciably above noise until the satellite zenith angle approaches 70°. At this point the signal suffers large sinusoidal variations in strength at a rate of about 1 cycle in 10 sec. This rate increases steadily as the satellite rises, and reaches a maximum rate of some 2 c/s about 1 min after the satellite crosses the zenith. At this point the amplitude of the fluctuations may be less than 5 per cent of the total signal. Then the rate falls as the satellite progresses northwards, in much the same way as it rose in the south. At Wellington the ray path to the satellite is almost parallel to the Earth's magnetic field lines at the time of maximum fading rate. This may indicate a dependence of the phenomenon on the field direction as well as on the satellite position relative to the observer.

Other variations of the effect are seen in some records, such as two components an octave apart, or two com-

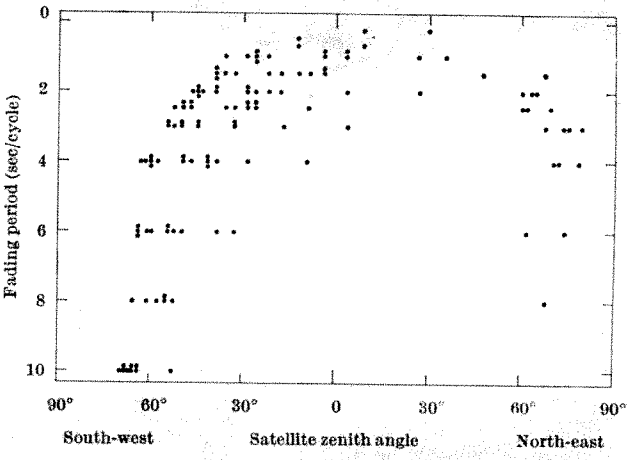

Fig. 1. Signal amplitude fading, 54 Mc/s for daytime overhead passes of Satellite *Transit* 4*A* observed at Moore's Valley, New Zealand, April–May 1964

ponents so close together in rate that beats are observed. There may be 1 beat in 20 sec between two components which have periods of some 2 sec.

The phenomenon is clearly distinguishable from the Faraday effect fading of some 40 sec period which is always seen. It also differs from the random period amplitude fluctuation or scintillation present in some records. This scintillation, with a mean period near 1 sec, is caused by modulation of the phase of the radio waves by irregularities in the ionosphere.

The frequency of the received signal is doppler-shifted due to the motion of the satellite; when it is first received it is about 1,200 c/s higher than the transmitted signal. It is observed to be falling at about 1 c/s/s; when the satellite crosses the zenith the rate of change of frequency is near 10 c/s/s, and for an instant the received frequency equals the transmitted frequency. The rate of change of frequency then decreases as the satellite recedes northwards from the zenith.

The variation with zenith angle of rate of signal fading may appear to be of similar form to the variation with zenith angle of the rate of change of frequency of the received 54 Mc/s wave, but there is no apparent reason for any causative relationship.

The results of a more detailed analysis of this type of quasi-periodic fading, using data from a comprehensive series of observations now in progress, will be reported at a later date.

I thank the Radiophysics Laboratory staff and the Campbell Island observer, Mr. N. McDonald, for their assistance.

GEOPHYSICS

Palæomagnetic Data and du Toit's Reconstruction of Gondwanaland

In a recent article[1], I demonstrated how palæomagnetic data for South America, Africa, Australia, Europe and North America can be used to reconstruct the positions of these continents in the Palæozoic. Although there are no palæomagnetic data for Palæozoic rocks of India or Antarctica we can investigate whether Mesozoic poles for these continents, listed in Tables 1 and 2, are consistent with du Toit's reconstruction. So far as North America, South America, Europe and Africa are concerned, this is similar to that deduced from the palæomagnetic evidence.

The poles for India and Antarctica were plotted on the 50-cm globe[1] and then traced on to a transparent shell on which the continents had been reassembled as described by du Toit[2]. The polar wandering curves are shown in the oblique azimuthal projection in Fig. 1, of which the pole of the latitude–longitude grid is the point where the Australian, South American and African polar wandering curves separate in the Permo-Triassic (Fig. 2). In Fig. 2, on a similar projection, are drawn du Toit's Gondwanaland and the polar wandering curves for: (1) South America; (2) Africa; (3) Australia; (4) Europe and western Russia; (5) North America; (6) India and (7) Antarctica. The curve for the first 5 continents is the one previously described[1].

Table 1. Palæomagnetic Poles for India

Formation	Place	Pole position Lat.	Long.	Ref.
Rajmahal traps (Jurassic)	Rajmahal	15° S.	112° E.	3
Deccan traps (Cretaceous-Eocene)	Linga	37° S.	97° E.	4
	Khandala	25° S.	101° E.	4
	Nipani (Lr)	35° S.	85° E.	4
	Amba (Lr)	22° S.	103° E.	4
	Nipani (Ur)	52° S.	110° E.	4
	Amba (Ur)	52° S.	116° E.	4
	Pavagadh (Lr)	58° S.	89° E.	4
	Pavagadh (Ur)	75° S.	91° E.	4

Table 2. Palæomagnetic Poles for Antarctica

Formation	Locality	Pole position Lat.	Long.	Mean
Jurassic dolerite intrusions	Ferrar Glacier	58° S.	142° W.	55° S. 136° W.
	Wright Mts.	51° S.	132° W.	
	Theron Mts.	54° S.	136° W.	
Andean intrusive suite	Grahamland	86° S.	2° W.	89° S. 100° E.
Tertiary lavas enozoic volcanics	South Shetland Is.	82° S.	129° W.	
	Cape Hallett	81° S.	94° E.	

Taken from ref. 5.

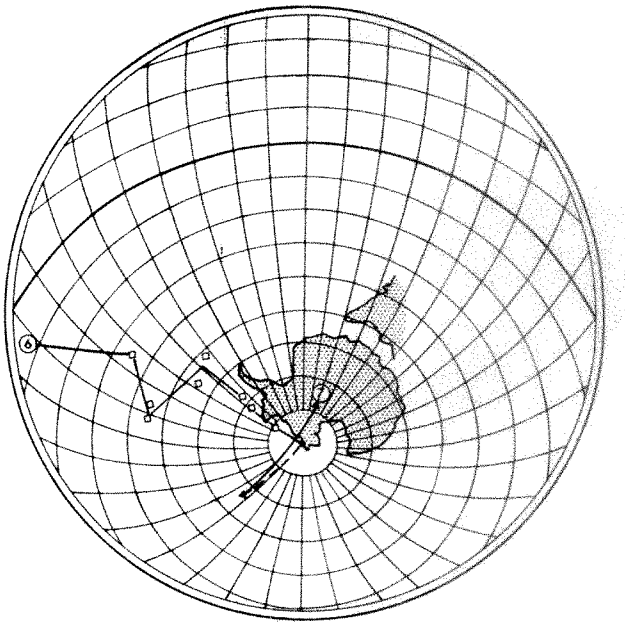

Fig. 1

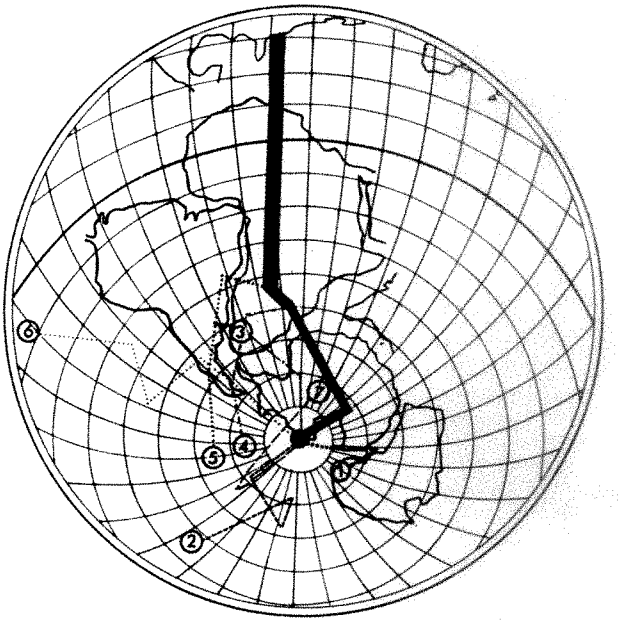

Fig. 2

With the continents so re-assembled we find that (i) the Indian polar wandering curve diverges from the Permo-Triassic point of the South American, African and Australian curves; (ii) the Jurassic pole for Antarctica is close to the Triassic pole on the African curve as though Antarctica and Africa remained together for a short while after South America and Australia had broken away.

One is led to predict that the Triassic pole for Antarctica will lie somewhere along the African curve between the pole of the projection of Fig. 2 and the Antarctic Jurassic pole; (iii) the Triassic poles for Australia and Africa do not coincide—hence these continents must have started to drift apart before the Triassic. There are no Triassic data yet for South America, India or Antarctica; (iv) the positions of all 5 Jurassic poles differ significantly from one another. Hence all five Gondwanic continents had started drifting by then; (v) the positions of the Permian poles for South America, Africa and Australia are not significantly different. There are no Permian data for India or Antarctica. The palæomagnetic data at present available are thus consistent with Gondwanaland having existed in the Permian.

Thus it appears that the Gondwanic continents started to drift apart in the Permo-Triassic. To elucidate in more detail how Gondwanaland broke up we shall have to wait for more comprehensive palæomagnetic data for the Mesozoic. Although those at present available for Australia[6] and Africa[7] are probably adequate, much more data are required for South America, Antarctica and India.

Computation of Liquidus Relationships in Multicomponent Silicate Systems

In a paper to be published elsewhere[1], algorithms and *Fortran II* programmes for computing liquidus temperatures and compositions in multicomponent ionic salt systems are discussed in some detail. The following is a preliminary report to the effect that simplified analogous programmes can be used for computing liquidus relationships in multicomponent silicate systems.

The present purpose is entirely practical, the goal being a system of available computer programmes for approximating liquidus relationships in complex systems when data for all the binary constituent systems are known.

We start with the ideal melting function:

$$\ln C = Q(1/T_m - 1/T)$$

in which T is a temperature (° K) on the liquidus of a component whose temperature of melting is T_m and heat of melting is Q, and C is its concentration in the liquid phase. A number of simplifying assumptions are made and the errors due to these and various kinds of non-ideality expected in silicate liquids are accumulated into a second-order polynomial expression for Q. Since it is difficult to retain conventions of molecular or ionic species in systems that involve phases with framework structures, C can be expressed in relative weight, instead of molar, units. Thus we select the following as empirical melting function:

$$\ln x = [a + b(1 - x) + c(1 - x)^2]\,[1/T_m - 1/T]$$

in which x is the weight fraction of a component in the liquid phase (at equilibrium with a crystalline phase in which x is the major component) and the parameters (a, b, c) are constants computed from experimental data on a specific binary system. For higher order systems, we compute the liquidus function of the ith component as follows:

$$\ln x_i = q_i[1/(T_m)_i - 1/T]$$

where:

$$q_i = 1 \Big/ \sum_{\substack{k=1 \\ k \neq i}}^{n} [g_k/(a_{i,k} + b_{i,k}h_k + c_{i,k}h^2_k)]$$

in which $(i = 1, n)$ is the index number of the principal component in the system, $(k = 1, n)$ is the index number of the additive components, $a_{i,k}$, $b_{i,k}$, $c_{i,k}$ are the individual parameters for best fit to liquidus data on the constituent binary systems,

$$g_k = x_k/(1 - x_i)$$

and

$$h_k = g^v_k(1 - x_i) + (1 - g^v_k)x_k$$

The exponent (v) of the weighting constant is included to allow arbitrary non-linearity of combination of the slope expressions: as v approaches zero, each unweighed slope expression approaches the form

$$a_{i,k} + b_{i,k}(1 - x_i) + c_{i,k}(1 - x_i)^2$$

and as v approaches infinity each approaches the form

$$a_{i,k} + b_{i,k}x_k + c_{i,k}x^2_k$$

Results of preliminary testing on data of real silicate systems do not indicate that the best value of v is not 1·0.

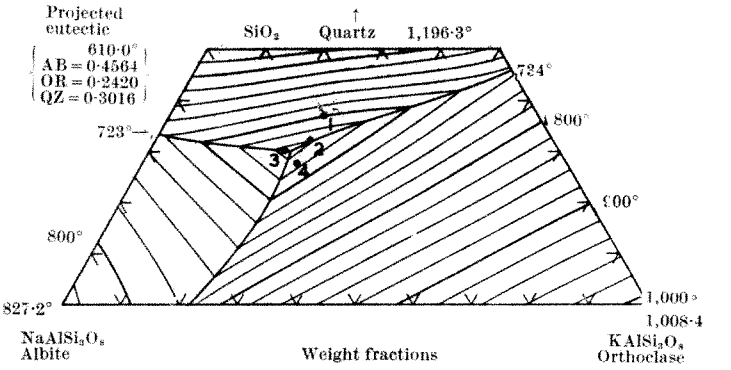

Fig. 2. System albite–orthoclase–quartz–water: projected isothermal curves on liquidus surfaces, derived graphically from points computed for constant water concentration, 0·0967, and constant pressure, 4,000 kg/cm². The numbered points represent published[2] experimental data for these conditions: (1) quartz liquidus at 705 ± 5°; (2) quartz or feldspar liquidus above 660°; (3) feldspar liquidus above 650°; (4) feldspar liquidus above 650°; eutectic below but near 650°. The liquidus surfaces of albite and orthoclase probably are continuous in part, but no estimate of this is shown

Another term which can be added to the net slope expression is one to allow for heat of mixing of components beyond the second:

$$\left(\sum_{k=1}^{n} x_k \ln x_k\right)\left((n-2)/n\right) \cdot T \cdot s$$

where T is the liquidus temperature and s is an arbitrary constant. Preliminary tests do not indicate that the best value of s is not zero.

Points of intersection of liquidus surfaces can be computed by a relatively simple iteration method given in more detail in the earlier paper. Programmes in *Fortran II* language have been written for computing and projecting liquidus points radially from all compositional vertices to one of the three-component planes. Thus the effect of components D, E, F, etc., on the temperature and composition of the eutectic between A, B and C can be investigated. Some of these programmes include the option of computing the temperature at 55 regularly-spaced compositional points on the liquidus of A, B and C at fixed composition of other components.

An example of the results of computations based on the foregoing method is the set of isobaric isotherms on the liquidus surfaces of the ternary system albite ($NaAlSi_3O_8$) –orthoclase ($KAlSi_3O_8$)–tridymite (SiO_2) (Fig. 1).

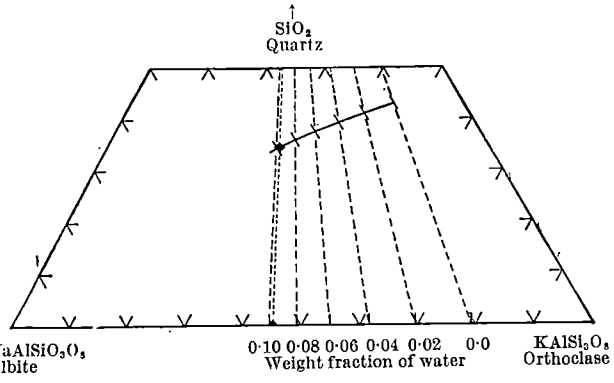

Fig. 3. System albite–orthoclase–quartz–anorthite–enstatite–Fe-pyroxene –Mn-pyroxene–alumina–magnetite–ilmenite–apatite–water: computed projected cotectic composition of the first three components at the indicated weight fractions of water, all other components being constant at normative values calculated from Daly's average composition of granite[3]; also a further projection of the computed cotectic points to the albite–orthoclase join. The normative composition of average granite projected in analogous manner (filled circle) lies very nearly on the curve of the computed cotectic points, and at 0·0970 water

An analogous example in the four-component system albite–orthoclase–quartz–water at a constant-weight fraction of water is shown in Fig. 2.

An example in a 12-component system, albite–orthoclase – quartz – anorthite – enstatite – ferro-pyroxene – mangano-pyroxene – corundum – magnetite – ilmenite – apatite–water, is shown in Fig. 3. In this, the components other than the first three and water were kept constant at values corresponding to those of the normative composition of average granite[3] and the cotectic composition with regard to the first three components was computed at six integral values of water concentration. The figure also shows the normative composition of average granite projected to the same plane. These results constitute a refinement of previous graphical approximation[4].

PHYSICS

Influence of Structure on Mechanical Properties of Pyrolytic Carbon

Previous work on the mechanical properties of pyrolytic carbon has been confined to massive deposits laid down on stationary formers[1,2]. Such deposits have a limited range of structure. An alternative preparation technique, developed primarily for coating nuclear fuel particles, involves the use of a fluidized bed[3]. Recent work on pyrolytic carbon deposited in a fluidized bed at 1,200°–2,100° C has shown that a very wide range of structures can be prepared by varying the deposition conditions. In general, these deposits are structurally different from massive deposits. The purpose of this communication is to demonstrate how the mechanical properties of pyrolytic carbon deposited in a fluidized bed depend on its structure.

Five different structures were obtained in a 2·5-cm-diam. coater with a 15-g charge of spherical uranium dicarbide particles 150–250μ in diam. The total bed surface area was 400 cm². The gas composition was 11 per cent methane in helium (total pressure = 1 atm), and the bed temperatures were varied from 1,350° to 1,925° C. The average time spent in the bed by the fluidizing gas was about 0·1 sec. The mechanical property specimens were obtained from 100 to 150μ pyrolytic-carbon layers deposited on graphite disks 1/4 in. in diameter introduced into the fluidized bed together with the particle charge.

The structures of the deposits were characterized by measuring the apparent crystallite size, L_c, the density and the preferred orientation. L_c was calculated from the formula[4]:

$$L_c = \frac{0{\cdot}89\,\lambda}{\beta\cos\theta}$$

where λ is the wave-length of the radiation used, β is the half-height width of the (002) peak, and θ is the Bragg angle for the (002) reflexion. The preferred orientation was measured by the Bacon technique[5] and characterized by Bacon's 'anisotropy factor', which is the calculated ratio of thermal expansion coefficients in the parallel and transverse directions at 400° C. Room-temperature, 3-point bending tests on specimens 6 mm × 1 mm × 0·1 mm were used to determine the flexural Young's modulus and the maximum fibre stress and strain at fracture. Deformation was elastic to fracture, and the results are presented in Fig. 1.

There is a remarkable decrease in modulus as deposition temperature is increased. Part of this decrease may be explained by the change in anisotropy. The effect of anisotropy on the modulus was estimated by using the preferred orientation curves in conjunction with the 'Reuss averaging' approach[6]. Elastic constants for graphite crystals[7] were used. Details of the calculation will be published. In general, for anisotropic solids, the flexural modulus is not identical with Young's modulus, but in the present case the anisotropy of the material is too small for the discrepancy to be important. The calculated modulus values are shown in Fig. 1c. It is evident that the change in modulus with deposition temperature is only partially explained by the change in anisotropy, and the bulk of the change is due to other causes. Some preliminary annealing experiments on a 1,350° C deposit obtained in the same coater with a carrier gas containing 40 per cent methane have shown that the modulus can be reduced from $5{\cdot}1 \times 10^6$ to $2{\cdot}2 \times 10^6$ lb./in.² by annealing at 2,300° C for four hours. The annealing treatment caused no significant change in anisotropy but increased the L_c value significantly and, in addition, decreased the X-ray background intensity in the vicinity of the (002) reflexion. This suggests that the abnormally high modulus in low-temperature deposits is associated with their characteristically 'nongraphitic' structure. It is possible that cross-linking between the layer planes in-

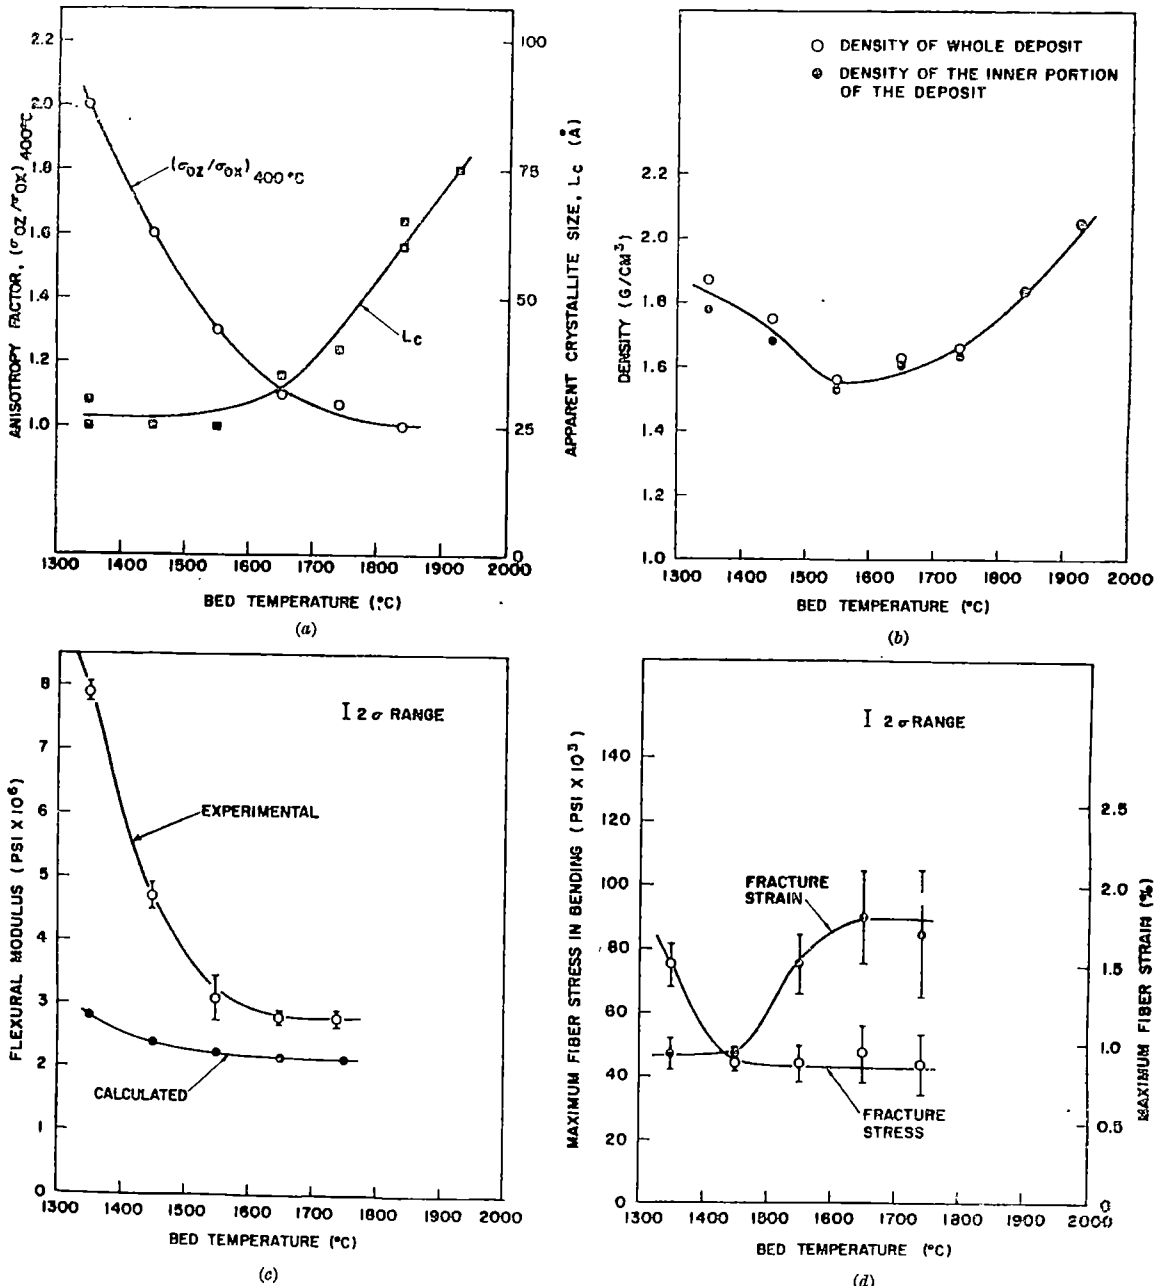

Fig. 1. Dependence of structural parameters and room-temperature mechanical properties on deposition temperature for pyrolytic carbon deposited in a fluidized bed: (*a*) anisotropy factor and apparent crystallite size, (*b*) density, (*c*) flexural modulus, and (*d*) maximum fibre stress and strain at fracture

creases the shear modulus within the crystallites to a value much higher than that of graphite.

The rapid decrease in the modulus, together with the slower decrease in fracture stress as the deposition temperature increases, results in a net rise in fracture strain as the bed temperature increases. Fracture strains of about 2 per cent were observed in material deposited above 1,600° C, which is about 10 times higher than that observed in conventional nuclear graphites. In addition, the fracture strain in the specimen deposited at 1,350° C and annealed at 2,300° C rose from 1·4 to 2·5 per cent on annealing, while the fracture stress fell from 77,000 lb./in.² to 56,000 lb./in.². These results show that more elastic strain can be accommodated before fracture in the high-temperature (or annealed) deposits than in the low-temperature deposits. This result has some practical importance in the design of structures (for example, nuclear-reactor fuel bodies) which utilize pyrolytic-carbon coatings.

Interpolation of Franck–Condon Factors

In recent years, much effort has been expended to provide arrays of Franck–Condon factors $q_{v'\,v''}$ for many molecular band systems, particularly those of astrophysical and aeronomical interest because of the rapid growth of quantitative spectroscopic activity in aerospace and related fields. Many different straightforward analytical and numerical methods have been used in the calculation of q-arrays of various sizes appropriate to a number of molecular potentials of which the Morse potential has been the most popular. The calculation of a $q_{v'\,v''}$ array is in principle a simple task, though often formidable if an electronic computer and appropriate programme are not available.

In spite of the activity, many band systems remain to be treated. Some potential users of $q_{v'\,v''}$ values whose need for the data are, for example, for definitive identification of bands or band systems, or for estimates of radiative heat transfer from hot gases, are often satisfied by order of magnitude estimates of $q_{v'\,v''}$. It would thus be valuable to have a simple means of making such estimates. To this end it is natural to consider whether some form of interpolation could be applied to the $q_{v'\,v''}$ arrays which have already been calculated. A transition parameter t which varies from band system to band system and which may be used for interpolation is therefore required in order that plots of $q_{v'\,v''}$ versus t can be made for each (v', v'') band of interest.

The steady and systematic change of Franck–Condon factor surfaces from a sharp diagonal ($v'=v''$) ridge to broad axially symmetric nested horseshoe-shaped ridges and valleys, as Δr_e (the change in equilibrium internuclear separation) steadily increases[1], implies that Δr_e will be incorporated in any transition parameter. $q_{v'\,v''}$ is the vibrational overlap integral square and is thus controlled by the extent of overlap Δr between the two potentials at v' and v'' respectively. If r_1 and r_2 are respectively the smaller and larger of the classical turning points of the molecular oscillator in the v'th vibrational level, Δr can take the four possible values $r_2''-r_1'$, $r_2'-r_1'$, $r_2''-r_1''$, $r_2'-r_1''$, depending upon the relative position and widths of the two potentials. A 'gross' Δr which might be applied to a whole band system (rather than just to the $v'-v''$ band) is proposed to be the overlap between the two potentials at, say, the D/K height of each, where D is the dissociation energy and $1/K$ is any fraction. A non-dimensional transition parameter $t=\Delta r_e/\Delta r$ is then proposed. It is relatively easy to show that for each of the above four values of Δr, and apart from an arbitrary constant involving the choice of K, that $\beta\ \Delta r_e$ is a very good approximation to t. β is the harmonic mean of the coefficients β' and β'' of $(r-r_e)$ in the two Morse potentials involved. (This is similar to the parameter $\bar{\beta}\ \Delta r_e$ which was suggested some years ago[2] on purely empirical grounds for interpolation of approximate q-arrays. $\bar{\beta}$ is the arithmetic mean of β' and β''.)

The usefulness for interpolation purposes of $\beta\ \Delta r_e$ as a transition parameter has been tested in plots of $\log q_{v'\,v''}$ versus $\log t$ for many (v', v'') combinations using $q_{v'\,v''}$ values taken from the 85 arrays of 'Morse' Franck–Condon factors ($0{\cdot}02 < t < 4{\cdot}7$) which have so far been computed to high quantum numbers using a straightforward method which has been described in detail elsewhere[3]. The plots are smooth and undulating with remarkably little scatter. If the plots are themselves arranged in a $v'-v''$ Deslandres array, it is observed that along the rows and columns $v_t=n$, $v_f=n$, $n+1\ldots$ (v_t or $v_f=v'$ or v'' respectively), each of the plots exhibits n maxima each of which moves to larger t as n increases. The maxima occur where a Condon locus[4] moves through (v', v'') as t increases. A provisional approximate q-array can be read from such plots for an uncomputed band system the transition parameter, t, of which has been evaluated.

GEOCHEMISTRY

Genetic Type of the Source Material for Common Leads

Recently the following formula was presumed[1,2] to hold in general between the concentration (C_x) of minor element X in a liquid and the corresponding concentration (C_x') in an infinitesimal solid just separated from the liquid:

$$\frac{C_x'}{C_x} = \text{constant} = k_x \qquad (1)$$

where k_x is defined as a partition coefficient of element X. Mathematical development of this general equation and application of its result to a triple combination of lead, thorium and uranium led to[3]:

$$\log(C_U/C_{Pb}) = b\log(C_{Th}/C_{Pb}) + \log(C_U^0/C_{Pb}^0) - b\log(C_{Th}^0/C_{Pb}^0) \qquad (2)$$

$$\log(C_U'/C_{Pb}') = b\log(C_{Th}'/C_{Pb}') + \log\{(C_U^0\,k_U)/(C_{Pb}^0\,k_{Pb})\} - b\log\{(C_{Th}^0\,k_{Th})/(C_{Pb}\,k_{Pb})\} \qquad (3)$$

and

$$b = (k_{Pb} - k_U)/(k_{Pb} - k_{Th}) \qquad (4)$$

where C^0 refers to concentration of subscripted element in the initial material for the Earth's oxide sphere. Equation (2) expresses the change of relative concentrations of the elements concerned in liquid, and equation (3) the corresponding change in solid, with the progress of crystallization of silicate melt. These equations indicate that the relative changes of logarithms of concentration in liquid and solid are expressed graphically by two straight lines running parallel with each other. In turn it is not only possible but also of much significance to decide whether a correlation observed for abundances of some elements represents liquid or solid.

The treatment of data on isotopic analyses of common leads in ores has brought about the relationship[1] written by:

$$\log(C_U/C_{204}) = 0{\cdot}503\log(C_{Th}/C_{204}) + 0{\cdot}231 \qquad (5)$$

where C_{204} stands for the concentration of lead 204, not of whole lead. It was pointed out[3] that in reducing the relevant chondritic abundances to equation (5) gave a result in agreement with the empirical equation (5), in fact suggesting that the source material for common leads is of a liquid type, not solid.

According to our model[1,2] based on the geochemistry of lanthanides, on the other hand the rock of the mantle as a whole is inferred to be a solid-type material which represents the aggregate of crystals segregated from the liquid. The partial melting of the mantle material can

produce a liquid-type material resembling the melt which would have been in equilibrium with the very mantle material of a solid type in the course of formation of mantle. Thus, so far as the directly observed concentrations of minor elements are concerned, we can explain the rise of liquid-type material in terms of the regeneration of liquid-type material from solid-type material by partial melting. However, it must be noted here that the abundance relation obtained from isotopic composition of lead cannot be affected by whether the material of source of lead encountered the partial melting or body melting, but indicates the relationship in the material of the source itself. In addition, it must be realized that the empirical equation (5) was obtained by assuming that the source material for common leads had been segregated and fixed at the time of formation of mantle ($4{\cdot}55 \times 10^9$ years ago). Therefore, the empirical formula implies that the liquid-type material has existed within the upper mantle almost since the formation of the mantle itself. This sequence of isotopes of lead may appear to be inconsistent with our model for mantle. However, an explanation compatible with our model is possible. That is to say, the problem can be solved by assuming that a minute fraction was isolated as liquid within the mantle and then frozen as pockets at or shortly after the time of formation of the upper proto-mantle, and that common leads originated from such a liquid-type relic material. Probably this material may be liquids occluded at the time of formation of upper mantle or those reproduced by partial after-melting shortly after the formation of bulk mantle. The latter possibility is preferable to the former with our model of the mantle, for it demands no modifications of the model.

Moreover, we cannot rule out the possibility that the present crust was generated secondarily as a residual liquid-type material through solidification of re-molten primary liquid-type material which could have thicknesses of, say, 100–400 km.

Moreover, as already stated here, it is essentially important to distinguish between solid type and liquid type for the genetic type of the natural material in hand.

Composition of the Metallic Phases in some Stone and Stony-Iron Meteorites

Ten chondrites and two siderolites have been investigated, using electron-probe microanalysis to measure the concentration of nickel in the metallic phases. Information about the composition of the metal particles in chondrites is of value in deciding whether they were formed *in situ* or by the accumulation of fragments of large metallic bodies. Conventional chemical analysis is limited to determining the average composition of the metal, owing to the smallness of the particles. Ringwood[1] measured the lattice parameters of the kamacite (α-nickel–iron) and tænite (γ-nickel–iron) in a number of chondrites, and deduced compositions from these measurements. It is preferable to use a more direct method of obtaining compositional information: electron-probe microanalysis has the advantage for this purpose of combining reasonable precision ($\pm$ 1 per cent of the concentration measured) with high spatial resolution (about 1μ).

The results of the electron probe measurements are given in Table 1. The chondrites are listed in order of increasing fraction of metal present. They range from Dhurmsala with 3 per cent of metal[2] to Forest City with 24 per cent[3] and the average nickel content of the metal ranges from 22 per cent in the former to 6 per cent in the latter[4]. The classification used here is as given by Prior and Hey[4]. In general, the relative abundances of kamacite and tænite were found to follow the expected pattern, with the specimens at the top of the list containing mostly tænite with only a little kamacite, and the proportions reversed at the bottom. In some specimens (L'Aigle, Tabor, Limerick and Forest City) the individual kamacite grains were essentially homogeneous, while varying in composition from grain to grain. In Chantonnay the kamacite was homogeneous and did not vary between grains. In other cases the kamacite was appreciably inhomogeneous. The Dhurmsala specimen contained only one grain of kamacite. In Table 1 the kamacite compositions are given in the form of the range of nickel concentrations found. The tænite was generally highly inhomogeneous, as in the iron meteorites: the figures given in Table 1 represent the maximum nickel concentration in tænite in each specimen. In Pultusk and Mauerkirchen a few grains of a different form of tænite were found: these were much less variable in composition than the more usual variety and contained about 50 per cent nickel and 50 per cent iron. In grains as much as 50μ across, the nickel concentration varied only slightly, whereas most of the tænite was highly inhomogeneous over distances of the order of microns. In the two siderolites the variation in kamacite composition took the form of a reduction in the nickel concentration in the immediate vicinity of kamacite/tænite interfaces, similar to that observed in iron meteorites[5]. The distribution of nickel in tænite was found to be essentially the same in these specimens as in iron meteorites: the nickel concentration rises to a maximum at the interface with kamacite. The nickel concentrations in tænite in the siderolites given in Table 1 represent the maximum values obtained.

Table 1

Name	Type	Wt. % Ni in kamacite	Max. wt. % Ni in tænite
Dhurmsala	Intermediate hypersthene chondrite	4·9	48
Knyahinya	Polymict brecciated grey hypersthene chondrite	5·6–7·0	47
Mauerkirchen	White hypersthene chondrite	6·2–6·6	50
Chantonnay	Polymict brecciated grey hypersthene chondrite	7·2	37
Mooresfort	Veined grey chondrite	6·6–7·4	45
L'Aigle	Brecciated intermediate hypersthene chondrite	6·6–7·2	52
Pultusk	Veined grey hypersthene chondrite	6·4–6·8	50
Tabor	Brecciated spherical bronzite chondrite	6·6–7·5	44
Limerick	Veined grey bronzite chondrite	6·4–7·4	50
Forest City	Brecciated spherical bronzite chondrite	6·7–7·3	47
Estherville	Mesosiderite	4·9–7·4	55
Krasnojarsk	Pallasite	6·1–7·4	50

The concentrations of nickel in kamacite in the ten chondrites investigated varied from 4·9 to 7·5 per cent, with the siderolites falling within the same range. This is very similar to the range of compositions found in iron meteorites[6]. The observed tænite compositions are also comparable. Anders[7] has shown that the metal particles in chondrites probably developed their structures *in situ*, as the result of spending a long time in the $\alpha + \gamma$ region of the phase diagram, at temperatures more than 450° C. The results reported here are consistent with this interpretation. The observed kamacite and tænite compositions correspond to temperatures of about 350°–450° C, according to the iron–nickel phase diagram of Owen and Liu[8]. These figures are approximate only, in view of the unknown effect of co-existing troilite and silicates. The inhomogeneity of tænite indicates that cooling from higher temperatures occurred, the observed compositions being those reached at the 'freezing-in' temperature, below which no further diffusion could take place in the time available.

I thank Dr. J. V. P. Long for his advice and help, Dr. S. O. Agrell for supplying the specimens and Dr. G. F. Claringbull of the British Museum (Natural History) for supporting this work.

CRYSTALLOGRAPHY

Crystal Structure of Lamprophyllite

A specimen of the mineral lamprophyllite (from Kola, the U.S.S.R.) at present being investigated is monoclinic, space group $C2/m$, with unit cell dimensions: $a = 19{\cdot}76$ Å, $b = 7{\cdot}06$ Å, $c = 5{\cdot}40$ Å, $\beta = 96{\cdot}5°$. The unit cell formula is: $4 \times (Ba,Sr,K)Na(Ti,Fe)TiSi_2(O,OH,F)_9$.

Using 174 $hk0$ reflexions, the structure has been determined in projection along the z-axis. The atom positions found are given in Table 1 and the projection along the z-axis is shown in Fig. 1. The short repeat distance of the z-axis enables the main features of the structure in three dimensions to be determined unambiguously.

The structure is closely related to those of the minerals seidozerite[1], rosenbuschite[2] and bafertisite[3]. The basic unit is an infinite sheet of cations, chiefly sodium and titanium, in octahedral co-ordination. To either side of this are attached sheets of silicon–oxygen tetrahedra and titanium–oxygen polyhedra arranged as shown in Fig. 2.

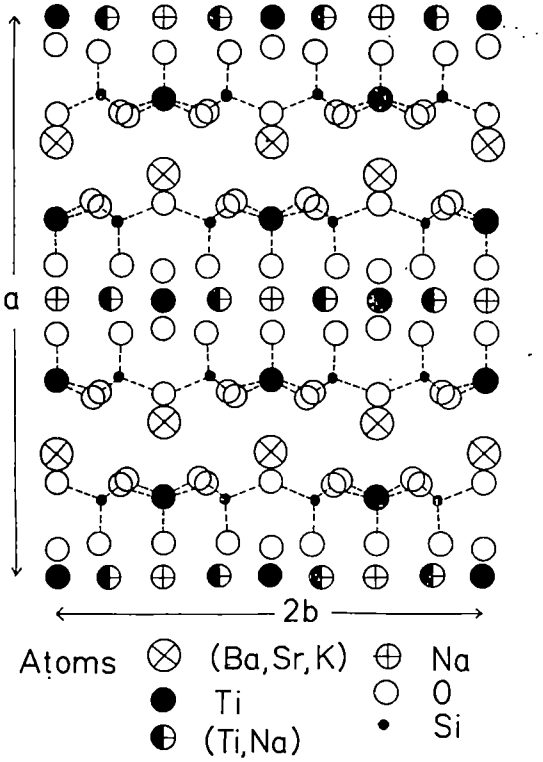

Fig. 1. Lamprophyllite projection along z-axis

Table 1. Atom Co-ordinates

Atom	x	y
(Ba, Sr, K)	0·217	0·000
Si	0·140	0·217
Ti	0·000	0·000
(Ti, Na)	0·000	0·239
Na	0·000	0·500
Ti	0·146	0·500
O	0·056	0·000
O	0·059	0·205
O	0·062	0·500
O	0·165	0·310
O	0·173	0·312
O	0·174	0·000

These composite sheets are separated by barium atoms. The titanium–oxygen polyhedra shown in Fig. 2 are square pyramids, the titanium being in five-fold co-ordination. In this respect lamprophyllite differs from the minerals mentioned above, in which the titanium, or zirconium in some cases, is in six-fold, octahedral, co-ordination.

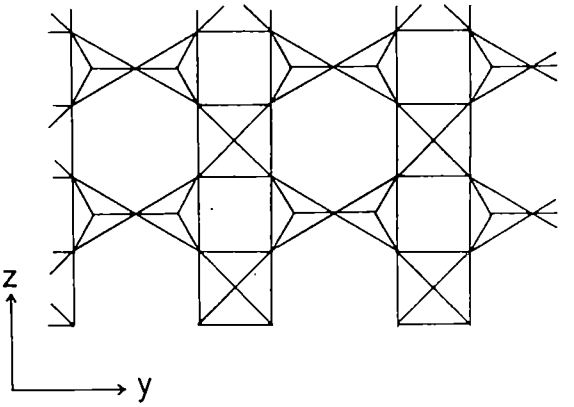

Fig. 2. Arrangement of SiO_4 and TiO_5 polyhedra

Work is in progress to determine directly a second projection of the structure.

CHEMISTRY

Aluminium Oxyfluoride and the Polymerized Species in AlOCl Solutions

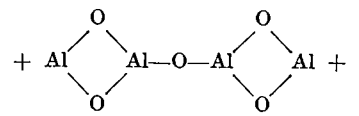
Although the crystalline aluminium oxyhalides AlOCl, AlOBr and AlOI are known[1–3], the corresponding AlOF is not. We have tried to prepare AlOF by the procedure which is commonly used to prepare the other AlOX compounds, namely, the reaction of 3 AlF_3 with As_2O_3 in sealed evacuated glass ampoules at elevated temperatures. However, AlOF was not formed at temperatures up to 480° C, although reaction between AlF_3 and As_2O_3 did occur. Details of these experiments will be published elsewhere. Whereas AlOCl can be prepared by the reaction of steam and $AlCl_3$ (ref. 4), it does not appear that AlOF can be prepared by a comparable reaction with AlF_3. Schober and Thilo[5] found that AlF_3 reacts with steam at temperatures up to 600° C to form a product with a 5·2 per cent fluorine content, and lower fluorine contents at higher temperatures. They formulated their product as $Al_7O_{10}F$. Locsei[6] obtained similar results but preferred to formulate the product as a mixture of Al_2O_3 and AlOF. No reason

was given for the latter choice, but even if it were correct the product would be predominantly Al_2O_3.

We have approached the preparation of aluminium oxyfluoride differently, by the reaction of an aqueous solution of AlOCl with silver fluoride. However, as will be shown, the simple metathetical reaction AlOCl + AgF → AlOF + AgCl does not occur. Instead, equimolar amounts of AlF_3 and an oxyfluoride $Al_4O_5F_2$ are formed. We believe the seemingly unusual course of this reaction provides the answer to a long-standing problem as to the nature of the species present in aqueous AlOCl solutions. That AlOCl in water solution is not simply hydrated AlOCl or AlO^+ and Cl^- has long been known. Kohlschütter *et al.*[7] showed by freezing point depression, specific conductivity and potentiometric titration data that the Al(III) species in aqueous solutions of $Al(OH)_2Cl$ (or AlOCl) must be present in the form of polymerized ions. They predicted the presence of cations containing 3 or 4 aluminium atoms but were unable to deduce the specific formula.

A recent observation[1] that anhydrous AlOCl reacts readily with water at room temperature to form water-insoluble AlO(OH) and HCl is puzzling. Previous work indicates that solutions of $Al(OH)_2Cl$ are quite stable[7], and it is certainly reasonable to presume that solutions of AlOCl in water would be the same as those of $Al(OH)_2Cl$. We have verified this point as follows. Using the same method of preparing anhydrous AlOCl as that of ref. 1, we found that 0·2 M solutions of AlOCl in water are only slightly hydrolysed over the temperature range 25°–100° C. These solutions exhibited a drop in *p*H, compared to that of distilled water, of somewhat less than one-half of a *p*H unit. This corresponds to hydrolysis of AlOCl of the order of 0·1 per cent; insoluble AlO(OH) was not observed. The equivalence of solutions prepared from anhydrous AlOCl with those of $Al(OH)_2Cl$ prepared by other means was also shown. Freezing-point depression and conductivity data for the AlOCl solutions were similar to the data reported by Kohlschütter *et al.* Furthermore, they isolated a hydrate, formulated as $AlOCl{\cdot}2{\cdot}7H_2O$ from aqueous $Al(OH)_2Cl$ solutions by vacuum distillation, while we obtained $AlOCl{\cdot}2{\cdot}5H_2O$ from our solutions.

Aqueous solutions of AlOCl were prepared by adding distilled water to anhydrous AlOCl[1], and filtering off a small non-soluble residue. The concentrations of the latter solutions and of aqueous AgF were each determined quantitatively by precipitation of silver chloride. The reaction between equivalent amounts of aqueous solutions of AlOCl and AgF instantaneously produced a precipitate, which was filtered. Elemental analysis showed that the supernatant contained an F/Al ratio of precisely 3·0, indicating that it was a solution of AlF_3; this was verified by vacuum distillation of the supernatant and X-ray diffraction inspection of the residue. The precipitate was dried to constant weight at 150°–170° C. In addition to a quantitative amount of AgCl, it also contained Al and F, in amounts consistent with the formulation $Al_{4\cdot00}O_{5\cdot04}F_{1\cdot96}$, with the oxygen obtained by weight difference and 7 mg out of a residue of 1·539 g attributed to residual water. The observed ratio of AlOCl consumed to AlF_3 formed was 4·94, while the corresponding ratio for $Al_4O_5F_2$ was 5·10. Within experimental error this is consistent with equation (1). The absence of AlF_3 from the precipitate



$$5\ AlOCl(aq) + 5\ AgF(aq) \rightarrow AlF_3(aq) + Al_4O_5F_2(s) + 5\ AgCl(s) \quad (1)$$

was evidenced by our inability to extract soluble fluoride from the precipitate despite several extractions with water, the fact that the supernatant contained only 0·00174 g AlF_3/g water, a value considerably below the reported solubility of AlF_3 (ref. 8), and the absence of AlF_3 from the X-ray diffraction spectrum of the precipitate. X-ray diffraction spectra of the latter were characteristic only of AgCl, the oxyfluoride producing no pattern.

$Al_4O_5F_2$ might be formulated as 2 AlOF + Al_2O_3, but this formulation would be inconsistent with the polymerized nature of AlOCl solutions. It would also require that three-fifths of the 5 AlOF initially formed somehow instantaneously disproportionates to AlF_3 + Al_2O_3 at room temperature. It is far more likely that $Al_4O_5F_2$ is a single compound, and that the formation of the latter and AlF_3 in equimolar amounts reflects the existence of the analogous chlorides in the original AlOCl solution. Thus the course of equation (1) suggests that AlOCl dissolves in water according to equation (2). Dissociation of $Al_4O_5Cl_2$ to $Al_4O_5^{+2}$ + 2 Cl^- not only produces a polymeric cation as predicted by Kohlschütter, but also provides the number of particles in solution required by the freezing-point depression and conductivity data. The data for 0·25 M solutions[7] require that each AlOCl unit in solution produce ~0·86 particles; $Al_4O_5^{+2}$ + 2 Cl^- + 1·13 particles per $AlCl_3$ (ref. 7) produces 0·83 particles per AlOCl unit. The agreement is also fairly good at 0·5 M, while the increase in freezing-point depression for 1-M solutions probably reflects an activity effect common for extensively hydrated salts in concentrated solution[9].

$$5\ AlOCl \xrightarrow{HOH} Al_4O_5Cl_2(aq) + AlCl_3(aq) \quad (2)$$

We postulate the following bridge-type structure for the $Al_4O_5^{+2}$ cation (not shown with water of hydration).

Autoxidation of Carbanions in Azoxybenzene

The unique ability of dipolar solvents to promote carbanion reactions has been the subject of two recent reviews[1,2]. More specifically, the use of a dimethylsulphoxide (80 per cent)–*tert*-butyl alcohol mixture as a medium for the autoxidation of carbanions[3,4] and *N*,*N*-dialkyl amides as media for the autoxidation of mercaptide ions[5–7] has been demonstrated. Zaugg[8] has shown that pyridine-*N*-oxide (PNO) is capable of accelerating the alkylation of enolate anions and other carbanions by alkyl halides in inert solvents. In the present communication, we report the results of our investigations in which we have attempted to use compounds containing an N–O linkage as solvents for base-catalysed oxidation reactions.

All oxidation experiments were carried out in a closed system under one atmosphere pressure of oxygen. Initially, pyridine-*N*-oxide (PNO) and azoxybenzene (AOB) were subjected to stability studies in the presence of base and oxygen. At 80°, a solution of 100 mmoles of potassium

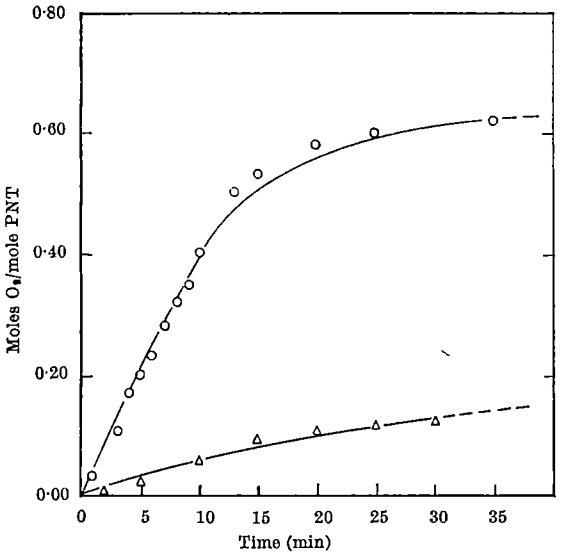

Fig. 1. Oxidation of *para*-nitrotoluene in azoxybenzene. ○, KOtBu −80°; △, KOH −110°

hydroxide in 75 ml. of PNO consumed 18·74 mmoles of oxygen in 68 h of reaction. Thus, it was concluded that PNO was not sufficiently stable to be used as a solvent for base-catalysed oxidations. On the other hand, AOB was found to be stable in the presence of oxygen and potassium hydroxide in the temperature region of 80°–110°. When a stronger base was used, AOB was also found to be highly stable. For example, a solution of 21 mmoles of potassium-*tert*-butoxide (KOtBu) in 150 ml. of AOB consumed only 0·84 mmole of oxygen in 25 h of reaction at 80°. These results prompted us to investigate some typical carbanion oxidations in AOB.

In our carbanion oxidation investigations, a two- to three-molar excess of base to hydrocarbon in 150 ml. of AOB was used. The rates of oxygen consumption were obtained by a wet-test meter and reactions were allowed to proceed until no apparent consumption of oxygen was observed[9]. Under these conditions, the oxidation of 12·5 mmole of *para*-nitrotoluene (PNT) at 80° in the presence of potassium-*tert*-butoxide (KOtBu) proceeded readily and gave essentially a quantitative yield of para-nitrobenzoic acid (1519, 1,710 cm^{-1}, m.p. 242°). Oxidation of PNT in the presence of potassium hydroxide was not possible at 80°. When the temperature was raised to 110°, a 38 per cent yield of *para*-nitrobenzoic acid was obtained. However, as shown in Fig. 1, the rate of oxygen consumption was considerably less than that observed with KOtBu at 80° (k(KOtBu-80°)/k(KOH-110°) = 7·2 based on initial rates). This reactivity sequence is consistent with an equilibrium reaction involving formation of the carbanion (equation 1) and subsequent rapid reaction of the anion with oxygen (equation 2).

$$p\text{-}NO_2\text{-}\varphi\text{-}CH_3 + RO^- \rightarrow p\text{-}NO_2\varphi\text{-}CH_2^- + ROH \quad (1)$$

$$p\text{-}NO_2\text{-}\varphi\ CH_2^- + 3/2\ O_2 \rightarrow p\text{-}NO_2\text{-}\varphi\text{-}COO^- + H_2O \quad (2)$$

The oxidation of other hydrocarbons in AOB has also been investigated. For example, the oxidation of 6·24 mmoles of diphenylmethane in KOtBu/AOB at 80° gave a 15 per cent yield of benzophenone in 21 h of reaction (KOtBu/DPM = 3). No attempt to determine the presence of a coupling product was made. In the presence of KOH, DPM could not be oxidized. Attempts to oxidize hydrocarbons less acidic than DPM in KOtBu/AOB were also unsuccessful. Thus, it would appear that the present system is capable of activating only relatively acidic hydrocarbons, for example the pK_a of PNT is about 20. Recently, we have demonstrated that toluene and ortho-xylene may be oxidized in a KOtBu-diphenylsulphoxide (DPSO) mixture at 100° (ref. 10). The dielectric constant of DPSO at 100° is about 16. At 100° the dielectric constant of AOB is about 4. Since DPSO and AOB have essentially the same stability in the presence of base and oxygen, the present results indicate that the dielectric constant of the solvent medium plays a key part in the initial ionization of the hydrocarbon.

Although no detailed mechanistic investigations were undertaken, it seems probable that the carbanion is initially autoxidized to an unstable peroxidic intermediate that later decomposes to a carbonyl derivative. Such a scheme has been proposed by Russell[11].

Production of $C_2O_4^+$ in an Ion-molecule Reaction

In an investigation of ion-molecule reactions in carbon dioxide in a magnetic sector mass spectrometer we observed the occurrence of a peak at *m/e* 88. By recording the ionization efficiency curve with the aid of an *XY* plotter, the curve shown in Fig. 1 was obtained. The break in the curve at about 38 eV is to be expected from the production of CO_2^+ by a charge exchange collision in the analyser portion of the instrument, that is, by the reaction:

$$CO_2^{++} + CO_2 \rightarrow CO_2^+ + CO_2^+$$

The portion of the curve above 38 eV follows the ionization cross-section curve obtained for CO_2^{++} (*m/e* 22) in the same instrument.

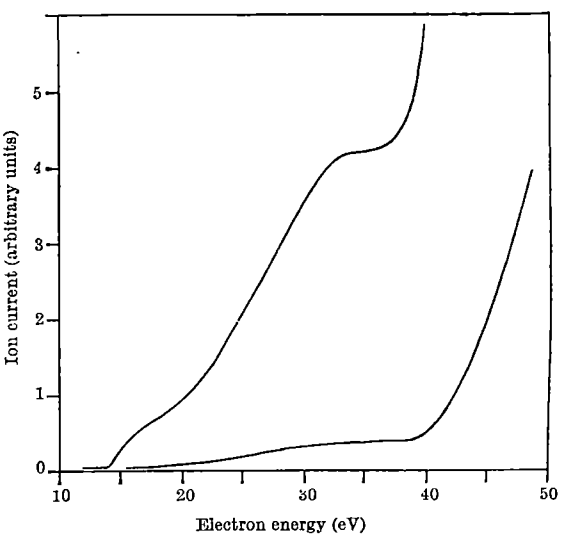

Fig. 1. Ionization efficiency curves for *m/e* 88. The upper curve was recorded with approximately 13 times the gain used for the lower curve

The portion of the curve in Fig. 1 from onset at 13·8 eV up to the break at about 38 eV was found to follow the ionization cross-section curve for CO_2^+ (*m/e* 44). With the use of an ionizing voltage of 35 eV, investigations of the effect of pressure of carbon dioxide in the ion source gave a curve for *m/e* 88 ion current versus pressure which was in excellent agreement with that expected for a three-body process. Variation of the repeller potential in the ion source indicated that, at an ionizing voltage of 35 eV, the ion current at *m/e* 88 behaved in a manner characteristic of an ion-molecule collision process, the current maximizing at a potential below that commonly observed for currents of primary ions. We conclude, then, that the ion current at *m/e* 88 observed in these experiments at ionizing voltages below the appearance potential of CO_2^{++} is due to the formation of $C_2O_4^+$ in the three body ion-molecule reaction:

$$CO_2^+ + 2CO_2 \rightarrow C_2O_4^+ + CO_2 \qquad (1)$$

We have estimated the gas pressure in the ion source by measuring the relative intensities of the CH_4^+ and CH_5^+ ions at several repeller field strengths, using published values[1] for the cross-sections of the reaction:

$$CH_4^+ + CH_4 \rightarrow CH_5^+ + CH_3 \qquad (2)$$

Pressure measurements obtained in this indirect way agree to within a factor of two with those estimated from consideration of the size of the leaks out of the source. In the work recorded here, the molecular number density in the source was about 7×10^{14} cm^{-3}. The rate constant for reaction (1) determined by the method described by Lampe, Franklin and Field[2] is found to be approximately 3×10^{-28} cm^6 sec^{-1} for primary ions of average energy 1 eV.

Polymeric species of carbon dioxide have previously been observed in experiments in which high-velocity streams of gas were sampled into a mass spectrometer[3,4], but these species were probably not the result of ion-molecule collisions. The ion $C_2O_4^+$ has been observed[5] in the negative glow region of a glow discharge in carbon dioxide at pressures of 0·1–0·6 torr. The present work suggests a probable source of this species. We have been unable to observe trimer ions of carbon dioxide in the pressure region up to 40μ.

Soap Micelles at the Oil/Water Interface

It has recently been shown that unimolecular films of long-chain fatty acids—stearic, behenic, cerotic, etc.—in fact possess a micellar structure[1–3].

The films are deposited on glass or mica slides by dipping them into solutions of the acids in a variety of hydrocarbon solvents. Under the electron microscope the acid molecules appear to be grouped together in micelles, or islands, their thickness being about 20–30 Å, their shapes and diameters varying with the chain-length of the acid and the nature of the hydrocarbon solvent. This is thought to occur because the cross-sectional area of the carboxylic head groups is greater than that of the hydrocarbon tail groups. The latter become tilted from the vertical, the amount of tilt increasing with distance from the centre of the micelle. At the periphery the tilt is so great that it becomes energetically more practicable for additional molecules to form into a new micelle rather than join an existing one[4].

An investigation has been made recently into the properties of adsorbed films of heavy metal soaps at the benzene/water interface, using the Wilhelmy plate method. In some instances the films were formed *in situ*[5] by dissolving the appropriate fatty acid in benzene and spreading this on to an M/2,000 solution of the metallic chloride. In other cases, preformed soaps in solution in xylene were spread at the interface with the aid of small amounts of iso-propanol. Very pure materials were used (Table 1) and the results obtained are shown in Table 2.

If it is assumed that at the low concentrations used the soap films are gaseous, the equation of state relevant to X g molecules of the soap at 30° is[6]:

$$Y \equiv \operatorname{Lm}_{\Pi \rightarrow 0} \Pi A = XRT = 2{,}519X \times 10^7 \text{ ergs}$$

Expressing Π in dyn cm^{-1} and A in square metres of the interface occupied by 1 mg of the soap,

$$\text{or} \qquad X = 10^{-3}/M \qquad M = 2{,}519/Y$$

where M is the apparent molecular weight of the soap and Y is the intercept on the ordinate of the graph of ΠA versus Π.

It is seen that the apparent molecular weights of the soaps are greater than the formula molecular weights, the aggregation numbers, n, ranging from about 20 for the decanoate down to about 9 for the stearates.

Now it is well known that in organic solvents the soaps of the heavy metals remain in the micellar form down to extremely low concentrations[7,8]. The results recorded here indicate that they are also in the micellar form when spread as a monolayer at the oil/water interface. At this interface the soaps will be slightly ionized: hydroxyl groups will be expected to increase the effective cross-sectional area of the heads and thus favour tilting of the tails.

The number of molecules per micelle, and hence their size, decreases with increasing hydrocarbon chain-length. This is in agreement with the prediction[4] for acid micelles in insoluble monolayers.

It will be interesting to see whether a suitable electron-microscopic technique can be developed for confirming that, at the oil/water interface, these and other films also exist in the micellar form, their cross-sectional areas being between 200 and 400 Å based on the number of molecules per micelle.

BIOPHYSICS

Diffusion Constants of Proteins determined by a Multi-unit Analytical Method

WHEN optical methods are not available, reliable diffusion constants may be obtained by techniques depending on the quantitative determination of the solute concentration in the diffusate such as the porous disk method of Northrop and Anson[1] (see also ref. 2). For these techniques a substance of known diffusion constant, established independently, is needed for calibration, which is a disadvantage.

An apparatus which requires no calibration and is easy to operate was described by Polson[3,4]. This is referred to as the multi-unit method and enables one to make observations at different time-intervals on the same substance, or different substances may be examined under identical conditions.

The apparatus consists of six independent units, each consisting of four stainless magnetic steel disks; a bottom fixed disk, a 2-cm, 1-cm and 0·5-cm section, the last acting as a lid. Each disk has six cylindrical holes arranged in a circular fashion which may be exactly aligned by proper rotation.

The sample to be examined is introduced into three alternate holes of the bottom disk, filling these completely, the holes in all four sections being in alignment. After filling these, the top three sections are rotated as a unit so that their cavities are shut off from the sample-containing disk. The dispersion medium is introduced into three alternate holes of the top unit filling the two central sections completely. After proper rotation of the lid to seal the units, the apparatus is submerged in a thermostatically controlled water bath to reach temperature equilibrium. The samples and dispersion medium may then be opposed by rotating the top three sections, including the lid, as a unit. The experiment is terminated by similar rotation of the sections at exactly timed intervals. The contents of the top section are withdrawn after adequate mixing and the concentration of the diffused substance determined by suitable means. In the case of proteins, absorption at 280 mμ and a modification of Weichselbaum's biuret procedure[5] have been found satisfactory.

The diffusion constant is calculated from the equation:

$$D = \left(\frac{C_t}{C_0} H\right)^2 \frac{\pi}{t}$$

(for its derivation see Polson[3]).

In this equation C_t/C_0 is the ratio between the concentration of the substance in the diffusate and in the original solution. H is the height of the column containing the diffusate and t is the duration of the experiment in seconds.

By plotting C_t against $\sqrt{t}$ a straight line passing through the origin is obtained. Fig. 1 represents the results obtained in an experiment on γ-globulin prepared by the polyethylene glycol procedure[6].

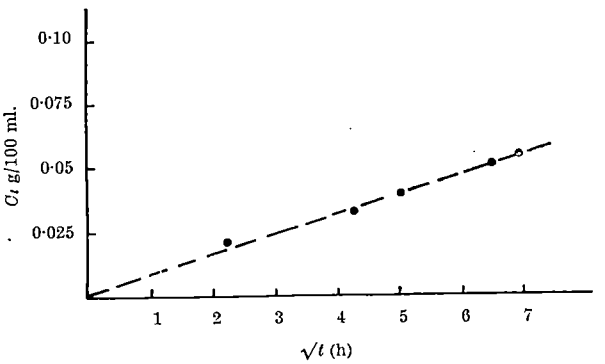

Fig. 1. Diffusion experiment on human γ-globulin. The concentration of protein in the diffusate is plotted against the square root of the time of diffusion $C_0 = 0{\cdot}963$ g/100 ml. Saline $T = 23{\cdot}5°$ C

In Table 1 the diffusion constants of several proteins as determined by the multi-unit technique and the well-known Lamm-scale method are compared. There is good agreement between the two sets of values although the latter method gave slightly higher figures because these were derived by extrapolation to infinite dilution.

Table 1. DIFFUSION CONSTANTS OF SOME PROTEINS AS DETERMINED BY THE MULTI-UNIT APPARATUS AND LAMM-SCALE METHOD

Protein	Concentrations in g/100 ml.	Multi-unit apparatus $D \times 10^7$ cm²/sec	Lamm-scale method $D \times 10^7$ cm²/sec	Ref.
Ovalbumin	0·8	7·60	7·63	8
Human hæmoglobin	1·0	6·60	6·90	8
γ-globulin	0·963	4·80	4·81	7
Jasus lalandii hæmocyanin	1·4	3·39	3·40	9

The discrepancy between the results obtained on γ-globulin and the figure of $4{\cdot}2 \times 10^{-7}$ cm²/sec usually adopted for this protein may be explained by the absence of macroglobulins in our preparations, as shown by ultracentrifugation[6,7].

This method has been used successfully in determinations of diffusion constants on unpurified samples of biologically active material such as the soluble antigens of viruses[10–12].

This investigation was supported in part by a U.S. Public Health Service research grant *AI* 04044–03 from the National Institutes of Health, Bethesda.

BIOCHEMISTRY

Inhibition by Ouabain of Glycolysis in Ciliary Body

Much recent work has indicated that in tissues with a high secretory or nervous activity the rate of aerobic metabolism may be determined by the activity of the ion transport mechanism. This control is effected through the levels of ADP and ATP in the cell, which vary according to the activity of the sodium–potassium stimulated ATPase, the enzyme which governs sodium transport[1]. It has been shown that ouabain, a specific inhibitor of sodium–potassium ATPase, causes a 40 per cent decrease in the rate of oxygen uptake in kidney[2] and in liver[3] and a 30 per cent decrease in brain[4].

Schatzmann[5], using erythrocytes, had found no effect of ouabain on the glycolytic rate, but during the course of the present work Whittam[6] reported that lactate production by these cells is inhibited to the extent of 16 per cent by ouabain.

Ciliary body, which has a high rate of sodium transport[7] and a high sodium–potassium ATPase activity[8,9], exhibits a high rate of aerobic glycolysis in addition to its respiratory activity[10]. It has been found[11] that the oxygen uptake of the tissue is inhibited in the presence of ouabain by 64 per cent.

To investigate the effect of control of the transport mechanism on glycolysis, strips of pig ciliary body were incubated in Warburg flasks with the addition of ouabain to the medium or the replacement of sodium ions by *tris* or choline. Glucose and lactate were measured at the beginning and end of the experiment by the methods of Marks[12] and of Barker and Summerson[13], respectively.

The absence of sodium ions or the presence of ouabain had identical effects. Lactate production was inhibited 61 per cent when the atmosphere was 100 per cent oxygen and 45 per cent when the atmosphere was nitrogen. Glucose utilization was similarly reduced by 53 and 41 per cent. Under anaerobic conditions there was no appreciable change in the lactate : glucose ratio, 90–95 per cent of the glucose being converted directly to lactate. Under aerobic conditions, however, there was a fall in the ratio from 1·6 to 1·3 and preliminary experiments indicate that there is a relative increase in the amount of glucose metabolized via the pentose phosphate pathway although total oxygen uptake is decreased by 64 per cent.

It is of interest that the inhibition of glycolysis of the ciliary body should be so much greater than that found in erythrocytes, as these cells obtain their total energy requirement for transport from the glycolytic system. Further, the respiratory inhibition is greater than that found in brain, kidney or retina[11]. In the case of the respiratory inhibition it could be argued that in the ciliary body a greater fraction of the available energy supply is directed solely towards sodium transport, whereas in brain, kidney or retina other processes such as synthetic mechanisms are able to maintain a supply of ADP. The sodium–potassium ATPase activity of each of these tissues constitutes a relatively high fraction of 'total' ATPase[8], but under those conditions of assay the indirect sources of ADP were not measured. Thus, in the whole cell, inhibition of respiration would reflect the true fraction of the overall ADP supply which is determined by the sodium-transporting mechanism.

On the basis of the foregoing argument, inhibition of glycolysis in red cells would be expected to be higher than the 16 per cent reported by Whittam[6], as sodium–potassium ATPase comprises about 50 per cent of the total ATPase. However, although there will not be a large yield of ADP from synthetic processes, it is possible that hexokinase and glucose-6-phosphatase might provide an adequate turnover of ADP to relieve inhibition. Alternatively the high inhibition of glycolysis in ciliary body, especially under aerobic conditions, may be dependent on more complex relations with mitochondrial requirements for ADP.

Table 1. Inhibition of Glycolysis of Ciliary Body by Ouabain

	Glucose utilized (μmol./100 mg wet wt.)		Lactate produced (μmol./100 mg wet wt.)	
	Control	+ Ouabain	Control	+ Ouabain
Aerobic 100 per cent O_2 (8)	3·1 ± 0·5	1·5 ± 0·5	4·7 ± 0·9	1·8 ± 0·5
Anaerobic (5)	3·7 ± 0·3	2·2 ± 0·5	6·9 ± 0·6	3·9 ± 0·9

Flasks contained PO_4^{3-} 18 mM, Cl^- 117 mM, Mg^{2+} 1·2 mM, K^+ 30 mM, glucose 3·3 mM. Na^+ or *tris* was 117 mM. Ouabain 0·3 mM. Incubation was for 50 min at 37° C.

The inhibition of glycolysis is presumably effected at one or both of the two sites of phosphorylation, as Whittam has suggested[6], a decrease in the rate of hydrolysis of ATP resulting in a lack of ADP for the phosphokinase reactions. In ciliary body and retina (the only animal tissues, apart from tumour cells, that have a high aerobic glycolysis) transport controls, in part, the energy production from both processes. It thus appears that both glycolytic and mitochondrial ATP may be used as the substrate of the membrane ATPase.

This is supported by the fact that, although aqueous humour formation is oxygen-dependent, under anoxic conditions a fraction of the sodium transport is maintained[14].

Amino-acid Composition of Prekeratin

In a previous communication[1] a new isolation technique was described by which pure prekeratin can be obtained from the epidermis of the cow's nose. For the extraction of the epidermis 0·1 M citric acid–sodium citrate buffer of *p*H 2·6 and ionic strength of 0·6 was used and prokeratin was isolated from the epidermal extract by serial precipitations in the *p*H range of 4·5–7·0. The prekeratin obtained by this method has a molecular weight of 640,000 and consists of highly asymmetric particles which reveal a typical α-keratin pattern in X-ray diffraction investigation. The chemical composition of this prekeratin was recently determined and the results are reported here.

Prekeratin contains 2·9 per cent lipid that is extractable in hot ethanol, and less than 0·1 per cent carbohydrate as measured by the orcinol test. Its amino-acid composition, as determined by automated columnar chromatography with the Technicon auto-analyser, is shown in Table 1. The amino-acid composition of three different preparations of prekeratin was examined after hydrolysis in 6 N hydrochloric acid at 110° C for 24, 48 and 72 h. Corrections for the destruction of threonine, serine and tyrosine were made by extrapolation to zero time of hydrolysis. The sulphur-containing amino-acids were determined by using performic acid oxidation prior to hydrolysis[2]. The tryptophan content was estimated by the spectroscopic method[3]. The total nitrogen content of the samples was 16·16 per cent as determined by the Kjeldahl method.

Table 1. Amino-acid Composition of Prekeratin

Total N 16·16%	Amino-acid g/100 g protein	Amino-acid residue g/100 g protein	Nitrogen as % of total nitrogen	No. of residues per protein molecule (m.w.: 640,000) Calculated	Nearest integer

Amide NH_3	1·79	—	9·10	—	—
Total	114·05	97·12	102·08	—	5,534

The amino-acid composition of this prekeratin differs from previously examined keratin[4] and prekeratin preparations[5]. Its most salient feature seems to be a low content of proline and sulphur-containing amino-acids. The low proline content would be expected because most α-proteins contain very small amounts of this amino-acid. The low content of sulphur-containing amino-acids, on the other hand, is unexpected and indicates that epidermal prekeratin may be stabilized only by a small number of disulphide cross-linkages. The calculations indicate that there are only about 76 half-cystine molecules in one prekeratin molecule (Table 1); this would account for only 38 disulphide linkages, which is a very small number for a large molecule with a molecular weight of 640,000.

Electrophoretic Behaviour of Serum Angiotensinase

When angiotensin is introduced into the circulation, it quickly disappears as a result of degradation by serum angiotensinase, and uptake by the tissues and degradation by their respective angiotensinase activities. To elucidate whether serum angiotensinase activity results from one single enzyme or from non-specific amino-peptidases, its electrophoretic behaviour was compared with that of five other amino-peptidases.

In a first group of experiments, serum was separated by micro-electrophoresis in agar gel according to Scheidegger[1]. 0·03 ml. of the serum was allowed to migrate at room temperature for 100 min in veronal buffer at *p*H 8·6, under a potential of 8 V/cm. The gel was cut into 15 strips, 0·5 cm wide, and each strip was eluted for 12 h at +4° C with 0·6 ml. of 0·9 per cent saline. The eluates, in 0·1-ml. fractions, were then incubated for 24 h at 37° C in 0·1 M phosphate buffer at *p*H 7·0 with amino-peptidase substrates at a concentration of $0{\cdot}35 \times 10^{-3}$; these substrates were: l-alanyl-β-naphthylamide-HCl (ABNA), l-cystine-di-β-naphthylamide (CYSBNA), l-glutamyl-β-naphthylamide-HCl (GLUNA), glycyl-β-naphthylamide-HCl (GLYNA), and l-leucyl-β-naphthylamide-HCl (LBNA). Liberated naphthylamide was determined by colorimetry according to Bratton and Marshall[2]. For measuring angiotensinase, valine-5-angiotensin II, aspartic-β-amide was incubated for 24 h with the eluates, at a concentration of $3{\cdot}9 \times 10^{-4}$; liberated amino-acids were separated by paper chromatography, and valine determined by densitometry according to Klaus *et al.*[3].

Table 1

	No. of cases	Substrate	Hydrolysis in % of the total activity of eluates α_1-	α_2-	β-	γ-globulin	Total activity of eluates	Activity in serum of origin (JE/ml.)
(1) Normal subjects	4	LBNA	88	12	—	—	25·0	29·4
		ABNA	88	12	—	—	35·2	42·6
		GLYBNA	87	13	—	—	11·8	15·1
		GLUBNA	90	10	—	—	8·7	11·4
		CYSBNA	—	—	—	—	—	0·6
		AT II	100	—	—	—	1·0	1·3
(2) Hepato-billary diseases	6	LBNA	69	21	2	8	122·0	134·1
		ABNA	71	19	2	8	158·0	171·1
		GLYBNA	74	20	2	4	50·3	58·1
		GLUBNA	74	19	2	5	51·8	60·7
		CYSBNA	81	19	—	—	3·4	4·1
		AT II	86	14	—	—	4·8	5·9
(3) Pregnancy ninth month	5	LBNA	84	12	1	3	190·0	211·6
		ABNA	84	11	1	5	157·0	168·1
		GLYBNA	87	10	1	2	60·0	69·4
		GLUBNA	89	5	1	5	53·2	63·8
		CYSBNA	86	14	—	—	6·1	6·8
		AT II	100	—	—	—	1·3	1·7

As shown in Table 1, total recovery from the eluates amounted to 70–80 per cent of original activity. Agar-gel microelectrophoresis gives a good separation of α_2-, β- and γ-globulin, but α_1-globulins migrate with albumin. In the sera of four normal subjects (Table 1 and Fig. 1), hydrolysis of ABNA, LBNA, GLUNA and GLYNA appeared as one broad peak in the α_1-region and extended slightly into the α_2-globulins. Angiotensinase was found only under the α_1-peak. CYSBNA hydrolysis was too low, in the sample, to be detected after electrophoresis. In the sera of six patients with hepatitis (Table 1, Fig. 2), aminopeptidase activity for all six substrates was increased. The highest peak of each of these activities migrated with the α_1-globulins; angiotensinase and CYSBNA-hydrolysis extended into the α_2-region; splitting of ABNA, GLUBNA, LBNA and GLYBNA was well extended into the α_2- and γ-globulin regions, and even detectable under the β-globulins. In the sera of five women in late pregnancy (Table 1) all aminopeptidases were increased except angiotensinase. Their electrophoretic distribution was similar to that of the hepatitis sera.

In a second series of experiments, plasma was separated by starch-block electrophoresis according to Kunkel and Wallenius[4]. Five ml. of plasma were dialysed and applied in a slit 20 cm long, and migration was carried out in 0·1 M veronal buffer at *p*H 8·6 at +4° C for 16 h under a potential of 5 V/cm. The block was cut into 25 strips of 1 cm × 20 cm, and eluted with 5 ml. of phosphate buffer 0·1 M at *p*H 7·4 over a fritted glass funnel. One

ml. of each eluate was incubated for 1 h at 37° C with angiotensin at a concentration of 1 μg/ml.; 2 min boiling stopped the reaction and residual pressor activity of the mixture was assayed in a rat preparation[5]. The results are shown in Fig. 3; in the plasma of four normal subjects, angiotensinase activity was detectable as a single peak in the α_1-region.

There is very little evidence, from the results obtained so far, for the existence of one specific angiotensinase. Although the maximum of the peak was consistently found with the α_1-globulins, activity became detectable in the α_2-region when there was a substantial increase in whole serum activity; this leads us to believe that much more sensitive methods could possibly have detected angiotensinase in other electrophoretic regions. The same reasoning may be applied to the hydrolysis of CYSBNA, the substrate used to determine cystine aminopeptidase or oxytocinase; it was also reported to migrate with the α_1- and α_2-globulins by Riad and Scandrett[6]. The main argument against one specific angiotensinase is that when it increased considerably during hepatitis, there was a comparable increase in all the other aminopeptidases in the same α_1-globulin peak. This main peak, formerly called leucine amino-peptidase, has been resolved by chromatography into several non-specific components by Behal *et al.*[7]. However, there is one of our observations which suggests that angiotensinase may differ somewhat from those other peptidases: the fact that during pregnancy they are all elevated except angiotensinase itself, which is thereby clearly distinguished from oxytocinase. It is interesting that, during pregnancy also, the splitting of LBNA and ABNA was preferentially increased over that of GLUBNA and GLYBNA; normal angiotensinase levels in pregnancy were reported before by Klaus *et al.*[3,8] and Landesman *et al.*[5].

The work of Nachlas *et al.*[9] and the results recorded here would seem to favour the existence, in the serum, of several non-specific amino-peptidases, overlapping in their amino-acid specificity and their electrophoretic mobility.

In normal serum, 2 LAP fractions have been reported to migrate in starch gel with the fast α_2-globulins[10,11] and in pregnancy and hepatobiliary disorders 3–7 additional bands have been described[10–14] in the slow α_2-, β- and γ-globulins. These data are very close to our findings with the substrates LBNA, ABNA, GLYBNA and GLUBNA, normal serum having activity mainly in the α_1-fraction and slightly in the α_2-, and hepatitis and pregnancy sera presenting additional peaks under the β- and γ-globulin areas. Identical results were reported on cellulose acetate by Rutenburg *et al.*[15]. It is conceivable that the β- and γ-globulin portions of these amino-peptidases exist in trace amounts in normal serum but escape detection by our methods; thus Behal *et al.*[16] could detect 4 LAP fractions in normal serum, using DEAE cellulose which can separate greater amounts of serum; in hepatobiliary disease, the increase of these four fractions was not accompanied by the appearance of new bands.

This work was supported in part by grant *HE*–07473 from the U.S. National Institutes of Health, U.S. Public Health Service. We also thank Prof. R. M. Archibald for providing laboratory facilities.

A New Variant of Transferrin from Greece

The transferrins are a group of iron-binding glycoproteins under genetic control which migrate in the β-globulin region on starch-gel electrophoresis[1]. Commonly there is a single iron-binding band called transferrin *C*, but faster (*B* variants) and slower (*D* variants) migrating iron-binding bands are occasionally present. Sixteen human transferrin variants have been described, which are controlled by the expression of codominant alleles at a single autosomal locus[2–6].

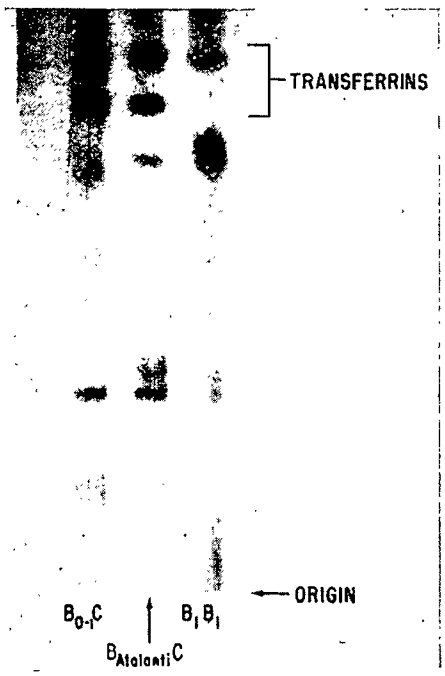

Fig. 1. Starch gel stained with amido black demonstrating that migration of $B_{Atalanti}$ is intermediate between B_{0-1} and B_1

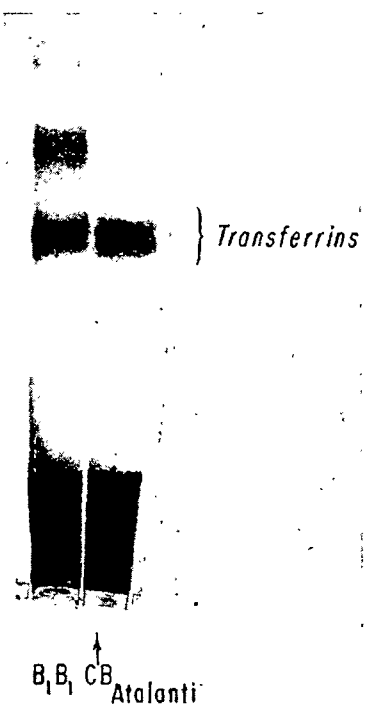

Fig. 2. Five per cent polyacrylamide gel stained with amido black demonstrating further that migration of $B_{Atalanti}$ is faster than B_1

This communication describes a new fast-moving *B* variant discovered during a survey of 709 specimens from ten Greek communities[7,8]. The variant was identified in the serum of a healthy 12-year-old school-boy from the city of Atalanti in Thessaly in Continental Greece and has been designated $B_{Atalanti}$. Its migration is slower than B_{0-1} and slightly faster than B_1 (Fig. 1). This mobility difference was repeatedly demonstrated on two separate serum specimens obtained from the propositus two years apart. The separation of the *B* variants seemed most distinct on vertical starch-gel electrophoresis at 4° C in borate buffer at *p*H 8·0 for 17–19 h at 9 V/cm. Under these conditions the *C* transferrin band migrated 5–5·5 in. from the origin. The mobility difference was also demonstrated on vertical electrophoresis at *p*H 9·0 in 5 per cent polyacrylamide gel (Fig. 2).

The propositus's father is phenotype transferrin *C*. Serum from his mother and sibs could not be obtained.

We wish to thank Dr. E. Giblett for providing the specimens of transferrin B_1B_1 used for comparison.

Origin of Urinary Resorcinol Sulphate

SOME human subjects have been shown to excrete large amounts of urinary resorcinol monosulphate ester[1]. This appears on paper chromatograms as a magenta spot after spraying with 2 per cent *p*-dimethylaminobenzaldehyde in 5 per cent v/v concentrated hydrochloric acid and heating at 55° C for 12–15 min. (The sensitivity of resorcinol sulphate to this reagent at room temperature is much lower and the resultant colour is grey.) The spot runs rather more slowly than indoxyl sulphate in isopropanol–0·880 ammonia–water ; 20 : 1 : 2 (R_F 0·50, 0·60 respectively), and also in *n*-butanol–acetic acid–water ; 12 : 3 : 5 (R_F 0·42, 0·46).

Meta-dihydroxy benzenoid compounds are unknown in human endogenous metabolism but common in the plant kingdom. Tea is the main dietary source in Great Britain of *m*-dihydroxy compounds, which could give rise to resorcinol *in vivo*. When tea was withheld from the two heavy excretors of resorcinol sulphate found in the original investigation, urinary excretion of this substance decreased to a trace or was undetectable after three days, reappearing as an intense spot on chromatograms after re-introduction of tea to the diet. Another subject who did not normally excrete resorcinol sulphate did not excrete it after drinking 15 cups of strong tea over a period of eight hours or after 10 cups of tea/day for five days. (The urinary chromogen derived from tea described by Fearon and Boggust[2] was excreted in large amount.) Thus urinary resorcinol sulphate appears to be a product of the metabolism of a tea constituent or constituents by certain subjects.

When one of the subjects (a schizophrenic in-patient) was re-investigated after an interval of six years he was found to be still excreting large amounts of resorcinol sulphate. On administration of 500 mg three times a day by mouth of the intestinal antibiotic framycetin (soframycin) together with his usual intake of tea, urinary resorcinol sulphate declined and was no longer detectable after six days. Thus resorcinol, like certain other aromatic constituents of urine including catechol[3] and *m*-hydroxy aromatic acids[4], is formed *in vivo* by intestinal bacteria, both the *m*-hydroxy acids and resorcinol being derived from dietary vegetable matter. Urinary indoxyl sulphate excretion, which gives some measure of the bacterial contribution to the urinary excretion of aromatic meta-

bolites in general[5], declined from 17·7 mg potassium indoxyl sulphate/g creatinine before antibiotic treatment to < 1·0 mg/g after six days treatment with framycetin. (The method of Curzon and Walsh[6] was used.)

Eight weeks after the termination of antibiotic treatment it was found that though 14·5 mg potassium indoxyl sulphate/g creatinine were excreted, resorcinol sulphate was not detectable. Similar observations were made on a urine sample collected 21 months later. Thus, it is suggested that urinary resorcinol sulphate originates from the action on dietary tea polyphenols of particular intestinal bacteria. Though when once established these may persist indefinitely, antibiotic treatment may result in their permanent disappearance. Chromatograms of urines of the father and brother of the subject who was investigated in detail also showed a significant resorcinol sulphate spot. This indicates that there may have been an initial infection of the family group when it was intact.

These findings illustrate that if it is suspected that a constituent of the urine of a particular patient is of dietary origin, the finding that other subjects on similar diets do not excrete it is not necessarily evidence in favour of an endogenous origin as qualitative intestinal bacterial differences may be involved.

We thank the staff of Friern Hospital for their co-operation and also the Joint Research Advisory Committee of the Institute of Neurology who financed some of this work.

PHYSIOLOGY

Effect of Amphetamine on Spinal Reflexes

L-Dopa (L-3,4-dihydroxyphenylalanine), precursor of catecholamines (adrenaline, noradrenaline and dopamine)[1], and DL-5-hydroxytryptophan (5-HTP)[2], precursor of 5-hydroxytryptamine, have recently been found to influence spinal reflexes. These drugs applied intravenously cause a pronounced increase of the flexor reflex evoked by pinching the skin. An electrophysiological investigation revealed that these drugs depress the short latency transmission of single volleys from the flexor reflex afferents (FRA, that is, Group II and III muscle afferents, cutaneous and high threshold joint afferents) to motoneurones, primary afferents and ascending pathways[3]. The depression of this short-latency FRA pathway accounts for the disinhibition of the long-latency pathway from the FRA to flexor motoneurones and I*a* primary afferents[4,5]. It has been suggested that the effect of L-DOPA and at least in part of 5-HTP is accounted for by increased synthesis and release of monoamines at the monoaminergic synaptic terminals in the spinal cord.

It was a matter of interest to ascertain whether drugs with analogous central effects act on spinal reflexes in a similar way. Amphetamine (*d,l*,β-phenyl-isopropylamine), well known for its central stimulant effects injected intravenously (3–6 mg/kg), has been found to give a pronounced increase of the flexor reflex evoked by pinching the skin in acute spinal cats. The effect appears within 2–3 min, reaches its maximum in 10 min and lasts for about 3–4 h.

'Amphetaminum sulphuricum' (Psychoton-Spofa) has been used in these and subsequent experiments which were carried out in an attempt to analyse further the mechanism of its action.

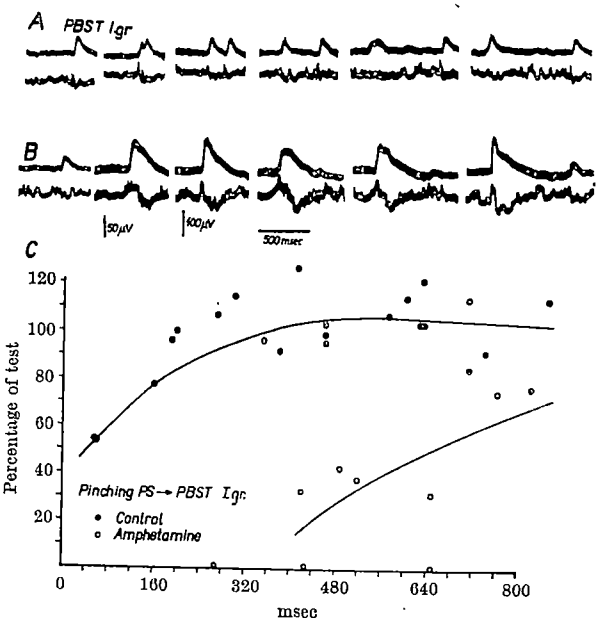

Fig. 1. *A* shows the DRPs evoked by a train of impulses of Group I from the posterior biceps-semitendinosus (PBST) conditioned by pinching the skin in the region of the superficial peroneal nerve (SP) at different intervals, the first record being the test response. *B* shows the effect of 3 mg/kg 'Amphetaminum sulphuricum', intravenous. The time course of the depression is shown in *C*. Calibration 50 μV relates to the upper and 100 μV to the lower beam

In acute spinal cats amphetamine inhibits short-latency transmission from the FRA to primary afferents to ascending pathways and to motoneurones. When this depression is very profound, long-latency discharges in flexor motoneurones with corresponding long-latency PRPs (dorsal root potentials) usually occur to short trains of stimuli. This action can be compared with that of L-DOPA and 5-HTP.

In an attempt to analyse the mechanism by which amphetamine increases the flexor reflex at the time when the short-latency FRA reflex action is depressed the action of amphetamine on spinal reflexes evoked by pinching the skin was examined. Amphetamine was constantly found to prolong the duration of reflex discharges in flexor motoneurones and to increase and prolong the duration of the DRP evoked by pinching the skin. Fig. 1 demonstrates the interaction between DRP evoked by pinching the skin and DRP evoked by a short train of stimuli from Group I primary afferents of the flexor nerve to the biceps posterior and semitendinosus (PBST) at different time-intervals (*A*) before and (*B*) after administration of 3 mg of amphetamine. In (*C*) the depression of the amplitude of Group I DRP evoked by a short train of stimuli to the PBST nerve is expressed in percentage and has been plotted against the time interval between the arrival of impulses evoked by pinching the skin in the region of the superficial peroneal nerve as recorded from the surface of the spinal cord. (All nerves except the cutaneous superficial peroneal nerve were sectioned.) In acute spinal cats sustained pinching depresses the Group I DRP for 200–300 msec (Fig. 1, solid circles). After amphetamine (open circles) the Group I DRP is totally suppressed for more than 400 msec and partially depressed for several seconds afterwards.

In acute spinal cats the depression of DRP from I*a* primary afferents followed by an FRA volley is not caused by their depolarization of the terminals in the spinal cord[6], but by the inhibition of the interneuronal chain between I*a* primary afferents[7]. That the mechanisms of the depression of Group I DRP induced by pinching the skin could be different was already suggested by experiments in which long-latency primary afferent depolariza-

tion after administration of L-DOPA was exclusively exerted on Ia primary afferent teminals[4,5].

Intraspinal excitability measurements from Ia fibres revealed their increased excitability for several seconds during pinching the skin when amphetamine had been given in a dose of 3–6 mg/kg. It can be concluded that amphetamine opens the pathway from FRA to Ia primary afferents by a mechanism which is probably analogous to the action of both L-DOPA and 5-HTP.

The sensitivity to amphetamine is not the same in all cats. In some experiments a dose of 3 mg/kg of amphetamine was sufficient to cause the complete disappearance of DRP evoked by a single volley of FRA. In these experiments spontaneous activity in the ventral roots usually occurred. Only exceptionally did spontaneous activity appear in the primary afferents, which could be registered only in muscle nerves but not in the cutaneous nerves.

In other cats the effect of amphetamine was not so outstanding and an increased dose of 6 mg/kg did not cause any spontaneous activity. Nevertheless, the depression of the DRP evoked by a single volley to FRA was a constant finding and in some experiments a long-latency response similar to that described after L-DOPA and 5-HTP[5] occurred.

It can be concluded that the effect of amphetamine on spinal reflexes is strikingly similar to that of L-DOPA and 5-HTP, which makes it probable that they affect the same interneuronal pathway in the spinal cord. Further facts are required to show whether amphetamine is a drug from which effective monoamine transmitters can be formed or whether it acts by stimulating the monoaminergic terminals inducing a higher release of the transmitter.

PHARMACOLOGY

Assay of Gonadotrophins by the Deciduoma Method

In this laboratory a method has been developed for measuring the luteotrophic activity of prolactin by the formation of deciduomata in a damaged uterine horn in the hypophysectomized adult mouse[1]. The decidual response was quantal and the percentage of positive responses was transformed into probits. The method was designed as a 4 or 6 point parallel line assay and results were expressed in terms of the 2nd International Standard Prolactin (ovine prolactin, Armour Lab., Lot No. *D* 14083–2*B*, potency 22 I.U./mg).

Human pituitary luteinizing hormone[2] (IRC_2 fraction, potency 1,440 units IRP-HMG/mg by the ovarian ascorbic acid depletion assay (95 per cent fiducial limits 710–2,500 units)) and human chorionic gonadotrophin (CG, Leo, batch No. 162041, 1,500 I.U./mg) induced deciduomata in this assay and their dose-response curves were similar to that of ovine prolactin. Results of assays are shown in Table 1. It will be noticed that both preparations were more active than the reference standard.

Chorionic gonadotrophin, 'Pregnyl' (Organon, commercial preparation, batch No. 9107), was also assayed by the same method and its potency was found to be 62 per cent (95 per cent fiducial limits 44–101) of that of CG Leo when compared in international units CG.

Table 1. Assay of Human Luteinizing Hormone and of Human Chorionic Gonadotrophin by the Deciduoma Assay

Preparation	Result (mg/mg standard with 95 per cent fiducial limits)	Index of precision (λ)
Human pituitary luteinizing hormone, IRC_2	6·92 (4·33–11·80)	0·11
Human chorionic gonadotrophin Leo, 162041	11·39 (6·07–19·31)	0·13

Pregnant mares' serum gonadotrophin ('Gestyl', Organon, Lot No. 9651, 400 units/ampoule) and an extract of the endometrial cup secretion of a pony were assayed by this method and were both found to induce the decidual reaction.

The relative potency of the endometrial cup secretion of the pony, expressed as mg/mg Standard, was 5·24 (95 per cent fiducial limits 2·86–20·96) and the index of precision, lambda, was 0·15. Serum gonadotrophin (PMS) induced the decidual response at 80 units and contained about 14 units of luteotrophic activity per ampoule.

This work was supported by a grant from Organon Laboratories, Ltd., the endometrial cup secretion was kindly supplied by Dr. R. V. Short, University of Cambridge, and the extract was prepared by Dr. W. R. Butt in this laboratory.

Metabolic Effects of Oxytocin in the Chicken

Oxytocin has been shown to have marked metabolic effects in several species of experimental animals. These effects can be elicited either by administration of exogenous material or by physiological stimuli inducing the secretion of oxytocin from the posterior pituitary gland. A marked species difference may be seen in the effects[1]. In the chicken the occurrence of the oxytocic principle in the hypophysis is established[2] but its physiological significance remains obscure, and the literature contains little concerning the metabolic effects of oxytocin in the chicken. Possible sex difference in the effects was also investigated, as it was recently noted that such difference occurred in the dog[3].

Adult leghorns of local breed were used in this study. After fasting overnight they were bound on the table, unanæsthetized, undisturbed for at least 1 h. Blood samples were obtained through a thin polyethylene tube inserted deep into the wing vein; two control samples and four or five further samples at 5, 10, 20, 40 and 60 min after intravenous administration of oxytocin ('Syntocinon', Sandoz). Blood samples were transferred to iced and heparinized tubes, then centrifuged. The plasma was separated without delay. Plasma glucose was determined by the glucose oxidase method[4] using 'Glucotest' (Boehringer and) plasma free fatty acids by Dole's technique[5].

Oxytocin caused transient but marked increase in the concentration of both glucose and free fatty acids. Glucose reached its maximum value at 10–20 min, whereas free fatty acid attained its peak at 5 or 10 min, that is, always ahead of glucose (Table 1).

Fig. 1 shows dose response curves obtained in the hen. The results are expressed as percentage increments over control levels, and the maximum changes after oxytocin injection were plotted against the log dose scale. Glucose shows 15 per cent increase with 20 mU/kg and slightly more

Table 1. Percentage Changes of Glucose and Free Fatty Acids (FFA) in Plasma after Intravenous Administration of 80 mU/kg Oxytocin (Mean values with the *S.E.* from 5 experiments)

		Control	Changes in percentage			
			5 min	10 min	20 min	40 min
Females (5)	Glucose	229 ± 8·5 (mg %)	+10·4 ± 1·9	+15·0 ± 2·8	+11·2 ± 4·1	+6·2 ± 3·3
	FFA	682 ± 110 (μequiv./l.)	+37·2 ± 9·0	+28·0 ± 6·8	+0·8 ± 3·1	−3·0 ± 9·2
Males (5)	Glucose	225 ± 10·7 (mg %)	+10·2 ± 2·0	+10·4 ± 2·1	+5·0 ± 2·2	+3·4 ± 2·4
	FFA	564 ± 53 (μequiv./l.)	+63·8 ± 10·1	+37·6 ± 11·7	+11·0 ± 9·6	−9·2 ± 3·1

with the increase of the dose, while the free fatty acid curve is steeper, attaining the maximum of about 40 per cent increase with the dose of 80 mU/kg.

Table 1 shows that there is no difference between the sexes either in the response or in the time course. Both cock and hen respond with hyperglycæmia and hyperlipæmia, which decline rapidly. Males show a more marked hyperlipæmia and slightly greater tendency toward a negative fluctuation at 40 min, though all the values are not significantly different from the corresponding values in the hen ($P > 0{\cdot}05$). By 60–90 min plasma levels of both glucose and free fatty acid returned to the pre-test levels. Qualitative differences in response in males and females were not observed (cf. Burt *et al.*[3]); the discrepancy may be due partly to the fact that they collected no sample before 30 min.

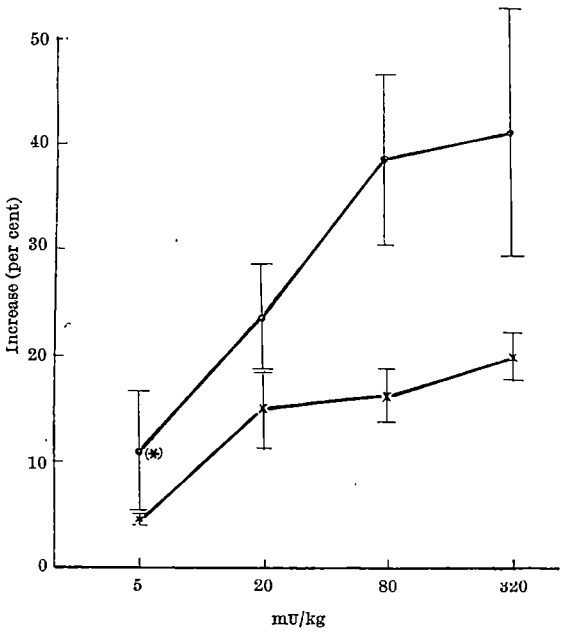

Fig. 1. Dose response curve of oxytocin in the hen. Maximum percentage increases over the pre-test level were plotted against the dose in mU/kg. ●, FFA, ×, glucose concentration in plasma. Each point denotes the mean from 5 hens with the standard error. All values are statistically significant except one (★)

The results of the study presented here are contrary to the findings in the dog, which exhibits marked hypolipæmia and hyperglycæmia when given oxytocin[1,7]. The similarity of its effect to that of epinephrine[5,6] suggests the possibility that endogenous catecholamines may play a part in the metabolic effects of oxytocin. However, in view of the fact that a small dose (5 mU/kg) elicits metabolic effects without any change in blood pressure, that larger doses evoke only transient hypotension without secondary hypertension, and taking into account the promptness of the response, it seems unlikely that the catecholamines are involved. Further evidence was observed in five reserpinized hens (10 mg in two divided doses in successive days and used on the next day) in which oxytocin elicited exactly the same response as in the untreated ones.

Whether these effects are due to increased release of glucose and free fatty acid from the store, or decreased utilization in the periphery, or both, is a matter of conjecture at present, and the biochemical mechanism of these actions, and the species differences, await further investigation.

Adrenal and Plasma Corticosteroids and Ascorbic Acid Content during Bone Fracture Healing

Adrenal cortical hormones play an important part in recovery from traumatic stress[1]. This applies to the healing of bone fractures, although cortisone and similar substances when given in large doses interfere with fracture healing[2]. These hormones are said to retard healing through inhibiting and delaying the absorption of blood clots, the formation of callus and the production of collagen[3]. Ascorbic acid has a beneficial action on adrenal cortical activity in relation to stress[4]. In addition, ascorbic acid is needed for the biosynthesis of collagen[5], which is indispensable for a normal healing process.

This investigation deals with the changes occurring in the levels of adrenal and plasma corticosteroids, and of vitamin C, at various times after experimental bone fracture. Special attention was directed to changes during the first week.

Ninety adult male white rats, weighing about 220 g, were used. Fractures of the left tibia were induced under ether anæsthesia[2]. Groups of animals were killed at intervals of 6, 12, 18 and 24 h, 2, 3, 4, 5, 6 and 7 days, and 2, 3 and 4 weeks afterwards. The blood of each animal was collected separately. Groups of normal animals served as controls. The adrenal glands were removed immediately after death, carefully cleaned of all superfluous tissue and weighed on a torsion balance to 0·1 mg. Ascorbic acid was extracted from the glands in glass homogenizers containing 10 ml. of 6 per cent trichloroacetic acid. The homogenate was centrifuged and ascorbic acid was determined in the clear supernatant fluid. Adrenal and plasma ascorbic acid were estimated using the dinitrophenylhydrazine method[6].

Adrenal glands for corticosterone estimation were homogenized and prepared according to the method of Guillemin *et al.*[7]. Plasma corticosterone was extracted and prepared as described by Zenker and Bernstein[8], using the modifica-

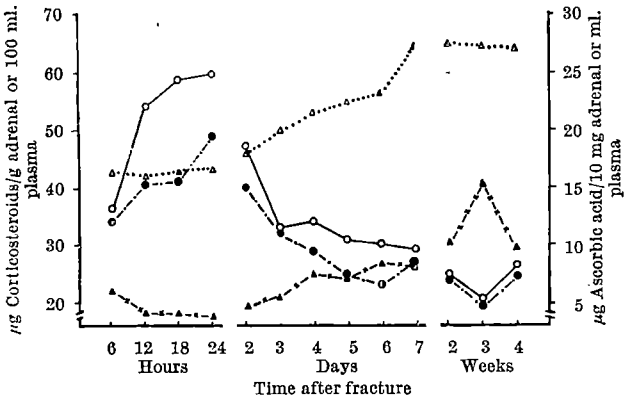

Fig. 1. Corticosteroid and ascorbic acid content of rat adrenal and plasma after tibial fracture; ○—○, adrenal corticosteroids; ●— · —●, plasma corticosteroids; △ . . . . △, adrenal ascorbic acid; ▲— × —▲, plasma ascorbic acid

tion of Dao, Flaxman and Lonergan[8] for the final development of fluorescence. Fluorescence was measured on Dr. Lange's universal colorimeter model *UK* VII equipped with a mercury lamp and two black glass filters slipped on the lens tube with two yellow light filters *GG*11 of 60 mm φ located directly in front of the cell.

The results are plotted graphically in Fig. 1. There was a statistically significant increase in the levels of adrenal and plasma corticosteroids, detected after 6 h, and increasing continuously to a maximum at the end of the first 24 h. The fact that plasma and adrenal steroids increased concomitantly suggests that the synthesis of corticosterone was increased[9]. Plasma and adrenal corticosteroids returned to normal levels after 4 and 6 days respectively.

It is generally accepted that bone resorption occurs at the fracture site before active regeneration leading to callus formation can occur[2]. Using ^{35}S it was possible to demonstrate that, by the end of the first week, the uptake of radioactive sodium by rats' humeri[10] and rats' tibiæ[2] was significantly decreased in the fractured bones compared with the normal bones of the same animals. The incorporation of radioactive sulphur is a measure of the formation of acid mucopolysaccharides which are essential constituents of bone ground substance. In addition, adrenal steroids interfere with cellular activity and depress mitosis[11]. Moreover, cortisol and cortisone were reported to inhibit fibroblastic production of collagen[12]. Clark and Roth[13] showed that the action of hydrocortisone on bone minerals is not mediated through the parathyroid gland but can be attributed to the anti-anabolic action of the hormone.

There was a negative correlation between the levels of adrenal corticosteroids and the ascorbic acid content of the adrenal glands. Although the relationship between ascorbic acid and adrenal steroid synthesis is not yet understood, it has been shown that exogenous ACTH further depressed the level of ascorbic acid in the adrenals of scorbutic animals[14].

Plasma ascorbic acid levels significantly decreased from normal values during the first three days after fracture. This observation is in agreement with the finding of Andreae and Browne[15], who demonstrated a markedly increased catabolism of ascorbic acid in human beings after burns and fractures.

There was no correlation between plasma and adrenal contents of vitamin C. However, there was a significant decrease in the level of adrenal corticosteroids accompanied by a significant increase in the level of plasma ascorbic acid for the values recorded at the end of the third week. An increased level of ascorbic acid favours increased collagen biosynthesis[5]. This is also true during fracture healing since it has been previously shown that maximum production and maturation of callus cellular elements took place during the third week[2].

Finally, the results show that, in rats with experimental fractures, there is a stage of increased suprarenal activity which attains a peak in 24 h, and thereafter declines steadily to normal levels before the end of the first week. The synthesis of ascorbic acid reached its maximum during the third week after the fracture, and this coincides with the period of maximum production and maturation of collagen fibres.

Exaltation of Toxicity of Sympathomimetic Amines by Thyroxine

Various factors are known to influence the toxicity of sympathomimetic amines in mice, especially ambient temperature[1,2], aggregation[1,2] and psychotropic drugs[2–5]. Halpern *et al.*[6] reported recently that pretreatment with thyroxine considerably aggravated the central nervous stimulation and mortality induced by amphetamine in aggregated mice. Here, evidence is presented to show that pretreatment with thyroid hormone also markedly increased the toxicity of sympathomimetic amines in solitary mice.

Adult 'Swiss' male mice were used, weighing between 20–22 g, obtained from a single breeder. DL-thyroxine was injected intraperitoneally in daily doses of either 200 μg/kg or of 1 mg/kg. DL-amphetamine (sulphate) and ephedrine (hydrochloride) were also injected intraperitoneally in doses and at times after the beginning of thyroxine treatment as indicated in Tables 1 and 2. Throughout the whole experiment, the animals were kept in a room at a constant temperature of 27° ± 1° C. Immediately after the injection of the sympathomimetic amines, the animals were placed in a glass jar (220 mm diameter) divided into equal compartments by an opaque device, each animal occupying an individual compartment in order to avoid the interference of the aggregation phenomenon. The behaviour of the animals was carefully observed and the mortality recorded during the following 24 h.

The results are summarized in Tables 1 and 2. The data reported in these tables suggest the following considerations: Thyroxine considerably enhanced the toxicity of both the sympathomimetic amines studied here. Halpern *et al.* have recently shown that similar enhancement of toxicity by thyroxine was observed with other sympathomimetic substances[7].

The ratio $\frac{\text{toxicity control 60 per cent}}{\text{toxicity } T_4 \text{ 60 per cent}}$ reached a reciprocal value between 15 and 20, which was considerable. There have been few, if any, reported cases in which the

toxicity of a pharmacological agent was increased to such a degree by the administration of a hormone.

The development and the degree of enhancement of the toxicity of the sympathomimetic amines by the thyroid hormone depended on the dose and on the duration of the hormonal treatment. With doses of thyroxine of 1 mg and above, enhancement of toxicity was evident several hours after the injection. The phenomenon increased in intensity as the treatment was repeated and reached a maximum after 3–5 days of treatment. The results were similar for amphetamine and ephedrine. With doses of thyroxine of 200 μg/kg, the effect was similar but less marked. As this phenomenon was demonstrated in isolated mice, we can admit that thyroxine affected some critical mechanisms which were directly implicated in the death of the animal. What may these mechanisms be? The main property of amphetamine and of other drugs belonging to this group is the induction of central and peripheral sympathetic stimulation. According to present views, these effects are likely to be related to the release of catecholamines. It has been recently shown[8] in this laboratory that, in aggregated mice, emotional stress was accompanied by a considerable depletion of brain catecholamines. Moreover, evidence has been furnished that tyramine and other indirect sympathomimetic amines determined a release of noradrenaline from the vascular walls[4]. That the impairment of endogenous catecholamine metabolism may have been directly related to the toxicity of the amines studied here was supported by the recent observation in this laboratory that administration of IMAO equally potentiated the toxicity of amphetamine, ephedrine, etc.

On the other hand, IMAO as well as thyroxine has been shown recently by Halpern *et al.*[9] to be able to annul the protective effect exerted by reserpine against the 'group toxicity' induced by amphetamine in aggregated mice. This similarity of action of IMAO and thyroxine in both circumstances suggests a similar mechanism, which may have been central or peripheral. These problems, the importance of which we wish to emphasize, are now under investigation. The mortality among mice treated with thyroxine and sympathomimetic amines was due to an extensive myocardial necrosis. These observations may also be relevant to the mechanisms by which thyroxine enhanced the toxicity of sympathomimetic amines. Finally we wish to emphasize the potential danger of administering sympathomimetic amines to patients with hyperthyrea, and of drugs associating thyroxine with sympathomimetic agents, as the toxicity has been enhanced by doses which are near the therapeutic range.

PATHOLOGY

An Unidentified Compound in the Serum of Children with Kwashiorkor (Protein–Calorie Malnutrition)

When using the rapid chromatographic method recently developed for measuring the balance of amino-acids in the serum of children with kwashiorkor[1] we have found an unidentifiable compound with an R_F value slightly less than that of valine. The solvent used was *A* in Table 1. This communication describes various properties of the compound and the conditions under which it can be demonstrated.

Table 1. R_F values on No. 20 Whatman paper of the unidentified serum compound in kwashiorkor and of piperidine-2-carboxylic acid

	Solvent				
	A	*B*	*C*	*D*	*E*
Piperidine-2-carboxylic acid (authentic)	0·44	0·88	0·45	0·41	0·51
Unidentified compound	0·45	0·86	0·45	0·40	0·50
Co-chromatography	0·45	0·86	0·44	0·40	0·50
Piperidine-2-carboxylic acid (ref. 3)	0·44	0·93	0·45	0·41	—

The solvents were: *A*, butan-1-ol–acetic acid–water (12 : 3 : 5, by vol.); *B*, phenol–water (500 g, 125 ml.); *C*, butan-1-ol–pyridine–water (1 : 1 : 1, by vol.); *D*, ethanol–ammonia–water (18 : 1 : 1, by vol.); *E*, butan-1-ol–water–formic acid (7 : 2 : 1, by vol.).

Unlike the amino-acids that are eluted and estimated for the balance method, the compound did not react with ninhydrin in the cold. On heating to 120° C, however, a purple colour was produced that was more blue than the colour usually formed by amino-acids. The ninhydrin derivative had two unusual properties. In ultra-violet light it had a cherry-red fluorescence, unlike the derivatives of amino-acids, which absorb ultra-violet light and appear black. When the chromatogram was dipped through a solution of ethanolic copper nitrate the colour did not change to the typical pinkish-orange but remained blue-purple. A compound with these properties has been described; it is piperidine-2-carboxylic acid (pipecolic acid)[2,3], a derivative of lysine. The unknown compound gave a strong blue-green reaction with isatin, indicating a relationship to pyrrolidine or piperidine derivatives[4].

Deproteinized samples of serum were prepared and applied without de-salting to Whatman No. 20 paper as previously described[1]. The chromatographic properties of the compound were compared in five solvents with those of a sample of authentic piperidine-2-carboxylic acid obtained from the California Corporation for Biochemical Research, Los Angeles. The results are recorded in Table 1. Colour reactions of the unknown and the known substances agreed closely, and co-chromatography in each of the solvents failed to separate them. The solvent systems used will separate piperidine-2-carboxylic acid from piperidine-3-carboxylic acid, piperidine-4-carboxylic acid, piperidine-2,6-dicarboxylic acid and 5-hydroxy-piperidine-2-carboxylic acid[5].

The unidentified compound is not found in all samples of serum taken from children admitted for the treatment of kwashiorkor. There appears to be no correlation between the presence or absence of the compound and the severity of the kwashiorkor on admission. After a meal containing protein or after a dose of *l*-lysine, it is very often demonstrable. When treatment is proceeding favourably, the compound slowly disappears from the serum and none can be detected after about 10 days. In less favourable circumstances, especially when the concentration of the total serum proteins does not rise satisfactorily, the amino-acid balance ratio rises and the weight gain is poor, the amount of the compound appears to increase even beyond the level found on admission.

Disturbances in the metabolism of histidine, phenylalanine and tyrosine in kwashiorkor have already been described[6,7]. The present finding demonstrates the abnormal metabolism of an additional nitrogenous compound. Confirmation of our tentative identification of the compound as piperidine-2-carboxylic acid would indicate that the metabolism of lysine is at fault.

We have at present no definite information about the source of the unknown compound. It is unlikely to be merely a component of the diet, since it is found in samples of blood taken after an overnight fast, and does not increase in amount towards the end of successful treatment in pace with the improvement of the child's appetite and food intake. The rise in serum concentration after milk protein or lysine has been given suggests, but does not prove, that the source is an amino-acid.

The structure of piperidine-2-carboxylic acid closely resembles that of the amino-acid proline and the vitamin nicotinic acid, and it is possible that the raised concentration of piperidine-2-carboxylic acid in the serum may affect the metabolism of these two substances.

Samples of serum containing the unknown compound are being collected for an elementary analysis and the determination of molecular weight. The collection will take a very long time, because only a small amount of blood can justifiably be taken from the severely ill children in whose serum the compound appears. It is hoped that the publication of this report will encourage other workers to look for the compound. It may have been confused with β-aminoisobutyric acid or ethanolamine, both of which have been reported in the serum in kwashiorkor. The ninhydrin derivatives of these compounds do not fluoresce in ultra-violet light; they give the normal orange colour in ethanolic copper nitrate.

Influence of Diet and Iodine-131 Injections on the Survival of Dystrophic Mice

Diet has been shown to influence the survival of mice with hereditary muscular dystrophy, since an increased lifespan and an extended period of growth have been recorded when a semi-synthetic diet containing high-quality protein and lipid was used, and the further addition of glycine to the diet increased the growth rate still more[1]. Apparently, the vitamin content of the diet did not produce the effect, since other investigations using massive doses of vitamin mixtures did not prolong the survival of dystrophic mice[2]. Suppression of the thyroid gland activity by ^{131}I (ref. 3), or surgical removal of the gland[4], delayed muscular degeneration in vitamin E-deficient rabbits, indicating an influence of the thyroid hormone on this type of muscle pathology.

Mice with hereditary muscular dystrophy (*dydy*) were obtained by mating *Jax*/129 (*Dydy*) mice from the Jackson Memorial Laboratory, Bar Harbor, Maine, and were maintained in temperature-controlled quarters. Food and water were available *ad libitum*. Mice were weaned at 3–4 weeks, experimental groups were formed by dividing litters, and treatments were initiated at weaning. During the first trial, the diet consisted of 'Purina Laboratory Chow', and treated mice were given a single intraperitoneal injection of 200 mc. ^{131}I as sodium iodide in a small amount of physiological saline at three weeks of age.

During the second trial, the semi-purified diet (Table 1) contained 2 levels of sodium and potassium, and some of the mice were given a combination of the higher sodium level diet, ^{131}I injection as in the first trial, and 5 mg of 17-α-methylandrostene-5-diol-3β-17β-dienanthoylacetate (MADD) in sesame oil in a weekly intramuscular injection, the dose being equivalent to the methylandrostenediol.

Table 1. Composition of the 'Semi-purified' Mouse Diet

Item	Per cent
Vitamin-free casein	40·00
Alphacel (non-nutritive bulk)	3·00
Corn starch	12·00
Sucrose	12·55
Dextrose	12·00
Briggs salt mixture[7]	6·00
Vitamin-free lard	10·00
Potassium acetate	2·50
Magnesium oxide	0·50
Choline chloride	0·30
Inositol	0·40
Ascorbic acid	0·50
p-Amino benzoic acid	0·25
Complete vitamin supplement[8]	—

The diet was mixed in portions sufficient for 5 days and kept under refrigeration to minimize deterioration. In the lower sodium diet, KCl was substituted for NaCl. The higher sodium diet contained 0·583 per cent sodium and 0·400 per cent K, while the lower sodium diet contained 0·237 per cent sodium and 1·862 per cent K.

In the first trial using the laboratory chow (Table 2), the ^{131}I injection prolonged the survival of dystrophic mice approximately two-fold and may have slightly retarded the growth rate of the normal littermates. In the second trial using the semi-purified high protein rations (Table 2), the sodium and potassium levels did not influence survival, but a three-fold increase was noted in dystrophic mice on this diet as compared with those in the first trial receiving the laboratory chow. The growth rate of the normal littermates was retarded by the semi-purified ration. Some benefit from the lower sodium level in the diet might have been expected, since the sodium level of dystrophic mouse muscle is 50 per cent higher than normal[5]. Dystrophic mice receiving the higher sodium level semi-purified diet with injections of ^{131}I and MADD did not survive as long as those receiving the semi-purified diet alone, indicating that the benefits of these treatments were not additive. MADD has previously been shown to prolong the survival of dystrophic mice two-fold[6]. The treatments did not appear to alter the disease syndrome in other ways; both histologically and by gross observation, the pathological processes were similar in all groups.

Table 2. Survival of Dystrophic Mice

Condition and treatment	No. mice	Median survival time and range (weeks)	Av. body-weight (g) at weeks: 3	10–20	20–30	30–40
First trial (commercial pellets)						
Normal						
Males	78	—	10	30	34	33
Females	70	—	9	27	31	31
Normal ^{131}I Inj.						
Males	41	—	10	27	31	33
Females	35	—	10	27	29	28
Dystrophic						
Males	8	6 (4–11)	6	19	—	—
Females	13	8 (4–25)	6	18	18	—
Dystrophic ^{131}I Inj.						
Males	15	14 (9–20)	5	20	21	—
Females	18	18 (7–43)	6	16	17	15
Second trial (semi-purified high-protein diet)						
Normal, Higher Na						
Males	64	—	9	25	29	32
Females	58	—	10	21	26	30
Normal, Lower Na						
Males	48	—	11	23	29	31
Females	44	—	10	21	26	30
Dystrophic, Higher Na						
Males	12	21 (13–28)	6	15	16	—
Females	12	22 (4–26)	7	13	15	—
Dystrophic, Lower Na						
Males	16	22 (7–31)	7	15	13	13
Females	18	20 (8–30)	8	13	13	—
Normal, Higher Na, ^{131}I Inj. and MADD						
Males	12	—	9	25	29	29
Females	12	—	10	21	25	24
Dystrophic, Higher Na, ^{131}I Inj. and MADD						
Males	10	15 (4–34)	7	16	17	16
Females	8	17 (10–22)	6	14	15	—

In summary, the survival of dystrophic mice receiving a commercial laboratory diet was about doubled by the injection of ^{131}I at 3 weeks. A high-protein semi-purified diet prolonged survival approximately three-fold. The level of sodium and potassium in the high-protein semi-purified diet, however, did not influence survival, and a combination of ^{131}I injection, weekly injections of methylandrostenediol dienanthoylacetate and the high-protein semi-purified diet did not prolong survival beyond the time observed with the high-protein semi-purified diet alone. None of the treatments affected the characteristics of the syndrome in any other way.

This work was supported in part by a U.S. Public Health Service research grant, *A*–4273, from the National Institute of Arthritis and Metabolic Diseases. The ethylandroste nedi ol dienanthoylacetate was given by the S. E. Massengill Co., Bristol, Tennessee.

Intravital Fluorescence Microscopy in the Qualitative Evaluation of the Interaction of Acridine Orange with Nucleic Acid in Intact Living Human Organs*

Observations on living organs excited by ultra-violet irradiations have been almost entirely confined to work on experimental animals. The specific fluorescence method was largely developed through the work of Ellinger and Hirt[1,2], who termed it intravital fluorescence microscopy. The method found use in the investigation of resorptive and excretory functions of different organs, and offered valuable information about the physico-chemical conditions and processes in living cells, in particular the electrostatic phenomena. It also helped in the elucidation of various problems concerning the function of kidneys[3,4], liver[5,6], blood vessels[7], and nerves[8], and other organs of experimental animals.

Although the method proved most valuable, yielding specific information concerning the behaviour of living cells and tissues with minimal interference with their normal physiology[9], and identifying minute concentrations of administered dyes in different tissues[5], no attempt has been reported to apply it widely in the investigation of human biology. One reason is, no doubt, the technical difficulties inherent in the construction and adaptation of the instrument.

In previous investigations[10–12], I demonstrated the affinity of the basic dye acridine orange (3,6-*bis* dimethylaminoacridine) for the nucleic acids of intact human cells and tissues; it forms monomeric, dimeric or polymeric dye complexes[13] within normal, malignant and devitalized tissues, respectively. Identification of tissues by virtue of their differential fluorescence spectra was described, and suggested as the basis for a new clinical cancer test[10–12].

The aim of the present communication is to describe the principles fulfilled in construction of an intravital fluoromicroscopic unit for the excitation and inspection of living human organs fluorochromed with acridine orange, to evaluate the qualitative variations in the interaction of the dye with the nucleic acids of living tissues.

* This communication is a part of an investigation on "A New Cancer Test" awarded the Edgar-Gentilli Prizes for the year 1962–63 by the Royal College of Obstetricians and Gynaecologists.

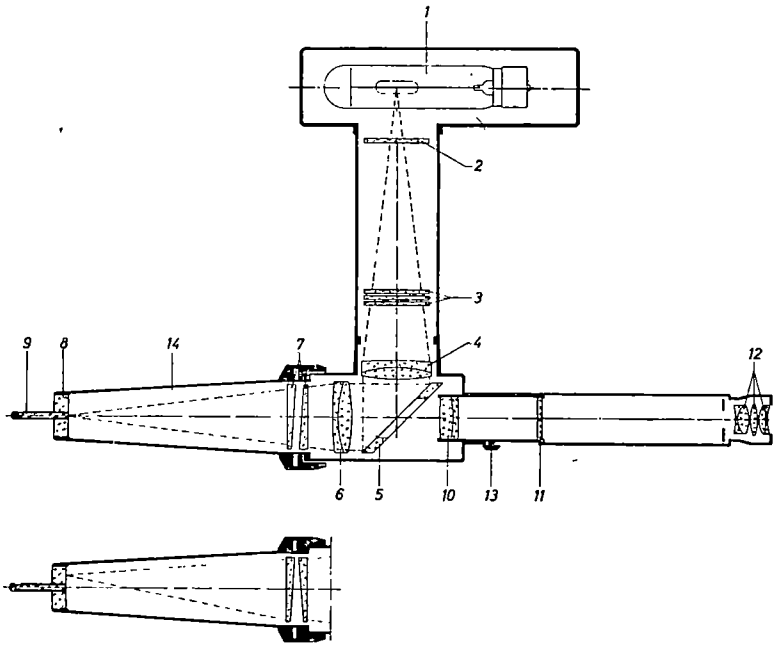

Fig. 1. The design of a fluoro-microscopic unit (the 'Cervicoscope') intended for the examination of the human cervix uteri

An instrument has been constructed (Fig. 1) for the examination of the human cervix†, but the principles are applicable to the design of instruments for the examination of other accessible organs. Incident illumination was used, the ultra-violet beam entering the main tube through a side-arm, to be deflected down to the objectives (Fig. 1, 8 and 9).

To avoid restriction of the objective aperture by the use of a prism or mirror to deflect the beam through 90°, as originally suggested by Ellinger and Hirt[1,2], a dichroic reflector with high ultra-violet reflectance and high transmission of ordinary light was used[5]. This increased the brightness of the image, which is known to vary with $(N.A.)_0^2/M$, where $(N.A.)_0$ is the numerical aperture of the objective, and M is the total magnification of objective and occular combined.

Further increase in image brightness was achieved by using an overall magnification of × 17, reducing to a minimum the distance between source and object, and illuminating a relatively small field with a condenser of higher numerical aperture. According to the fluorometric law of De Ment[14], the fluorescence intensity is proportional to the intensity of the optical excitant over wide ranges, and varies inversely as the square of the distance from the source of irradiation. In the living body, however, possible injury to cell membranes limits undue increase in the source intensity, hence this was kept within the safe range of 150–200 W, supplied by a high-pressure mercury vapour lamp with a specially constructed housing (Fig. 1, 1).

Since the area of the irradiated field at the object is equal to $A\ (N.A.)_s^2/(N.A.)_c^2$, where A is the effective source area, while $N.A._s$ is the numerical aperture of the lamp lens and $N.A._c$ is the numerical aperture of the condenser, it would have been possible to fill a large field by reducing the condenser aperture (Fig. 1, 4). This, however, would reduce the image brightness since the intensity of irradiation is proportional to $B\ (N.A.)_c^2$, where B is the image brightness. Therefore, it was preferable to illuminate a small field and obtain high image brightness by increasing the numerical aperture of the condenser. An alternative system is to fill a larger field by using a light source of large area and a lamp lens of high relative aperture.

To utilize a cross-filter system for excitation and inspection of the fluorescence of acridine orange, which is known to absorb in the region of 4000–4500 Å, a primary filter which cuts out all wave-lengths below 4000 Å was mounted between the lamp lens and the condenser (Fig. 1, 3), protected from the ultra-violet source by heat-resistant filter (2). The secondary filter (11), which cuts out all blue-violet rays (4000–4500 Å), was mounted between the objectives and ocular (12). This limits the fluorescence image to the green, yellow and red, which are the colours of monomeric, dimeric and polymeric acridine–nucleic acid complexes, respectively.

To avoid reflexion loss, the excitation rays are delivered to the object through a metal tube (14), and the fluorescence rays are afterwards transmitted back from the object to the ocular (12). An additional factor in image brightness was the use of a monocular unit, since the brightness is known to be reduced with a factor of more than 2 in all minocular fluorescence microscopes. The wedges (7) and button (13) are mechanical devices, respectively, for the illumination of successive fields and for focusing the fluorescence image.

IMMUNOLOGY

Type of Antibody Response in Mice immunized with Transplantable Tumours

Antibody in the serum of several animal species is confined to two main classes of proteins with sedimentation coefficients of approximately 7*S* and 19*S* respectively. The former class comprises molecules with molecular weights of at least 150,000 and includes both the 7*S*γ-globulins and the β_{2A}-globulins. The latter class is made up of β_2-macroglobulins with molecular weights of about 1,000,000. The type of antibody response appears to depend on a number of interrelated factors, probably the most important of which is the physicochemical nature of the stimulating antigen. Thus hæmocyanin[1], *A*2 influenza virus[2], and type III pneumococcal polysaccharide[1] were found to produce 7*S*γ-globulin, while sheep erythrocytes produced predominantly β_2-macroglobulins[1].

Various transplantable plasma cell tumours[3,4] and leukæmias[5] in mice have been described in the literature in recent years. Their availability has allowed a new approach to the study of malignant plasma cells and their effect on the serum protein systems in experimental animals.

An attempt has been made to follow the changes in the mouse γ-globulin system resulting from immunization with transplantable tumours by the use of analytical ultracentrifuge and gel-filtration techniques.

Mouse strains *A*, *C*, *C3H* and *C57BL* were used for these experiments. The transplantable mouse tumours comprised two mouse leukæmias, *AL3* and *EL4*, and two solid tumours, *AMT3* and *EP6*. The original tumours were kindly supplied by Dr. J. R. Batchelor, Guy's Hospital Medical School, London.

Batches of 20–100 mice of each strain were immunized with three injections of each of the heterologous tumours. The first inoculum of approximately 5 million viable cells was given subcutaneously. The second and third injections of approximately 50–100 million cells were given intraperitoneally 4 weeks and 6 weeks respectively after the first inoculum.

Serum was obtained from the mice immediately prior to each successive immunization by bleeding the animals from the tail vein[6]. The mice were finally bled two weeks after receiving the last injection.

Hyperimmune sera from a batch of hybrid mice, designated *PH* mice, and from 129 mice, both immunized with *BP8* tumour, were also kindly provided for examination by Dr. J. R. Batchelor.

The degree of the serum antibody response, as measured by the hæmagglutinating activity against mouse red cells[7], varied considerably in the initial stages depending on the mouse strain and on the tumour type. After the final immunization, the hæmagglutination titres were all of the same order.

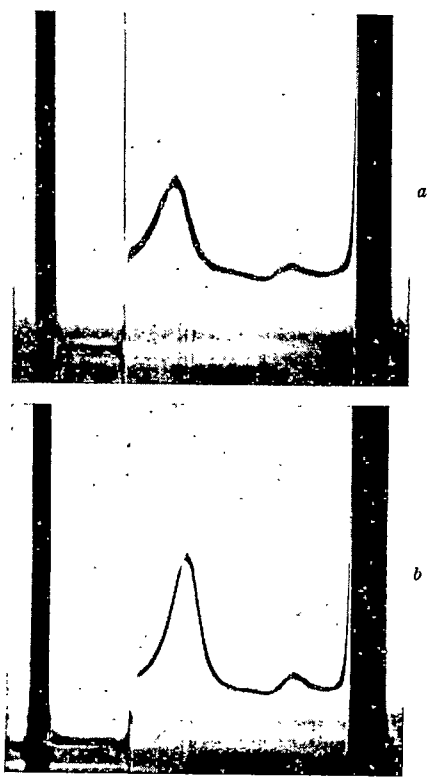

Fig. 1. Schlieren patterns obtained from sedimentation velocity experiments with mouse globulin preparations in the Spinco model *E* analytical ultracentrifuge. Speed, 42,040 r.p.m.; temperature, 20·0° C; photographs taken 52 min after reaching set speed. (*a*) Solution of normal globulins, phase plate angle, 40°; (*b*) solution of immune globulins, phase plate angle, 50°

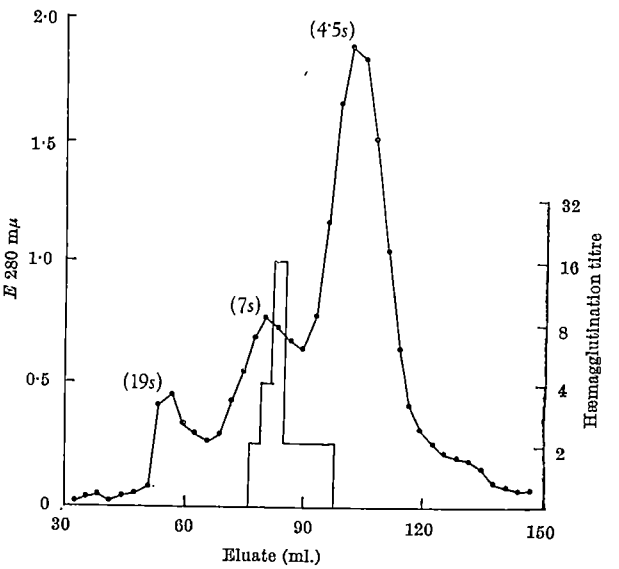

Fig. 2. Gel-filtration of mouse anti-tumour serum on 'Sephadex *G*-200' showing the distribution of antibody activity (open block) related to the eluted protein peaks

Equal volumes of these sera, from which most of the albumin had been removed by fractionation with sodium sulphate, were dialysed against 0·1 M *tris*-hydrochloric acid buffer, *p*H 7·4, in 0·2 M saline, and then restored to equal volumes. These protein solutions were centrifuged at 42,040 r.p.m. in a Spinco model *E* analytical ultracentrifuge operated at 20·0° C. No change in area of the faster sedimenting peak (19*S*) was observed in the Schlieren patterns of the immune sera as compared with the normal sera. However, the area of the slower sedimenting peak, identified as the 7*S* component and which had a sedimentation coefficient of 5*S* under these experimental conditions, was significantly increased in all the hyperimmune sera. This indicates an increase in the relative concentration of the 7*S* component following immunization (Fig. 1).

Samples of serum obtained from the mice 2 weeks after the final immunization were subjected to gel filtration on 50 × 1·8 cm. 'Sephadex *G*-200' (Pharmacia, G.B.) columns. In some cases most of the albumin was removed from the sera by fractionation with sodium sulphate in order to allow greater amounts of the mouse globulins to be loaded on to the columns. 0·1 M *tris*-hydrochloric acid buffer, *p*H 7·4 in 0·2 M sodium chloride, was used to elute the proteins from these columns.

The extinction at 280 mμ and the hæmagglutination activity of the eluted column fractions were measured (Fig. 2). The principal peaks eluted from the column were identified as 19*S*, 7*S* and 4·5*S* proteins in the analytical ultracentrifuge. The proteins contained in these broad zones were further identified by starch-gel electrophoresis. Hæmagglutinating activity was exclusively confined to the 7*S* proteins in all the immune sera examined.

The immune γ-globulin could be isolated by DEAE-cellulose chromatography of the mouse globulin fraction. This γ-globulin was identified by starch-gel electrophoresis and by its behaviour on sedimentation velocity analysis.

These results may be summarized as follows. As judged by hæmagglutinating activity and ultracentrifuge analysis, no evidence was found for the presence of 19*S* serum antibody during the course of immunization of several strains of mice with five heterologous transplantable mouse tumours.

This work has formed the basis for a detailed investigation in mice of the immune response to tumours[8,9]. It was supported by the Cowburn research fellowship,

King's College Hospital Medical School (D. E. H. T.), and by grants from the British Empire Cancer Campaign for Research (J. W. and M. W.).

One of us (D. B. G.) is indebted to the Medical Research Council for providing the analytical ultracentrifuge.

Observations on Induction of Resistance to Rous Sarcoma Cell Antigens in Hamsters

It has recently been shown that inoculation of mice and hamsters with several oncogenic viruses (polyoma, *SV* 40, myeloid and lymphoid mouse leukæmia) makes them resistant to subsequent transplantation of tumour cells induced by the same virus. Our observations on chickens naturally resistant to the Rous sarcoma virus, or chickens with regressed tumours, suggested that in some instances it was possible to induce resistance to Rous sarcoma cell antigens in chickens. If this were true then the Rous sarcoma is not basically different from the polyoma and other virus tumours. However, certain characteristics of the processes induced by Rous virus (the susceptibility of the adult chicken to this virus, the permanent presence of the virus in tumour cells, the short latent period of tumour induction) make it very difficult to investigate resistance to this tumour cell antigen in its natural host—the chicken. Therefore, it was interesting to investigate the possibility of inducing resistance to the Rous sarcoma cells in a mammal.

Sjögren and Jonsson[8] immunized mice with the Rous sarcoma virus (Schmidt–Ruppin strain) and inoculated the immunized and control animals 5–10 days later with a cell suspension of Rous sarcoma grown on isologous mice. This induced a very weak resistance in virus-immunized mice.

In our experiments adult golden hamsters were inoculated with Rous sarcoma virus (Carr strain). The tumour extract prepared on 0·1 M phosphate citrate buffer was centrifuged at 5,000 r.p.m. for 20 min and the supernatant was stored in sealed glass ampoules at −70° C. The oncogenic virus activity was tested by intracutaneous inoculation of chickens. The supernatant had a virus titre of 10^{-5}/ml. to 10^{-6}/ml. The hamsters were inoculated with the Rous virus 2–3 times. They received every day 1 ml. of the supernatant intraperitoneally and 2–3 ml. subcutaneously. After 7–24 days the immunized hamsters and controls (intact, or immunized with normal hen embryo tissues) were inoculated with sarcoma cell suspension. This tumour was first induced by Rous sarcoma virus (Carr strain) in new-born hamsters and then passaged with cells in adult animals of this species[6]. The cells were suspended in Earle's solution (pH ~8) and counted before inoculation. Each hamster was inoculated with $4{\cdot}5 \times 10^3$ to $4{\cdot}5 \times 10^6$ cells subcutaneously. The animals were observed 2 months after tumour grafting. The tumours were palpated every 2–3 days. The hamsters surviving at the end of the experiment were killed. All animals were autopsied. The results of three experiments are summarized in Table 1.

Table 1. Inoculation of Immunized and Control Hamsters with Tumour Cells

	No. cells in inoculum				Log
	$4{\cdot}5 \times 10^3$	$4{\cdot}5 \times 10^4$	$4{\cdot}5 \times 10^5$	$4{\cdot}5 \times 10^6$	TD_{50}
Immunized	0/27*	4/27 (14·8%)	8/27 (29·6%)	24/27 (88·8%)	5·3
Control	0/22	9/22 (40·9%)	18/22 (81·8%)	22/22 (100%)	4·3

* Figures in the body of the table denote number of hamsters with tumours over total number inoculated. Log TD_{50} denotes log of the cell dose giving 50 per cent positive takes in inoculated hamsters.

These results show that immunization of adult hamsters with Rous sarcoma virus induced some degree of resistance to the sarcoma cell antigens. However, the resistance in this case is not so strong as in the experiments with polyoma or murine leukæmia virus[1–5]. Further experiments are needed to test the specificity of transplantation resistance for Rous tumour and to elucidate the nature of the induced 'new cell antigen'.

Diagnosis of Auto-immunity

In 1905 Osborne, Mendel and Harris[1] found that the extracts of certain beans had the capacity of agglutinating red blood cells. In 1949 Li and Osgood[2] used the extract of red beans in separating leucocytes from erythrocytes. Rigas and Osgood[3] described a method for the purification of phytohæmagglutinin. This method has been used by Difco Laboratories (Detroit) in preparing this material.

In 1959 Hungerford *et al.*[4] discovered that phytohæmagglutinin has a remarkable ability to initiate mitosis in cultures of leucocytes. Since then it has been extensively used in laboratories engaged in chromosome preparation. The nature of this mitogenic action was obscure until Hastings *et al.*[5] noted that phytohæmagglutinin had a leucoagglutinating activity. Rendon[6], using ^{14}C-labelled amino-acids, demonstrated that the leucocytes in tissue cultures produce a protein which migrates electrophoretically as γ-globulin. It produces fluorescent staining of all cells when incubated with fluorescent anti-γ-globulin. He concluded that the mitogenic action is probably an immune reaction.

This was followed by Pearmain *et al.*[7], who were able to produce mitosis in the lymphocytes from tuberculin-sensitive individuals by adding purified tuberculin to the cultures. Hirschhorn and his colleagues[8] produced the same effect in lymphocytes from individuals sensitized to diphtheria toxoid, pertussis vaccine and penicillin, using the appropriate antigen[3]. Not only microbial antigen but also tissue antigens have been used. Hashem *et al.*[9] found that lymphocytes from patients with infantile eczema were stimulated to undergo mitosis by extracts of human skin.

It seems that the technique of inducing mitosis appears to provide a useful and sensitive method for studying the mechanism of histo-compatibility. This communication describes a simple method which can be used to diagnose auto-immune diseases which have been attributed to release of previously sequestrated antigen (for example,

thyroiditis). This method is derived from the techniques described by Moorhead *et al.*[10], Edwards and Young[11], and Hashem *et al.*[9].

10 ml. of blood is obtained in a sterile heparinized container and left to sediment for ½–2 h. The supernatant layer (buffy coat) is aspirated in a Pasteur pipette and transferred to a sterile bottle. After mild shaking to disperse the cells evenly throughout the fluid, it is divided into three equal parts and put into three sterile universal containers. 'Medium 199' (Glaxo) containing antibiotics is added to each container to make a dilution of 1 part buffy coat to 3 parts of medium. 0·5 ml. of the antigen to be tested is added to the first bottle, an equal amount of phytohæmagglutinin to the second bottle, and of saline to the third bottle. The cells are incubated for 72 h. The slides are prepared as described by Moorhead *et al.*[10]. The results are read by scoring the percentage of dividing cells to non-dividing cells, and comparing the results obtained from the three bottles.

A high percentage of mitoses with antigen and with phytohæmagglutinin, and none with saline, suggests that the patient's symptoms are due to antigen–antibody reaction. A low percentage with antigen, a high percentage with phytohæmagglutinin, and none with saline suggest that there is no antigen–antibody reaction.

RADIOBIOLOGY

Early Response of *Pinus thunbergii* to Acute γ-Irradiation

While recently there has been much emphasis placed on the examination of the effects of chronic irradiation on intact whole forest ecosystems, the response of individual forest species following acute irradiation has received much less attention. At present only a limited amount of information is available concerning the effects of acute irradiation on the genus *Pinus*. Working at Brookhaven, Sparrow *et al.* have reported on *Pinus strobus*[1], and a second group under Shields has reported on *Pinus monophylla*[2]. The purpose of the work recorded here was to examine the response of *Pinus thunbergii* seedlings to acute γ-radiation under controlled laboratory conditions as opposed to that under the field conditions as examined by other workers[1,2].

One hundred four-year-old seedlings potted in 1-gal. metal cans were obtained from a local commercial nursery. The irradiation dose to be administered was chosen on the basis of Sparrow's work on *Pinus strobus*[1]. One half of the trees were irradiated while in the dormant state on February 21 of this year by means of a 10,000-c. cobalt-60 γ-source. Prior to irradiation the branches of each tree were bundled together loosely about the trunk in order to ensure as uniform a dose as possible to the entire tree. The time of exposure was 21·5 min. The total dose received by the trees was determined to be 715 ± 40 r by means of individual chemical dosimeters attached randomly to each tree. Afterwards, the trees were placed in the glasshouse and arranged in such a manner as to ensure that control and irradiated trees were randomly distributed.

In order that the effects of irradiation on growth of *Pinus thunbergii* be clearly understood, a short description of the normal growth of the plant is given. Longitudinal growth in this species is usually confined to candles laid down in the previous growth period. Development of adventitious buds is rare except in the case of physical injury to the plant, in which case such buds will develop from needle groupings in the area of the stem proximal to the injury. New shoots, or candles, which are laid down in the late summer and the autumn, may vary in length from 1 to 10 cm. Fig. 1 (left) illustrates the normal appearance of dormant candles. Following several months of winter dormancy, growth in the spring begins with the initial elongation of the candle occurring near its base. The zone of elongation then proceeds upwards toward the tip, with the portion of the shoot which has not yet begun to grow being literally lifted up by the elongating tissue beneath it. Such elongation continues, with the new needles being formed about the sides of the newly formed stem, until the zone of elongation reaches the tip of the previous year's meristem, at which time buds are laid down which will develop into candles for the following growth season. Fig. 1 (right) illustrates a group of normal candles in varying stages of development.

Measurements of the length of terminal and selected lateral candles on each tree were made during the first week following irradiation and before any visible growth was evident. In the second week following irradiation, elongation of the candles was evident in the control but not in the irradiated plants. Measurements of candle length were made in the third and sixth weeks on control and irradiated trees selected at random. In the third week the terminal candles of the controls showed an average growth of 3·6 ± 2·1 cm for 16 plants; the lateral candles a growth of 1·1 ± 0·9 cm for 24 plants. Five irradiated terminals and 25 irradiated laterals showed no significant growth. In the sixth week 14 normal terminals

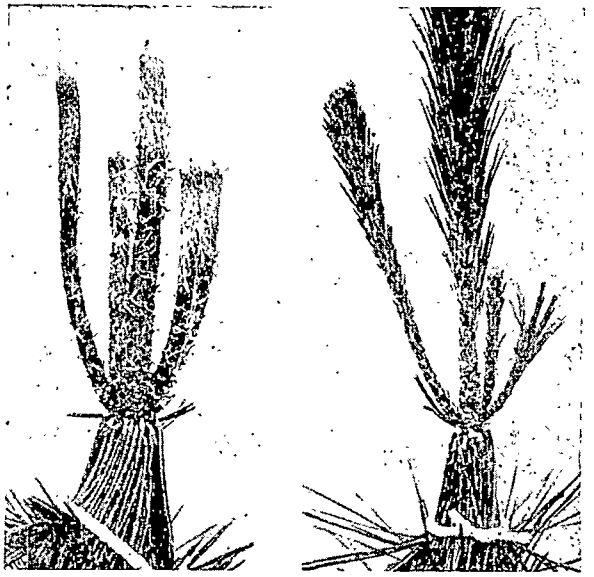

Fig. 1. (Left) Dormant terminal and lateral candles. (Right) Normal appearance of the candles after several weeks of growth. (Needles have been tied back to provide an unobstructed view)

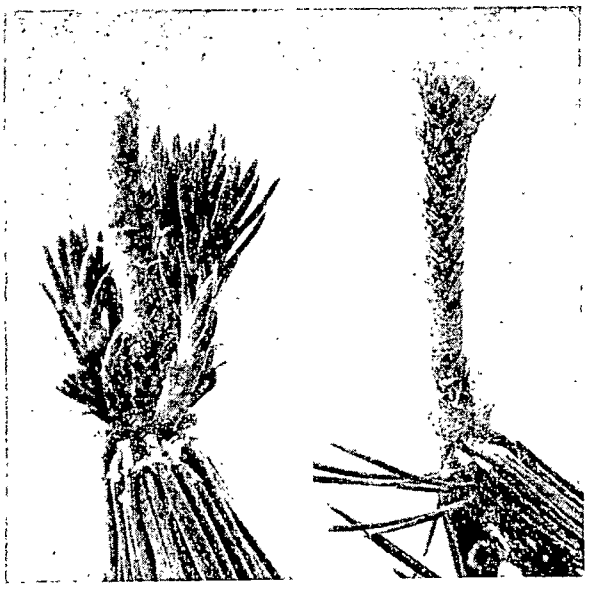

Fig. 2. (Left) Appearance of new buds arising at the base of an irradiated candle. (Right) Appearance of new buds arising at the tip of an irradiated candle. (Needles have been tied back to provide an unobstructed view)

showed a growth of 13·6 ± 5·6 cm; 20 laterals a growth of 6·4 ± 3·5 cm. In the irradiated trees 11 terminals showed a growth of 0·5 ± 0·4 cm, and 30 laterals a growth of 0·5 ± 0·5 cm.

Six of the trees displayed rudimentary male strobili (pollen cones) at the time of irradiation. Three of these trees were placed in the control group and the remaining three in the group to be irradiated. The strobili in both groups began development in the first week following irradiation. In the second and third weeks the strobili reached maturity and those of the control plants released copious amounts of pollen. However, the strobili of the irradiated plants, while reaching the same state of elongation, failed to show any release of pollen whatsoever. This phenomenon is similar to that reported by Mergen and Johansen[3] following chronic γ-irradiation of *Pinus rigida* at dose-rates of greater than 82 r./day.

Female strobili, or seed cones, developed in the control trees in six cases, while in no case did a similar development occur in irradiated trees. This latter phenomenon, however, may have been the result of chance selection rather than irradiation, since the rudimentary female strobili were not readily apparent at the time of irradiation and no attempt was made to ensure equal representation in both groups.

Late in the sixth week following irradiation, adventitious buds began to develop in the region immediately below the candles of the irradiated plants. By the tenth week 36 of the irradiated plants showed this type of development. Fig. 2 (left) shows the appearance of these buds at ten weeks. Brandenburg *et al.*[2] has reported a similar development from basal buds in the pinion pine. In addition to such development from obvious pre-existing basal buds, other buds appeared to develop *de novo* from the stem. Buds also were seen to develop from within needle groups, as commonly occurs when all meristematic tissue is removed from a normal pine. In three cases new buds developed along the length of irradiated candle, even though the particular candle itself failed to show any significant elongation.

In the ninth week following irradiation, at which time most of the shoots of the control plants had reached full growth and new buds were forming at their tips, it was noted that several of the irradiated candles were also in the process of bud formation at the tips, though they had failed to otherwise significantly elongate. Fig. 2 (right) shows the appearance of these buds at nine weeks. By the tenth week 22 irradiated plants exhibited this type of development and only 6 plants had failed to show any type of new growth. Similar bud formation at the tips of irradiated candles has not heretofore been reported in comparable dose ranges.

Such development of buds is of particular significance in that it has not been reported to occur under conditions of chronic radiation. Furthermore, it indicates an ability of the plants to survive and recover even after significant doses of acute γ-radiation. It would therefore be of interest to learn whether or not other species of pine might show a similar response or recovery under similar conditions.

This work was supported by contract *AT*(04-1) *GEN* 12 between the Atomic Energy Commission and the University of California, and by U.S. Public Health Services training grant *5TI-GM-796*.

BIOLOGY

Organization within the Central and Centrifugal Fibre Pathways in the Avian Visual System

Previous experimental studies[1,2] have established the existence of centrifugal fibres in the avian visual pathway and have shown that these fibres arise in the prominent isthmo-optic nucleus in the midbrain, that for a considerable part of their course they run independently of the optic nerve fibres, cross completely at the optic chiasma and terminate principally around the amacrine cells on the inner aspect of the bipolar cell layer as described in normal material[3,4]. The only known source of afferent fibres to the nucleus of origin of these fibres is the optic tectum[5], and there is evidence for some degree of organization within the projection of the tectum on the isthmo-optic nucleus[2]. This observation, when taken together with the electrophysiological evidence for the representation of the retina on the tectum[6], suggested, first, that there may be an ordered representation of the retina on the isthmo-optic nucleus, and secondly, that the nucleus may project in a similarly organized manner on the retina. This would mean that each part of the retina is reciprocally connected (through the tectum) with that part of the isthmo-optic nucleus from which it receives its centrifugal afferents.

This suggestion has been experimentally tested in three stages. In the first, the retinal projection on the tectum has been re-examined using the Nauta technique[7] following small, localized lesions in each quadrant of the retina. The results of this study confirm the pattern of retinal representation on the tectum as defined by Hamdi and Whitteridge[6]: the upper retinal quadrants project to the ventral half of the tectum, and the anterior (nasal) quadrants are related to the posterior half of the tectum. In the second series of experiments the details of the projection of the tectum on the isthmo-optic nucleus have been determined using the same technique after

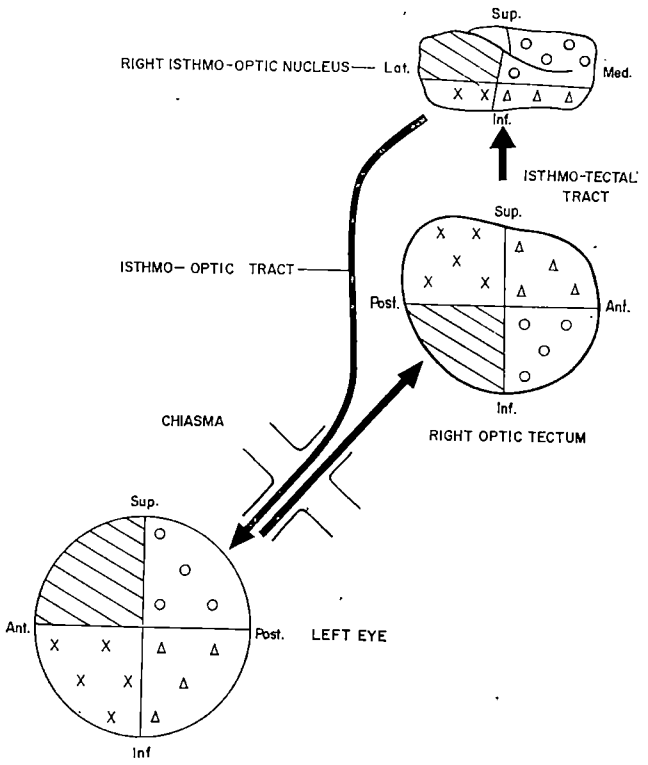

Fig. 1. Organization in the central fibre pathway in the relationship between the retina, optic tectum and isthmo-optic nucleus, and the reciprocal arrangement in the centrifugal projection from the isthmo-optic nucleus to the retina

small lesions of the tectum. The pattern of this projection is such that the dorsal half of the tectum is related to the ventral half of the isthmo-optic nucleus and the anterior half of the tectum to the medial half of the nucleus; that is to say, the retina is secondarily represented on the isthmo-optic nucleus in such a way that the superior retinal quadrants are represented in the superior half of the nucleus and the anterior quadrants in the lateral half of the nucleus. For the third stage in the analysis, it was necessary to determine the projection of the isthmo-optic nucleus on the retina with the retrograde cell degeneration method after lesions of varying size in the different retinal quadrants. The results have shown that there is again a definite organization in the projection of the centrifugal fibres to the retina, at least at the quadrantic level; thus the dorsal half of the nucleus sends its fibres to the superior half of the retina of the contralateral eye, and the lateral half of the nucleus to the anterior retinal quadrants (Fig. 1). It has not been possible to determine the relation of the isthmo-optic nucleus to the retina in greater detail, as small lesions of the retina do not result in detectable cellular degeneration in the nucleus—possibly because of collateral branching of the centrifugal fibres both in the brain and retina. Whether or not each centrifugal neurone influences only those ganglion cells from which it has indirectly received its afferent activation remains to be determined.

Use of Long Cavities for Aqueous Biological Tissue Samples in an Electron Spin Resonance Spectrometer

A recent communication from this laboratory[1] appears in some ways to have been misunderstood. We did not claim that the machine described was more sensitive than that of other workers, but described a system which we felt was of practical value for the examination of aqueous biological tissues and which, as stated in the communication, was a modified version of one used by Commoner and Townsend.

It has been shown by Stoodley[2,3] that, for a multimode rectangular H_{01n} cavity, when $n = 10$ the optimum thickness of sample to be used is 0·5 mm and that, under these conditions, the product of filling factor (ξ) and Q is $\xi Q \doteqdot 14{\cdot}0$. For a thicker sample of 1 mm in this mode $\xi Q = 7{\cdot}9$ so that, because ξQ is inversely proportional to the minimum concentration of radicals detectable and is a measure of sensitivity, there is a drop in sensitivity of about 2. For a 1-mm sample thickness in a cavity with $n = 2$, ξQ is 8·7, and experiments in this laboratory have confirmed that there is a gain in sensitivity of approximately 10 per cent at $n = 2$, compared with $n = 10$ for 1-mm samples. For the cavity with $n = 2$, at the optimum sample thickness (0·38 mm), ξQ is 35 and, consequently, Stoodley has shown that the sensitivity of our cavity and associated sample cell is some 4·4 times worse than it would be if a short cavity and a thinner sample were used. However, he also recognizes that "biological investigations are hampered by the necessity of using thin samples". We consider that the multimode cavity which enables an increased thickness and volume of sample to be used amply repays in ease and convenience the loss of 4·4 in sensitivity.

In a recently published paper Stoodley[3] gives a graph relating ξQ to sample thickness for $n = 2$ which, as stated above, has a peak value of 35 at sample thickness 0·38 mm. It is immediately apparent that the corresponding curve for $n = 10$ will represent a more slowly varying function since it will only rise to a peak value of 14, as already stated here. As a result, there will be much less dependence of sensitivity on sample thickness and also, it may be inferred, on the exact positioning of the sample at the node of electric field. In fact, the expression for the dependence of ξQ on sample thickness ($2t$) may be written as $\xi Q \propto \frac{t}{n + C_1 t^3}$, where C_1 is a constant, and that on displacement (b) of the centre of the sample from the node as $\xi Q \propto \frac{t}{n + C_2 K^2 t}$ where $K^2 = t^2 + 3b^2$. Substituting numerical values shows that a sample displacement of 0·5 mm in the long cavity ($n = 10$) gives rise to only one-third of the sensitivity change which would occur in the short cavity ($n = 2$).

In the case of those biological measurements where many samples have to be measured as quickly as possible, this represents a very valuable gain in ease of sample placement and measurement. In addition, the use of the thicker sample holder with animal or human tissues enables slices of tissue to be inserted much more easily and quickly than in a thin sample holder and, furthermore, makes it more possible to completely fill the sample holder with tissue in the time available.

Wilmshurst[4] also made several comments on the original paper[1], most of which were valuable but some were based on unjustified assumptions. First, Wilmshurst quotes Commoner[5] as claiming $2{\cdot}5–5 \times 10^{-7}$ M of Mn^{++} as the minimum detectable concentration, and he compared it with the one quoted from this laboratory of 3×10^{-6} M. However, Commoner's sensitivity[5] is based on a signal-to-noise ratio of 1 : 2 whereas our figure is based on a more realistic ratio of 2 : 1. Taking into account this factor of 4, Commoner's sensitivity[5] becomes 1 to 2×10^{-6}, not a

great deal different from our original one. Naturally, since Commoner uses a long cavity technique, of which Townsend was the originator, the factor of 4·4 resulting from the cavity length (slightly modified for the extra length which they use) will also apply to their machine.

Secondly, Wilmshurst assumes that we use a 723*A/B* Klystron giving 20 mW, and compares it with that used in a Varian machine giving 180 mW; as a result he suggests that we are a factor of 3 down in sensitivity compared with the Varian machine arising from the loss of power. This is not the case, since the Klystron which we used is a *KS*20*A* which gives a nominal 35 mW, so that we were only 2·3 down from this point of view. Since the sensitivity is 30 times worse than that of the Varian machine according to Wilmshurst, then this leaves a factor of 13·3 arising from the cavity and preamplifier circuit. Of this, the factor 4·4 arises from the cavity design, leaving a factor of 3 due to the circuit of the preamplifier; this agrees almost exactly with his measured noise figure (7 dB) of the preamplifier rather than with the factor of 4 dB which he calculated.

Finally, Wilmshurst made suggestions to improve the above noise figure and these circuit modifications have proved to be successful; we have used an *E*180*F* in preference to the *EF*89 which he suggested, however, because it has an equivalent noise resistance of only 460Ω which gives a marginal improvement.

Two further improvements have been made to the cavity: first, the tuning paddle method of matching has been discarded in favour of matching screws above the coupling iris to the cavity, and secondly, the modulation coils are now wound with two turns of 18 standard wire gauge bare copper wire instead of enamel-covered wire. This was because a large signal was found to arise from the enamel insulation at about $g = 2$, which was 5–10 gauss wide and which had not been present before and probably arose from low temperature charring of the enamel. Such a signal has also been observed by Assenheim[6].

All these improvements have lowered the minimum detectable concentration to about 10^{-6} M at a signal–noise ratio of 2 : 1.

In conclusion, we support the point of view put forward by Pake[7], who said that it was "advisable to view pontifications on the subject (signal-to-noise)—with vigorous independence of mind"!

Immunological Response to Implanted Adult Dwarf Tapeworms

Earlier immunofluorescent, radioisotopic, and diffusion chamber isolation investigations[1,2] indicated that antibodies, derived as a result of ova-induced *Hymenolepis nana* infestations, combined *in vivo* with adult tapeworms. The authors did not, however, presume that responsible helminth antigens were, necessarily, stage-specific. The work recorded here was carried out to determine whether or not adult cestodes are capable of immunological insult *in situ*. Implantation of adult parasites into the ileum of the mouse host, for various periods of time, was therefore considered. Under these conditions the cysticercoid stage, with tissue phase involvement, could be precluded or controlled without utilization of an intermediate host. This appeared to permit a singular investigation of the lumen stage of the parasitæmia, from the point of view of possible elicitation of a local and/or systemic immunological response.

Initially viable adult specimens of *Hymenolepis nana* were allowed to react *in vitro* against positive antisera in Wilson double-diffusion plates at 37·5° C. The mature tapeworms were maintained in 'CulturStat 199' (Baltimore Biological Laboratory, Baltimore, Maryland) containing Earle's base basal medium, penicillin and streptomycin, following transfers through several rinses of sterile phosphate buffered saline of *p*H 7·2. The 'Plexiglass'-constructed plates were previously subjected to ultraviolet light, and merthiolate was not added to the 0·75 per cent Bacto certified agar used. Rabbit antisera, produced against sonicated worm extracts (intramuscular injection with aluminium hydroxide gel), and antisera from mice, following a 3-week period of infection, were utilized as antibody reactants. In either case two precipitation bands were evidenced within 24 h. With a period of prolonged incubation as many as four bands developed when rabbit antiserum was reacted with secretions and/or excretions from viable hymenolepids as compared with numerous precipitin arcs formed when the same antiserum was reacted on agar slides against electrophoresed sonicated worm extract (Fig. 1).

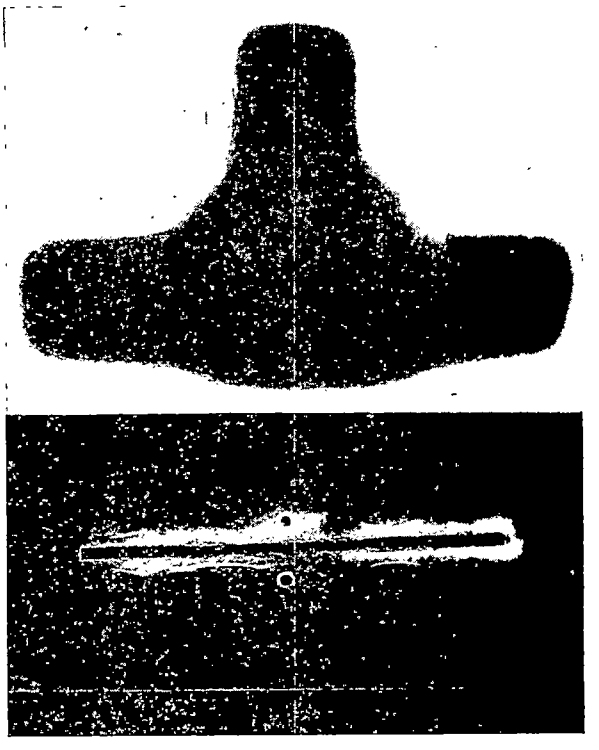

Fig. 1

The implantation procedure[3] was used, following the *in vitro* demonstration of the specificity of hymenolepid secretions and/or excretions, to ascertain whether or not such materials were exoantigenic during the lumen phase of the parasitæmia. Adult worms, obtained from infected *CBA/J* female mice, were transferred through several rinses of sterile phosphate buffered saline of *p*H 7·2, whereon they were implanted into the ileum of non-infected female mice weighing about 23 g. The surgical procedure was performed under 'Nembutal' anæsthesia and aseptic conditions. Following periods of

1, 2, 3, 4, 8 and 12 days, host mice were bled by cardiac puncture, killed and autopsied. Serum antibody was detected and titred by the indirect hæmagglutination method[4]. Formalinized sheep cells (Difco Laboratories, Detroit, Michigan) were tanned and sensitized with hymenolepid antigens. The sensitizing antigens were prepared by sonicating worms at 0° C for 3 min in phosphate buffered saline at 3 amp, followed by centrifugation at 4,340*g* for 30 min at 2° C. The nitrogen value for the supernatant was determined by micro-Kjeldahl analysis according to the Markham modification, adjusted to a value of 650 μg/ml. of antigen and used immediately to sensitize 1 ml. of a 2·5 per cent concentration of tanned cells.

Table 1. Detection of Serum Antibody versus Ileac-implanted *Hymenolepis nana* by Indirect Hæmagglutination

Groups	1	2	3	4	5	6
No. of animals per group	8	8	8	14	17	14
Periods of implantation	1	2	3	4	8	12
Average No. of worms implanted	9·6	8·3	8·5	7·4	7·4	7·0
Average No. of worms recovered	9·3	7·3	7·0	6·5	6·7	4·1
No. of mice in which all implants recovered and have hæmagglutination titres = or > 1 : 96	6	5	4	6	11	5
	+	+	+	+	+	+
Control groups*	*A*	*B*	*C*	*D*	*E*	
No. of animals per group	24	8	24			
Hæmagglutination	1 : 1536	1 : 1536	—	—	—	—

* *A*, Serum (not pooled) from mice infected for a period of 21 days with 5,000 ova; *B*, Serum (not pooled) from mice immunized with sonic worm extract (0·2 mg N) for a period of four days; *C*, Serum from normal mice; *D*, Antigen deficient reaction mixture; *E*, Test serum deficient reaction mixture.

Results (Table 1) indicate that antibody is engendered against adult dwarf tapeworms following implantation in the ileum of the host. The sensitivity of the indirect hæmagglutination procedure permitted detection of a systemic response as early as 24 h after implantation of only 8 worms. It appears, therefore, that hymenolepid exoantigens are capable of villus mediation and elicitation of a generalized immune response. The possibility of a local response is under investigation. Results of the advent of fæcal antibody will be presented following examination of the effect of irradiation of: (1) the ileum; (2) the mouse, exclusive of the ileum, on host response to implanted cestodes.

Choanocytes in the Skin of *Harrimania kupfferi* (Enteropneusta)

During an investigation of mucous secretion on the proboscis of *Harrimania kupfferi*[1] ultra-thin sections were made of the epithelium of various parts of the body including proboscis, collar and the anterior parts of the trunk. In the epithelium of the ventral part of the trunk, immediately behind the collar, a distinct choanocyte type of cell was encountered.

Fig. 1 demonstrates the flagellum and the collar in cross-section, that is, a section parallel to the surface of the epidermis. The flagellum in the centre of the ring of microvilli is seen to possess the usual pattern of nine peripheral double filaments and two central single filaments. The collar consists of a ring of microvilli. Each microvillus measures about 500 Å across, and the microvilli are set about 500 Å apart, at least in the basal parts of the complex. Some sections suggest that the collar may be funnel-shaped, the diameter of the collar increasing from the base. Between the microvilli is seen an amorphous or possibly fibrous material, probably mucus. It adheres closely to the surface of the microvilli, and in some cases it is extended between opposed sides of adjacent microvilli (Fig. 2).

It is readily seen that the structure described is morphologically identical with the collar and flagellum of Choanoflagellates[2] and of the choanocytes of fresh-water sponges[3,4].

Some of the sections seem to indicate that some of the material adhering to the microvilli has bent inward. This observation may suggest that by the activity of the flagellum water is drawn into the lumen of the collar through the intervillar spaces. Thus the structure may be functioning in a way similar to that found in the choanocytes of sponges[4].

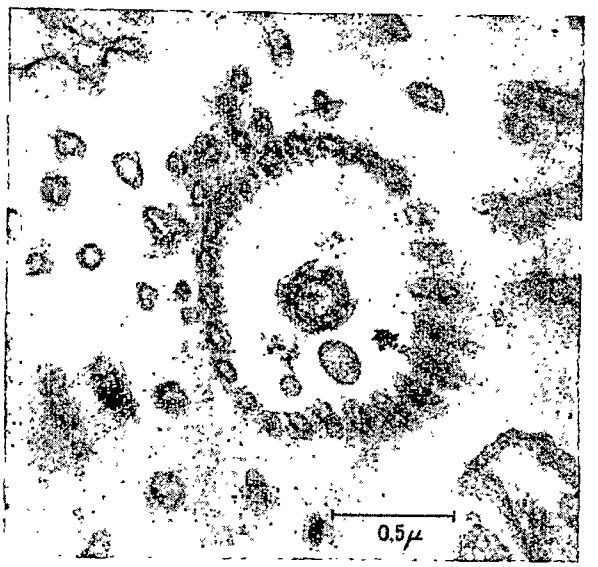

Fig. 1. Electron micrograph of collar and flagellum of the choanocyte in cross-section parallel to the surface of the epithelium. Outside the collar other microvilli are seen. Inside the collar are seen the flagellum, a couple of digitations of the cell surface and a speck of dirt

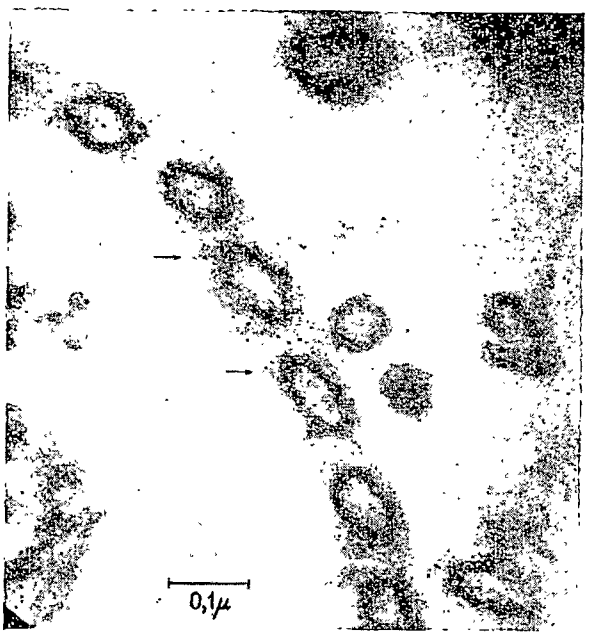

Fig. 2. The microvilli of the collar at a greater magnification. The unit membranes are clearly visible, and so is the amorphous material adhering to the surface of the microvilli. At arrows this material is bent inward (see text)

Fig. 3. Oblique cross-section of the base of a collar and flagellum. *F*, Base of flagellum; *C*, collar (somewhat distorted). The cytoplasm of the choanocyte is indistinguishable from that of the neighbouring cells, *A*, *B* and *D*

It might be suggested that the collar and flagellum belong to some sessile Choanoflagellate, embedded in the epithelium. Although only the outer parts of the choanocytes have been investigated with the electron microscope they evidently are very similar to the ciliated cells surrounding them, containing the same cytoplasmic structures and showing none of the features commonly found in flagellates (Fig. 3).

As will be described elsewhere[1], the other epidermal cells are also provided with a varying number of microvilli. This applies both to ciliated and mucous cells. In the ciliated cells the microvilli are evenly distributed between the cilia, while in the mucous cells the microvilli are often set as a brim along the border of the free cell surface. This brim shows a certain similarity to that of the choanocytes, but the row of microvilli is irregular and the flagellum is lacking. Obviously the function of the microvilli along the border of the surface of mucous cells is to lead the merocrine secretion free of the surface of the epithelium, which seems to be rather uneven, some cells protruding a few microns over the surrounding cells.

Of course, the appearance of choanocytes in Enteropneusta does not imply a close relationship between Parazoa and Stomochordata. It simply means that choanocytes are a more widespread structural feature than formerly believed, and not restricted to sponges and Choanoflagellates. The choanocytes can therefore no longer be used to support a close specific phylogenetical relationship between these two groups.

Syncephalastrum associated with Bovine Mycotic Abortion

INVESTIGATIONS into an unusually high abortion rate among dairy cattle in Hong Kong have shown that a number of abortions were associated with fungal infections. In one such infection, the fungus has been shown to be *Syncephalastrum racemosum* (Cohn) Schroet. This is an addition to the list of fungi which have been implicated in bovine mycotic abortion, and also increases further the number of phycomycete fungi known to be abortifacients[1,2].

The fœtus, aged 3 months, was examined and cultured within a few hours of abortion. After surface-sterilization of the entire fœtus in alcohol, amniotic fluid was extracted aseptically and streaked on to plates of 'Sabouraud Dextrose Agar' (Oxoid) supplemented with streptomycin at 40 units per ml. Small fragments of cotyledons, fœtal membranes and the embryonic heart, liver, lung and stomach were also surface-sterilized and plated on to the same medium. Plates were incubated at 25° C and at the local ambient temperature (about 30° C), and the cultures were examined after 2–7 days. After 2 days, plates containing amniotic fluid, fœtal membranes or cotyledons all yielded numerous colonies of *S. racemosum*, and the fungus also developed in lesser amounts from the cultured heart tissue. All other tissues remained sterile over the incubation period.

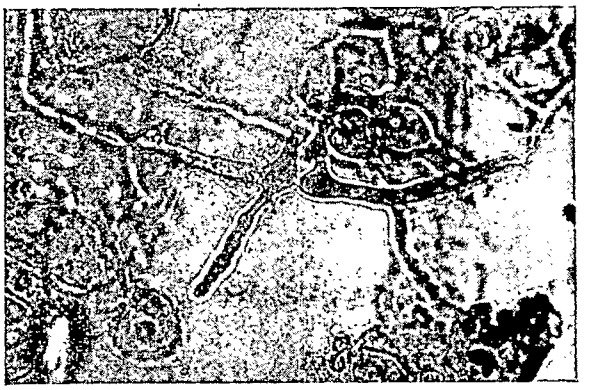

Fig. 1. Hyphæ of *Syncephalastrum racemosum* in the amniotic fluid of an aborted cow fœtus

The amniotic fluid contained small aggregations of mycelium, visible to the naked eye; they were found to be composed of broad, aseptate, hyaline hyphæ which branched and anastomosed (Fig. 1). Similar hyphæ were visible in crush preparations of cotyledonary and fœtal membrane tissue. No superficial development of fungus was seen on pieces of tissue maintained in high-humidity chambers for 3 days, and no lesions were seen on the other organs or on the skin of the embryo.

Syncephalastrum racemosum appears to have been isolated from animals only once previously[3], when it was considered to be an intestinal saprophyte of a pig. The origin of infection in the present instance is not known; *S. racemosum* is, however, ubiquitous in Hong Kong. I have found that spores of this fungus form a regular component of the air spora over the island, and that during the period February–August 1963 they occurred in proportions equal to those of two other phycomycetous fungi associated with abortion, namely, *Mucor* and *Rhizopus*. *S. racemosum* has also been isolated from soil[4], and investigations continue into possible sources of high inoculum.

I thank Mr. Ho Mang Hang for the photograph.

Gametophytic Plants induced from Single Cells of Moss Callus

Callus and callus-like tissues have been reported in a wide variety of plants. Steward *et al.*[1] have described induced organization of intact plants from 'aggregates' which accumulated from single cells of carrot callus; Bristow[2] has reported induction of discrete fern plants (sporophytic and gametophytic) from his callus cultures under influence of growth substances, and Bauer[3,4] has shown that varied sporophytic and gametophytic forms may be induced from callus of moss. This communication deals with aberrant moss plants, gametophytic in form, regularly induced from single-cell callus plantings of *Polytrichum commune* Hedw.

Diploid callus tissue of gametophytic origin (spore plantings) in this moss has been kept in culture with continuous proliferation through periodic transfers since its isolation[5]. No observable production of organized entities of either gametophytic or sporophytic character has occurred naturally in this period; the callus nature of the cellular aggregates has remained that of the original isolate when maintained on agar *in vitro* with media components favourable to growth of spores and normal moss gametophytes[6].

Recently, organized plants of aberrant form and structure, having limited features of normal gametophytes, have been regularly induced from this callus on media containing growth substances.

Single, isolated cells of the callus (Fig. 1*D*), separated from the callus aggregates by agitation in sterile water, were planted to ensure exclusion of normal protonemata cells which might have accompanied the callus in the original transfers. The basic difference in size and initial division patterns of the callus cells and normal germinating spores in this species is shown in Fig. 1, *A–E*. Substrate for the single cells was media used for routine moss culture with additions of 1 p.p.m. naphthaleneacetic acid (NAA) and 0·25 per cent sucrose. Culture chambers were small Petri dishes sealed with polyethylene film. Glass micropipettes were used to transfer the single cells.

Isolated cells thus planted normally begin divisions within about four days (Fig. 1, *D*, *E*), and the accumulation of an irregular cellular mass rapidly follows. Organized meristematic areas, portending the induced plants, appear at the periphery of the callus aggregate in about two or three weeks. Sections of the small cellular masses show an inner orientation and organization of cells long before emergence of the differentiated plants (Fig. 1*G*). Regularly 100 per cent of the cultures in a series of trials are successful, and numerous plants are commonly induced from the aggregate of a single cell culture.

The new gametophytic-appearing entities have definite organization, large, multicellular apical meristems and predictable patterns of division and differentiation, and they often bear rudimentary leaf-like appendages (Fig. 1*F*). The initial growth is rapid, distinctly exceeding that of the callus aggregate on which they originated. Later (within 3–7 weeks) growth lessens in the absence of isolation and sub-culture, and the callus accumulations may gradually encompass the organized plants. The apical meristematic region of the plants under such conditions ordinarily begins to form callus.

Plants isolated and sub-cultured on media of the type which supported their initiation continue to grow, and limited branching is common (Fig. 1*F*). Growth substance is clearly essential to both formation and maintenance of the organized plants, as also noted by Bristow in similar trials with fern callus[2].

An obvious maturity and subsequent senility are evident in the transplants, whether transferred often or not. This manifestation occurs generally within three months after the original planting under growth conditions maintained for normal moss.

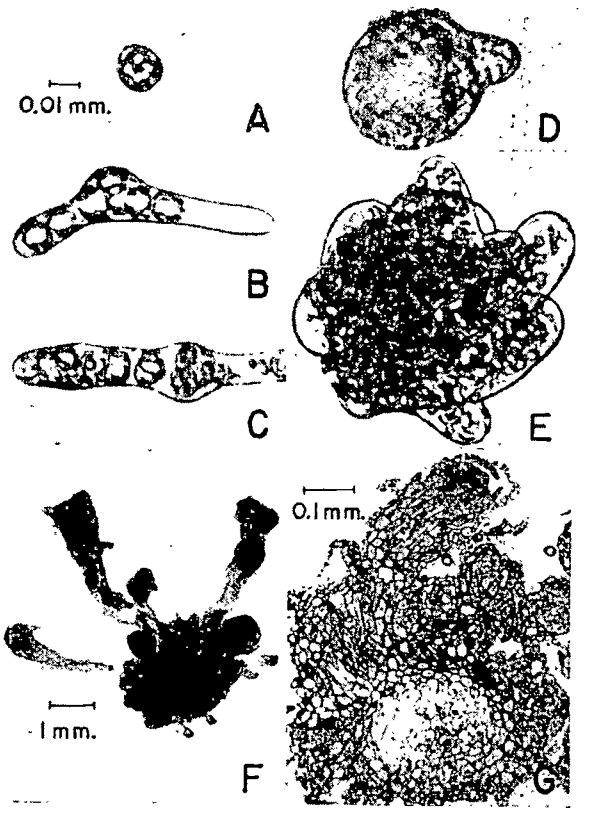

Fig. 1. *A*, *B*, *C*, ungerminated and germinating spores of *Polytrichum commune*, showing patterns of cell division and common orientation of growth in two directions. *D*, *E*, single callus cell, undergoing first division, and several-celled callus aggregate resulting from typically random divisions (scale in *A* is applicable to *A–E*). *F*, organized plants arising from callus aggregate within six weeks after callus was planted on medium containing 1 p.p.m. NAA. Leaf-like appendages are at tip; branches occur at sides. *G*, section of callus aggregate showing internal organization and (at top) detail of young meristematic tip of induced plant

Limited induction of these organized plant entities also results from use of other concentrations of NAA (0·1–10 p.p.m.); 0·1–10 p.p.m. of indole-3-acetic acid; and 2,4-dichlorophenoxyacetic acid in concentrations of 1–100 p.p.m. Gibberellic acid and indolebutyric acid have induced no responses.

The induced plants show essentially no sporophytic characteristics, as found in other mosses by Bauer[3] or by Lal[7] in certain other species, even though the callus in our experiments is determined to be diploid. The general aspect is that of a gametophyte, yet each new plant has a massive meristem and scale-like leaves (or none).

These aberrant plants are uniformly predictable; they can be induced with perfect regularity on appropriate media, and they arise either from single cell plantings on the initiating medium or from small aggregates of callus grown on the appropriate substrate. No special techniques are required to isolate the cells or to promote their subsequent growth.

This work was supported by grant *G*–19369 from the U.S. National Science Foundation. I thank Barbara Moore, Alvin Engelke and Sue Ellen Frederick for their assistance.

Site of Action of Copper in Photosynthesis

Early observations on the presence of copper in chloroplasts[1] and the inhibition of photosynthesis by several reagents which are regarded as specific copper antagonists[2] established the concept that this element is perhaps a functional component of the photosynthetic system. Recent findings on the presence of a cytochrome photo-oxidase in chloroplasts[3] and the subsequent isolation of a copper–protein (plastocyanin) with characteristics identical to those of cytochrome photo-oxidase[4] provide additional support for a specific role of copper in photosynthesis.

Published experiments of Arnon[5] and Trebst and Eck[6] demonstrated that both photosynthesis and the Hill reaction are sensitive to copper-chelating agents. In addition, Spencer and Possingham[7] showed that chloroplasts from copper-deficient plants had a decreased Hill reaction activity. These findings have been interpreted as indicating a requirement for this nutrient in at least one of the partial reactions in the overall mechanism for oxygen evolution. In contrast to these data, Kok *et al.*[8] reported that the apparent quantum yield of the photo-oxidation of cytochrome, as catalysed by the photo-oxidase system, is increased by wave-lengths above 690 mμ. They concluded that only photochemical system 1 (ref. 9) is functional in this reaction. The present-day interpretation of this finding is that the plastocyanin does not function directly in oxygen evolution but rather in reactions leading to the generation of a strong photoreductant.

Whether or not a certain effect on photosynthesis is restricted to the mechanism of oxygen evolution or reactions culminating in the reduction of carbon dioxide can be tested by examining the capacity for photosynthesis, photoreduction and the quinone–Hill reaction in normal and treated algal cells. In several green algae, containing an adaptable hydrogenase, the photochemistry and carbon dioxide fixation may continue even though oxygen evolution has been eliminated. Consequently, certain specific poisons and manganese deficiencies inhibit the Hill reaction but do not influence photoreduction. On the other hand, cyanide and phosphorylation uncouplers (dinitrophenol, *m*-chloro carbonyl cyanide phenylhydrazone), for example, inhibit both photosynthesis and photoreduction without strongly influencing the quinone–Hill reaction of algae. The usefulness of this technique is apparent when the success of localizing the effects of *o*-phenanthroline[10], manganese deficiency[11] and DCMU[12] on photosynthesis is considered.

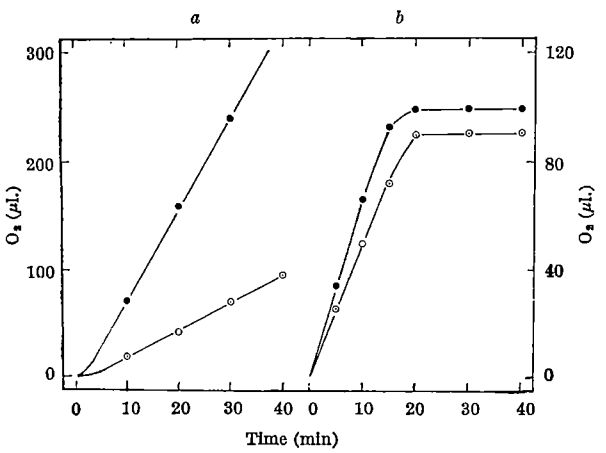

Fig. 1. *a*, Photosynthesis of normal (○) and copper-deficient (●) *Scenedesmus*. Manometric readings (corrected for dark respiration) are for oxygen formation. Experimental conditions: normal cells grown autotrophically with 1 × 10^{-6} M $CuCl_2$ present in culture medium. Copper deficient cells maintained through three transfers and used when six days old in the last transfer. Temperature = 25° C. Buffer = Warburg's No. 9 carbonate–bicarbonate. Gas phase = air. Light intensity = 18 k lux. Chlorophyll concentration = 0·25 mg/vessel. *b*, Quinone–Hill reaction of normal and copper deficient *Scenedesmus*. Reaction conditions were the same as described above except for the following: Buffer = 0·05 M phosphate, *p*H = 6·5. Gas phase = air – 4 per cent CO_2. Quinone concentration = 1 mg/3 ml.

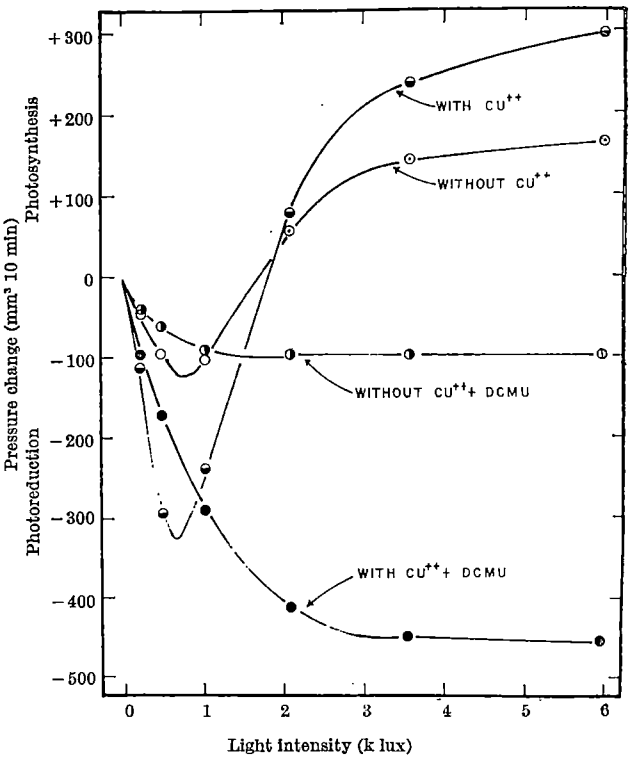

Fig. 2. Rate of photoreduction of normal and copper-deficient *Scenedesmus* at various light intensities with and without DCMU (2 × 10^{-6} M). Reaction conditions same as outlined in legend for Fig. 1*a* except for the following: Buffer = 0·05 M phosphate, *p*H = 6·5. Gas phase = hydrogen – 4 per cent CO_2. ◒, = control; ●, control + DCMU; ○, = copper-deficient; ◑, deficient + DCMU

Cells of *Scenedesmus obliquus* strain D_3 were grown in a medium which had been extensively purified of heavy metals by co-precipitation with calcium phosphate followed by solvent extraction with dithizone dissolved in chloroform. Spectrographically pure solutions of manganese, zinc, molybdenum, cobalt and boron were used for supplying the minor elements required for growth. The capacity for photosynthesis and quinone–Hill reaction of cells grown with and without copper is shown in Fig. 1*a* and *b*. At saturating white light intensity, photosynthesis of deficient algae is reduced by about 65 per cent whereas the Hill reaction rate is only slightly inhibited (maximum of 25 per cent in four separate experiments).

When normal and deficient cells are adapted to an atmosphere of hydrogen–4 per cent carbon dioxide, a pattern of photoreduction is obtained as illustrated in Fig. 2. Cells grown with copper show a normal pattern for photoreduction. Photoreduction by deficient cells is, however, markedly altered. This inhibition becomes more apparent when photoreduction is stabilized with DCMU; in the presence of this herbicide photoreduction by copper deficient cells is inhibited by approximately 78 per cent. From Fig. 2 it is also apparent that the de-adaptation process, that is, the return to normal photosynthesis, is not influenced as would be expected if the capacity for oxygen formation had been altered by the deficiency.

In 1961, Bishop and Gaffron[13] observed that the low apparent quantum yield at 705 mμ for photosynthesis by *Scenedesmus* and *Anhistrodesmus* could be increased by forcing the cells to perform photoreduction. The conclusion drawn at that time was that photoreduction requires the energy derived principally from pigment system I. The parallelism between this finding, Kok's

observation on the quantum yield of cytochrome *c* oxidation, as catalysed by plastocyanin and *P*–700 (ref. 8), and the requirement for copper in photoreduction as indicated by the data presented here suggests that copper is an essential component of the electron transport mechanism of pigment system I.

I recognize that the reduced photosynthetic and photoreductive activity associated with the nutrient deficiency does not demonstrate conclusively the precise function of the element in question. Although the effects observed may be due to a secondary response of the nutrient's direct action, normal rates of photosynthesis and photoreduction are recovered within 24–36 h after addition of copper. This recovery precedes the restoration of the chlorosis which also accompanies copper deficiency.

A more detailed description of these results will be published later. This investigation was aided by the U.S. Atomic Energy Commission (contract *AT*. (45–1)–1783).

MICROBIOLOGY

Pigment Formation by *Acetobacter acetigenum* in a Lactate-buffered Glycerol Medium

Few observations have been recorded on pigmentation in *Acetobacter* species. Among them *A. melanogenum* forms a black pigment and *A. roseum* a red pigment[1]. Carr and Shimwell[2] have reported the production of dark brown, water-soluble pigment by *A. aceti*. This communication reports the formation of a wine-red pigment by *Acetobacter acetigenum* in a lactate-buffered glycerol medium.

The medium (referred to as Medium *C*) was made up as follows: to 1 l. distilled water was added 2·0 g potassium dihydrogen phosphate, 1·0 g crystalline magnesium sulphate, 0·01 g crystalline ferrous sulphate, 2·5 g ammonium hydrogen phosphate, 0·002 g calcium D-pantothenate, 0·002 g riboflavin, 0·0001 g biotin, 10·2 g lactic acid, and 30·0 glycerol. After dissolving the lactic acid and salts, the *p*H was adjusted to 4·6 with potassium hydroxide and the solution was sterilized at 10 lb./in.^{2} for 15 min. Finally, the vitamins were added in 2 ml. aqueous ethanol (50 per cent by volume). One l. of Medium *C* was dispensed in each of twenty-five 250-ml. conical flasks previously sterilized for 20 min at 15 lb./in.^{2}, and inoculated with an active culture of *A. acetigenum* N.C.I.B. 8132, a cellulose-forming micro-organism. Seven 'Pyrex' tubes, containing exactly 8 ml. of Medium *C* (uninoculated), served as controls. The inoculated conical flasks and the seven 'Pyrex' tubes were maintained at 30° C. At the end of 7, 10, 13, 14, 17 and 21 days, 8 ml. of the culture medium from the conical flasks were carefully released by a sterilized pipette and its optical density was measured against the contents of the 'Pyrex' tubes serving as controls. For this purpose a Hilger Spekker was used fitted with spectrum violet No. 606 Ilford colour filters.

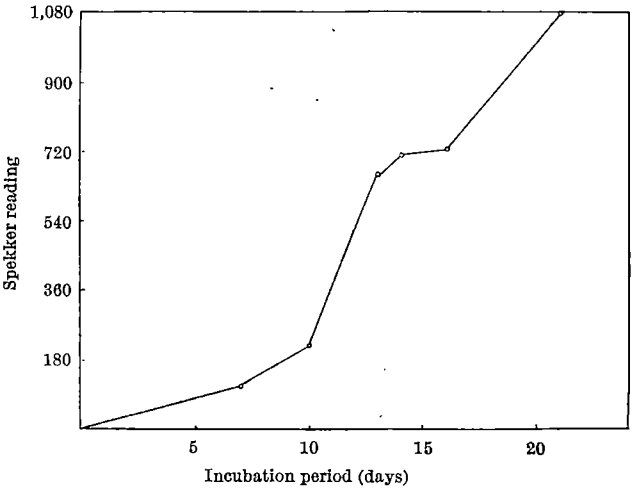

Fig. 1. Pigment formation during the growth of *Acetobacter acetigenum* in glycerol medium

The relationship between the number of days of incubation and accumulation of pigment is shown in Fig. 1; the elaboration of the colouring material seems to increase progressively.

In further experiments 1 l. of Medium *C* was prepared and dispensed aseptically into twenty-five 250-ml. conical flasks and inoculated with a growing culture of *A. acetigenum*. The cultures were maintained statically at 30° C for 21 days. The culture fluid was then pooled, Seitz-filtered and concentrated ten-fold, yielding a wine-red liquid. After preliminary trials with various solvents, isoamyl alcohol was found to be the most promising solvent for the extraction of the colouring matter.

In collateral investigations we have noticed a progressive loss of colour (greenish yellow) of Medium *C* (with ethylene glycol as the primary carbon source) during the dissimilation of ethylene glycol by *A. acetigenum*, ultimately becoming colourless after three weeks. It may be noted that the wine-red colour developed only in static cultures of *A. acetigenum* maintained on glycerol medium and not in the shaken cultures on glycerol. No attempt has been made at isolation, analysis and chemical characterization of the colouring matter, as our efforts were mainly directed towards the isolation of sugars[3] formed by the action of *A. acetigenum* on lactate-buffered glycerol medium, during the synthesis of cellulose. The pigment is presumably a manifestation of some metabolic by-product.

ENTOMOLOGY

Fossil Diptera and Continental Drift

It is well known that many plant and animal taxa have what has been termed an 'Antarctic' or 'Antarctogaean' distribution, that is, they are mainly or entirely restricted to southern Australia and/or New Zealand, southern South America, and, in some cases, South Africa. This

has been accepted by many biogeographers as evidence of an ancient connexion between these land-masses, probably via the Antarctic continent. In particular, it is seen as strong evidence in favour of Wegener's hypothesis of 'continental drift', a theory now attaining some respectability in the eyes of the geophysicists[1] who were formerly its principal opponents.

Opposition from biogeographers[2,3] has usually taken the form of deriving present 'Antarctic' distributions from earlier Holarctic distributions, the taxa in question being considered terminal isolates of groups which have suffered extinction in northern lands. In opposition to such views, it seems relevant to quote here some comparisons between the Recent dipterous fauna and that known from Tertiary fossils of the Northern Hemisphere.

In a survey of the known Tertiary fauna, one is immediately struck by the absence of genera at present recognized as 'Antarctic'. A good example is furnished by the family of fungus-gnats (Mycetophilidae), of which fossils, principally Oligocene, are reasonably abundant. By my own count, 120 genera are currently recognized in the Recent fauna and, of these, 35 are known from the Tertiary[4,5]. There are at least 11 genera with 'Antarctic' distributions: *Australosymmerus*, *Nervijuncta*, *Paramacrocera*, *Allocotocera*, *Aneura*, *Parvicellula*, *Stenophragma*, *Neoaphelomera*, *Paratrizygia*, *Austrosynapha*, and *Paraleia*; none of these is known from the Tertiary fauna. A simple χ^2 test for independence applied to these figures gives $\chi^2 = 4{\cdot}99$, $P < 0{\cdot}05$. It seems likely that other examples of 'Antarctic' genera will be revealed by further examination of southern faunas; also, the total number of genera under consideration could be reduced by eliminating specialized, endemic forms. Such corrections would reduce still further the likelihood that the observed absence of 'Antarctic' genera from the Tertiary fauna is due to chance alone. It is suggested therefore that their apparent absence represents a historical fact; and that, in accordance with Wegener's theory, they evolved in isolation, during the Mesozoic, on a southern supercontinent.

GENETICS

Sub-line Differences among C57 Black Mice in Response to Trypan Blue and Outcross

THERE exist many sub-lines of the highly inbred *C57* Black strain of mice. One of the characteristics of the *C57* Blacks, especially noted in sub-lines six and ten, has been the occurrence of sporadic eye defects[1–3], attributed to non-hereditary variability in a genetically determined threshold for abnormality[1]. The anophthalmic phenotype of the mouse has been extensively examined by Chase[1,4] and, more recently in the *ZRDCT–An* line, by Beck[3,5,6]. It is characterized by complete bilateral eyelessness among 90 per cent of the individuals homozygous for the recessive oligogene (*ey*) and most of the polygenic modifiers, and severe microphthalmia in the remaining 10 per cent.

Barber[7], using trypan blue as a teratogenic agent, reported the induction of unilateral eyelessness among fœtuses heterozygous for *ey*, and not among the homozygous normal control population. Gillman *et al.*[8] had discovered the teratogenicityof tr ypan blue, and Hamburgh[9] had shown that the dye was indeed teratogenic in mice. Beck[6], also using trypan blue, demonstrated a higher incidence of eye defects among fœtuses heterozygous for *ey* in crosses of *ZRDCT–N* × *ZRDCT–An* than among homozygous normal pure line *ZRDCT–N* treated in the same way. Additional novel features of Beck's experimental system were the bilateral nature of a number of the defects, and, regardless of whether one or both sides were affected, the eye reduction could be either complete or partial. Beck's findings, in which the principal difference between the two experimental groups of animals was the presence or absence of the mutant *ey* allele on one of the pair of chromosomes, when added to Barber's earlier findings, strongly suggest that *ey* is able, in single dose, to bring animals closer to a threshold for abnormality. If so, then this might be a useful method for detecting subtle differences between groups of animals.

This communication presents the results of an experiment in which the same treatment as has been described[6] was applied to two different sub-lines of the *C57* Black strain. Three intraperitoneal injections, each of 0·25 c.c. of a 0·3 per cent solution of trypan blue in 0·9 per cent sodium chloride, were administered during the seventh, eighth and ninth days of gestation to *C57BL/10 Ch* and *C57BL/6 Fs* females crossed with males of their own or *ZRDCT–An* lines. The treatment was designed to maximize the occurrence of eye defects and minimize

Table 1. ABNORMALITIES AT BIRTH AMONG UNTREATED LITTERS

Cross ♀	Cross ♂	No. of litters	No. of progeny Normal	No. of progeny Abnormal	Description of abnormalities	Frequency (% ± *S.E.*) of abnormalities
C57BL/10	*C57BL/10*	15	85	8	2+/m, m/+, m/m, m/an, s/an, 2s/m	8·6 ± 2·9
C57BL/6	*C57BL/6*	26	138	16	3+m/, 3+/s, 2m/m, 2m/s, 2s/m, 2s/s, s/an, an/s	10·4 ± 2·5

other abnormalities. Time of insemination was detected by the copulation plug method[10], and the day of insemination was considered day zero. Treated and untreated pregnant females were dissected on the 18th day of gestation. The number of dead and resorbed fœtuses was noted; living fœtuses were examined for eye defects and other gross morphological abnormalities. The results were analysed with respect to frequency and variety of defects and frequency of post-implantational prenatal mortality. Another and larger body of results was collected from untreated litters at birth. The tests of significance applied to the data were the χ-square test of homogeneity and the Student–Fisher grouped-method t-test for the comparison of small samples[11].

At birth (Table 1) there are spontaneously occurring defective individuals in all crosses. There are no significant differences between the pure lines or between the two F_1 samples. Each F_1 does, however, present fewer abnormalities than its corresponding pure line cross ($t = 3{\cdot}1$, $d.f. = 270$, $P < 0{\cdot}002$ for sub-line 10 crosses; $t = 2{\cdot}0$, $d.f. = 227$, $P < 0{\cdot}04$ for sub-line 6 crosses). The defects among the F_1 were, in each case, mild unilateral microphthalmia. A reciprocal outcross of untreated *ZRDCT–An* females mated with *C57BL/10* males, although not specifically a part of this experiment, did produce a group of eight litters containing a total of 61 individuals, all of which were normal.

An examination of untreated litters at 18 days of gestation (Table 2) reveals comparable frequencies of abnormalities to those found at birth. More cases of slight aberration are noted owing to the greater ease of detection by virtue of greater tissue transparency. Examination at this time also provides a measure of prenatal mortality and thus allows the additional criterion of response to the toxic properties of the dye to be assessed. Spontaneous prenatal mortality in all four crosses is about the same. The decreased frequency of eye defects in the *C57BL/10* × *ZRDCT–An* relative to pure line *C57BL/10* crosses is, as in the data at birth, significant ($t = 2{\cdot}5$, $d.f. = 73$, $P < 0{\cdot}02$); the results from the *C57BL/6* matings are not extensive enough to reveal differences, if they exist.

Among the treated litters (Table 3) there are no differences in response between the pure line matings, but the two F_1's do differ markedly from one another both with respect to the frequency of eye defects ($t = 3{\cdot}6$, $d.f. = 73$, $P < 0{\cdot}001$) and mortality ($t = 3{\cdot}8$, $d.f. = 108$, $P < 0{\cdot}001$). The *C57BL/6* × *ZRDCT–An* litters are highly susceptible to the teratogenic and toxic effects of the treatment; their response resembles that of the *ZRDCT–N* × *ZRDCT–An* reported elsewhere[6]. The *C57BL/10* × *ZRDCT–An*, on the other hand, are, of all four crosses, the most resistant to the treatment. They seem to show heterotic vigour.

These results indicate that, by the use of a teratogen coupled with appropriate crosses, one may demonstrate what are probably polygenic differences in two sub-lines of the same inbred strain, exerting modifying effects on the processes of eye development. In the absence of the double treatment (that is, outcross to anophthalmic mice and exposure to the teratogen) the two groups of animals are, with respect to the criteria of classification used, indistinguishable.

This work was supported in large part by U.S. Public Health Service fellowship 10,004 from the National Institute of Neurological Diseases and Blindness. The work was done at the Mammalian Genetics Center, Department of Zoology, University of Michigan, Ann Arbor.

Preservation of the Heterozygous Diploid Condition in Industrial Micro-organisms

The discovery of parasexuality in *Aspergillus nidulans*[1] has led to the possibility of breeding strains of asexual micro-organisms for increased yields of a desired product[2]. It has been reported that in *Penicillium chrysogenum* a synthesized heterozygous diploid gave a higher yield of penicillin than either haploid parent, perhaps through an effect of heterosis[2]. It might sometimes be desirable therefore to use a heterozygous diploid of *P. chrysogenum* or other micro-organism in an industrial fermentation. A heterozygous diploid, however, does not breed true, but can give rise to segregants as the result of mitotic crossing-over or non-disjunction of chromosomes[3]. The rate of segregation may vary in different organisms, and if it were high then the accumulation of segregants during the course of a fermentation could have an adverse effect on the yield of a product. To prevent this or to avoid the consequences there are two possibilities, namely, to reduce the rate of segregation, or to select against segregants as they are formed.

Chemical and physical agents are known which can increase the rate of segregation[4] and it has also been demonstrated that the effectiveness of some segregation inducers can be obviated by chemical treatments (for example, see ref. 5). So far as is known, however, such treatments do not affect the rate of natural segregation. The second method is therefore suggested as a means of preserving the purity of a heterozygous diploid culture as much as possible during the course of a fermentation.

In *P. chrysogenum*, when segregants are isolated from a heterozygous diploid made between strains which are not closely related, then these segregants tend to be of haploid parental type more often than of recombinant type[6,7]. This process has been termed parental genome segregation[7]. Successive mutagenic treatments of ancestral strains of the haploid parents, for the derivation of isolates of

increased penicillin yield, could have led to different chromosomal rearrangements in each haploid parent which restricted recombination at the diploid stage[6,7]. If, as immediate parents of such a diploid, genetically labelled strains were used which grew poorly in a production fermentation medium, then, because of parental genome segregation, selection would operate against the majority of segregants which arose. The haploid parent strains could be labelled with mutations imposing genetical restrictions on growth—so-called 'dwarf' mutations. A second class of mutants which could serve as parents would be auxotrophs which would grow poorly on complex media but normally on a minimal medium supplemented with their growth factor requirements. Such mutants have been found in *Aspergillus nidulans*[8] and *Neurospora crassa*[9], and presumably their restricted growth on complex media is due to the presence of inhibitory substances in such media. Although in *P. chrysogenum*, mutation to auxotrophy often leads to a reduction in penicillin yield[10], this is usually a pleiotropic effect of the auxotrophic locus, which is recessive[10,11]. Similarly it could be expected that recessive dwarf mutations might not affect penicillin titre in the heterozygous diploid stage if they were non-allelic. If a diploid were made between dwarfs or auxotrophs of the sort discussed, then in a complex production medium segregants of parental type would be contra-selected.

In micro-organisms in which heterozygous diploids have particular advantages over their haploid parents, and segregation occurred at an excessive rate, it may be possible to ensure parental genome segregation if it did not already exist. Heavy doses of X-rays lead to frequent chromosomal rearrangements[12]. The sequence of events would therefore be the induction of parental genome segregation by using X-rays as a mutagenic agent for genetically labelling both haploid parents and the subsequent isolation of dwarf mutants, or suitable auxotrophs, as discussed above, to synthesize the diploid. Multiple labelling by X-ray treatment could be considered as a method for increasing the possibilities of restricting recombination.

AGRICULTURE

Hydrocyanic Acid Content and Nitrogen-fixing Capacity of Guar

Cyanogenesis has been extensively investigated in many plants chiefly because of the effect that the hydrocyanic acid could have on livestock. Since hydrocyanic acid is very toxic to plants, it does not occur in the free form but combined with sugars to form an insoluble compound, known as cyanogenetic glycoside.

The six cyanogenetic glycosides that have been most investigated are amygdalin, lotusin, dhurrin, sambunigrin, linamarin and lotaustralin. Amygdalin is the best known of these and was first isolated in 1830 from bitter almond and related plants. On hydrolysis in the presence of an enzyme it yields glucose, benzaldehyde and hydrocyanic acid.

Quisimbine[1] listed more than 300 separate species of seed-bearing plants known to contain hydrocyanic acid; including 52 members of the Leguminosae, work in this field has been concentrated mainly on the different species of sorghum, Sudan grass, Johnson grass, white clover and arrow grass. Leeman[2] has given an extensive bibliography on hydrocyanic acid in grasses. Nothing has been found in the literature concerning the content of hydrocyanic acid in guar. The main aim of this communication is to report some of the findings in the preliminary work on guar.

Guar (*Cyamopsis tetragonoloba*) or cluster bean was introduced into Nigeria from India about 1962 and seems to have aroused some interest. It was hoped that it would become an acceptable protein supplement and replace the more expensive imported peas. Guar beans are recommended to be eaten at a young stage when they are soft and succulent. At this stage the taste closely resembles that of lima beans. Matured guar beans are tough, fibrous and less palatable.

In preliminary experiments the guar beans were planted in beds at 3-ft. intervals. The yields in the first crops were most encouraging. Hydrocyanic acid was determined in two categories, the young and the matured beans, using the $AgNO_3$ method[3]. The fresh beans were cut into pieces, distilled water was added and the material was macerated at room temperature for 2 h. Further distilled water was added and the macerate was steam-distilled into 20 ml. of 0·02 N $AgNO_3$ solution, acidified with 1 ml. HNO_3. After collecting 150 ml. the excess $AgNO_3$ was titrated with 0·02 N KCNS using ferric alum indicator.

The HCN content of the young beans ranged from 40 mg to 70 mg, with a mean value of 55 mg HCN per 100 g dry matter, while the matured beans contained only traces which could not be estimated by this method.

This observation is in accordance with the work of other investigators in this field. Swanson[4] found most hydrocyanic acid in Sudan grass when the plants were young and in a vigorous growth. Everist[5] claims that young shoots of Sudan grass and grain sorghum are more dangerous than old ones and that they are most dangerous when young side shoots are plentiful. Others have arrived at the same conclusion[6–9].

The best known cyanogenetic glycoside in Nigeria is linamarin. This is chiefly found in one of our staple foods, cassava (*Manihot utilissima*). Linamarin on hydrolysis yields glucose, acetone and hydrocyanic acid. Dean[10] gives figures of 4–36·5 mg/100 g fresh root for 14 varieties. Corneia[11] found 5–15 mg/100 g and showed that the peel, which is 17·06 per cent of the fresh root, contained 60 per cent of the total HCN and practically all of this was destroyed on boiling.

In Nigeria, cassava is made into 'gari' by finely grating the peeled root, which is then placed in a sack and fermented for about four days. The product is then fried at about 100° C and sieved. The average HCN content of such gari is about 1·5 mg/100 g (1–2 mg per cent). Hence by this process most of the HCN is eliminated. Most of the HCN content of guar beans could be eliminated by cooking. On the other hand, they could be dried before use. Paula and Rangel[12] reduced the HCN content of cassava as follows:

Fresh root	3·9 mg HCN/100 g
Sun-dried root	1·7 mg HCN/100 g
Oven-dried root	0·6 mg HCN/100 g
10 min boiling	0·0 mg HCN/100 g

However, since the bulk of the HCN would be removed in the preparation and it would be unlikely to constitute the principal item of diet, the toxic levels quoted (for example, 24·1 mg/100 g said to have caused two deaths) would not be approached.

However, there are other potential uses to which guar could be put; first, as a protein supplement for cows. In this connexion the conclusions arrived at by Boyd *et al.*[8], from the analysis of nearly 500 samples of Sudan grass, are relevant (Table 1).

Table 1

mg HCN/100 g dry tissue	Toxicity
0–25	Very low (safe pasture)
25–50	Low (safe pasture)
50–75	Medium (doubtful)
75–100	High (dangerous pasture)
>100	Very high (very dangerous pasture)

In comparison, HCN content of guar (55 mg/100 g) may therefore be regarded as being medium. However, guar could be quite safe in pasture if it were grazed at a mature stage, since the content of HCN is then negligible.

The 'apparent yield' of guar from the preliminary experiment exceeded that of any other native beans that have been planted on the University Farm. Analyses of guar beans and native cowpea seeds (*Vigna unguiculata* Walp) are given in Table 2 for comparison.

Table 2. Comparison of Percentage Constituents of Guar Beans and Native Cowpea

	Moisture	Ash	Protein	Crude fibre	Nitrogen-free extractives	Fat
Cowpea seeds	8·70	3·78	22·75	1·81	67·28	2·46
Guar beans	6·9	3·4	25·0	10·0	52·1	2·6

It is obvious from Table 2 that the protein content of guar beans exceeds that of cowpeas and hence guar beans could be used as a source of protein.

This legume might find widespread use as soil-improving (nitrogen-fixing) crop, an annual row crop, a cash crop (for human consumption), and home-grown protein feed for stock.

If the plant should prove satisfactory for all these purposes it would be superior to the legumes now used as fallow crops (cowpea, pigeon pea, Mucuna seed).

Its use in Nigerian agriculture could be justified purely on its nitrogen-fixing capacity if this were found to be superior to other crops. It is this particular aspect which will be the subject of future investigations on guar.

Biotypes of Potato Wart in Newfoundland

The existence of biotypes of the causal fungus of potato wart, *Synchytrium endobioticum* (Schilb.) Perc., which differ in their ability to attack potato varieties in Europe has been documented by Ullrich[1]. Up to 1962, eight, and possibly ten, biotypes had been distinguished[2].

Potato wart has been known in Newfoundland since 1909 and is now found in all cultivated areas of the Island. It is distinctive in that it attacks a considerable number of varieties[3], such as 'Arran Victory', 'Kerr's Pink', 'Ackersegen', and 'Libertas', which are immune from wart Biotype 1 in Europe and Britain.

Because it was reported that 'Arran Victory' was not susceptible to wart in some districts of Newfoundland, an investigation was commenced in 1959 to see whether potato varieties would exhibit the same reaction to the wart disease in various parts of the province. Since the most significant information was obtained in 1962, the results reported here pertain only to that year.

Eleven potato varieties were planted in wart-infested land at five locations, namely: Bay Roberts, Eastport, Ferryland, Jamestown, and St. Shotts. Eastport was included because farmers in the area had found that 'Arran Victory' always remained free from wart infection. The four other locations were selected to sample representative wart-infested areas in eastern Newfoundland. The varieties used were 'Ackersegen', 'Arran Victory', 'Deodora', 'Katahdin', 'Kennebec', 'Kerr's Pink', 'Long Blue', 'Noordeling', 'Sebago', 'Ultimus', and 'Urgenta'. Each variety was planted in two rows of 10 hills each, randomized throughout the plot. The plants were harvested when growth was complete, and wart development was recorded.

Table 1. Varietal Response to Potato Wart Disease at Five Locations

Variety	Eastport	Bay Roberts	Ferryland	Jamestown	St. Shotts
'Ackersegen'	0	+ + +	+ + +	+ + +	Not included
'Arran Victory'	0	+ + +	+ + +	+ + + +	+ + + +
'Deodora'	+ +	+ +	+ + +	+ + +	+ + + +
'Katahdin'	0	+	+	+	+
'Kennebec'	0	+	+	0	+
'Kerr's Pink'	0	+ + + +	+ + + +	+ + + +	+ + + +
'Long Blue'	+ +	+ + + +	+ + + +	+ + + +	+ + + +
'Noordeling'	0	0	0	0	+
'Sebago'	+	+	+	+	+
'Ultimus'	0	0	0	0	0
'Urgenta'	0	0	0	0	0

0, No infection; +, trace infection; + +, light infection; + + +, medium infection; + + + +, heavy infection.

The results are presented in Table 1.

It is evident that the varietal reaction to wart infection was almost the same at Bay Roberts, Ferryland, Jamestown, and St. Shotts, but not at Eastport. Five varieties which were susceptible at the first four locations remained free from attack at Eastport. The most obvious differences were exhibited by 'Ackersegen', 'Arran Victory', and 'Kerr's Pink'.

The wart proliferations developed on 'Deodora' and 'Long Blue' at Eastport were collected for further study in the greenhouse. 'Arran Victory', 'Deodora', 'Long Blue' and 'Sebago' were planted in 7-in. pots of steam-sterilized soil and inoculated by mixing crushed Eastport wart tissue with the soil covering the tubers. Three pots of each variety were grown for two months.

'Arran Victory' remained free from infection, all plants of 'Long Blue' were heavily infected, wart development in 'Deodora' varied from moderate to heavy, and, in 'Sebago', two plants developed light infection, while one remained healthy. Although they were not specifically included in this series, 'Arran Victory' plants inoculated with wart tissue collected from Bay Roberts have regularly become infected in the greenhouse.

Therefore, it is tentatively concluded from the above results that two biotypes of *Synchytrium endobioticum* are present in Newfoundland.

This investigation will be continued to assess the significance of small differences such as the freedom from infection of 'Kennebec' at Jamestown and the trace infection of 'Noordeling' only at St. Shotts, and to determine the distribution of the biotypes in the province.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 26

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. B. Ackner: "Stress and Psychosomatic Disorders".*

MEDICAL RESEARCH COUNCIL (at the National Institute for Medical Research, Mill Hill, London, N.W.7), at 4.30 p.m.—Prof. Sven Gard (Karolinska Institutet, Stockholm): "An Approach to the Study of Virus Synthesis".

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. C. Koeman: "The Life and Work of Lucas Janszoon Waghenaer" (The Eva G. R. Taylor Lecture).

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. K. L. Manchester: "Some Aspects of the Action of Insulin" (Further Lecture on November 2).*

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Prof. A. Rupert Hall: "Galileo and the Science of Motion".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. A. L. Cullen: "Millimetre Wave Examination of Gas Discharges".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.R.E.–I.E.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Colloquium on "Design Automation".

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. Julian Royle: "A Modern Approach to Colour Printing".

ROYAL AERONAUTICAL SOCIETY, HISTORICAL GROUP (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. S. B. Jackson: "The Parachute—an Historical Review".

Tuesday, October 27

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. P. J. Newbould: "The International Biological Programme".*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. C. K. Haswell and Mr. Luis Sancha: "The New Buenos Aires Power Station".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. R. Squire: "Rheumatoid Factor". (Third of fourteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

UNIVERSITY OF LONDON (at the Institute of Archæology, 31–34 Gordon Square, London, W.C.1), at 5.45 p.m.—Prof. Dr. Anders Hagen (Bergen): "Rock Carvings of Norway in the Light of New Discoveries".*

INSTITUTION OF MECHANICAL ENGINEERS, NUCLEAR ENERGY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Achievement of Clean Conditions in Gas-Cooled Nuclear Reactors".

ROYAL AERONAUTICAL SOCIETY, AIR LAW GROUP (at 4 Hamilton Place, London, W.1), at 6 p.m.—Monsieur R. Bulin: "Eurocontrol".

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. W. Simpson: "Glass Transitions and Mechanical Behaviour of Film Forming Polymers".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION, LEA VALLEY SUBSECTION (joint meeting with the Physical Methods Group of the Society for Analytical Chemistry, at the College of Technology, Park Street, Luton), at 7 p.m.—Mr. A. L. Glenn, Mr. A. G. Jones and Mr. F. R. Williams: "Training of the Analytical Chemist in Physical Methods".

Tuesday, October 27—Thursday, October 29

INSTITUTION OF MECHANICAL ENGINEERS, LUBRICATION AND WEAR GROUP (at the College of Advanced Technology, Cardiff)—Meeting on "Iron and Steel Works Lubrication".

Wednesday, October 28

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 4 p.m.—Annual General Meeting. Dr. G. E. R. Deacon, C.B.E., F.R.S.: "Waves and Ships" (Presidential Address).

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. B. C. M. Butler: "A Comparative Study of the Moine Schists of Ardnamurchan with Moine Schists in other Areas of Scotland"; Dr. J. L. M. Lambert: "The Unstratified Sedimentary Rocks of the Meneage Area, Cornwall".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. P. Graystone: "Dynamics Applied to Weather Forecasting" (Sixth-form Lecture).

FAUNA PRESERVATION SOCIETY (at the Offices of the Zoological Society of London, Regent's Park, London, N.W.1), at 5.30 p.m.—Colonel C. D. Trimmer, D.S.O.: "Wildlife Management in Uganda".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. C. H. Flurscheim: "Development in Power Engineering" (Chairman's Address).

UNIVERSITY OF LONDON (at Charing Cross Hospital Medical School, 62–65 Chandos Place, London, W.C.2), at 5.30 p.m.—Prof. C. G. Schmiterlöw (Stockholm): "Physiological Disposition and Biotransformation of C14-labelled Nicotine".*

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Sven Gard (Karolinska Institutet, Stockholm): "Virus-Induced Leukæmia".*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.R.E.–I.E.E. ELECTRO-ACOUSTICS GROUPS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Symposium of Short Papers on "Magnetic Circuit Design Applied to Electro-Mechanical Transducers".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Sir Frank Mason: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP—NUTRITION PANEL AND FOOD ENGINEERING PANEL (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. S. K. Kon, Mr. H. A. Burton and Mr. J. Shacklady: "The Effect of Processing on the Nutritive Value of Foods, Part 1—Liquids".

Thursday, October 29

CHEMICAL SOCIETY (at Queen Mary College, Mile End Road, London, E.1), at 2 p.m.—Symposium on "The Chemical Significance of the Mössbauer Effect".

INSTITUTION OF CIVIL ENGINEERS, HYDROLOGICAL GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Run-off Measurement" introduced by Mr. J. K. C. Wilson.

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Hollow Beams" opened by Mr. A. H. W. Beck.

GLACIOLOGICAL SOCIETY (in Room 105, Roderick Hill Building, Imperial College, London, S.W.7), at 5.30 p.m.—Mr. John Sheard and Mr. Howard Lovenbury: "The Glaciological Work of the 1963 Imperial College Beerenberg Expedition".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. R. D. Harkness: "Some Aspects of the Metabolism and Function of Collagen". (Fourth of fourteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

UNIVERSITY OF LONDON (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 6.30 p.m.—Dr. Harold Blakemore: "Latin America: Past and Present. Indian Civilization: Mexico and the Aztecs".

Thursday, October 29—Friday, October 30

INSTITUTE OF BIOLOGY (in the Lecture Hall, Royal Geographical Society, Kensington Gore, London, S.W.7), at 10 a.m. daily—Symposium on "The Biological Significance of Climatic Changes in Britain".

Friday, October 30

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. R. King: "Radiation 'Damage'".

Saturday, October 31

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. David Morris: "British Reptiles and Amphibians".*

Monday, November 2

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. E. R. Leach: "What Are Social Anthropologists Trying To Do?"

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (joint meeting with the Royal Aeronautical Society, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. I. Kanter: "N.A.S.A. Research and Technology Programmes in Space Navigation".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (joint meeting with the Science and General Division, at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. J. Ellison: "Modern Introduction to the General Theory of Electrical Machines".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Lost Sahara" (Colour films with commentary and introduction by Mr. A. R. Hanbury-Tenison and Mr. James Wellard.)

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. A. Hart: "Research Project Evaluation".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Woolwich Polytechnical Chemical Society, at the Woolwich Polytechnic, Thomas Street, London, S.E.18), at 7.30 p.m.—Dr. J. Leggett: "The Photochemical Apparatus of the Chloroplast".

SOCIETY FOR VISITING SCIENTISTS (at the English-Speaking Union, Dartmouth House, 37 Charles Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Computers in Publishing". Chairman: Mr. Richard Clay. Speakers: Mr. C. J. Duncan, Dr. T. A. Margarison and Mr. Fred Simmons.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LIBRARIAN (chartered librarian, preferably with some experience in a university or technical college library)—Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (October 30).

LECTURER (Grade II) IN PURE MATHEMATICS—The Registrar, University of Bristol, Senate House, Bristol, 2 (October 30).

BASIC GRADE PHYSICIST (preferably with previous hospital experience) for duties mainly concerned with physics applied to radiotherapy, and also with the clinical use of radioactive isotopes—The House Governor (A), Charing Cross Hospital, London, W.C.2 (October 31).

LECTURER IN VETERINARY BACTERIOLOGY IN THE DEPARTMENTS OF VETERINARY PATHOLOGY AND VETERINARY BACTERIOLOGY, Royal (Dick) School of Veterinary Studies—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, 8 (October 31).

SCIENTIFIC OFFICER (with first- or good second-class honours in mathematics with statistics, or a diploma in statistics) IN THE STATISTICS SECTION, for duties mainly concerned with the design and analysis of field and laboratory experiments—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (October 31).

SENIOR RESEARCH ASSISTANT (with a Ph.D. or equivalent research experience) IN BIOCHEMISTRY for work concerned with mucoproteins and their biological degradation products—Dr. F. R. Jevons, Department of Biological Chemistry, The University, Manchester, 13 (October 31).

CHAIR OF MATERIALS SCIENCE within the School of Engineering Science—The Secretary and Registrar, The University College of North Wales, Bangor, North Wales (November 2).

LECTURER IN MECHANICAL ENGINEERING, a LECTURER IN MATHEMATICS, and a LECTURER IN STATISTICS—The Principal, Nottingham and District Technical College, Burton Street, Nottingham (November 2).

RESEARCH DEMONSTRATOR (with a special interest in stratigraphy and/or palæontology) IN THE DEPARTMENT OF GEOLOGY—The Registrar, University College of South Wales and Monmouthshire, Cardiff (November 3).

HEAD (with a degree in horticulture or a degree in science with a diploma in horticulture and considerable experience of horticultural teaching, research and specialist advisory work) OF THE HORTICULTURE DEPARTMENT—The Secretary, The West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (November 6).

SENIOR LIBRARIAN (with a good honours degree, preferably in science or engineering, Associate Membership of the Library Association, and preferably experience in a scientific or technical library)—The Academic Registrar, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (November 7).

DIRECTOR (with good experience with scientific digital computers) OF THE COMPUTING UNIT—The Secretary, Battersea College of Technology, London, S.W.11 (November 9).

LECTURER and an ASSISTANT LECTURER IN ELECTRONICS IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Leicester (November 10).

LECTURER (chemical engineer, physicist or mathematician with interests in mass transfer, chemical thermodynamics or statistical mechanics) IN THERMODYNAMICS—The Registrar, University of Leicester, Leicester (November 10).

SECOND CHAIR OF MATHEMATICS IN THE SCHOOL OF MATHEMATICS AND PHYSICS—The Registrar, University of East Anglia, Earlham Hall, Norwich, Norfolk, NOR 05G (November 16).

READER IN AGRICULTURAL BOTANY AND HEAD OF THE DEPARTMENT OF AGRICULTURAL BOTANY, Makerere University College, University of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 20).

LECTURER IN ORGANIC CHEMISTRY, and a LECTURER IN PHYSICAL OR ANALYTICAL CHEMISTRY at the University College, Dar es Salaam, University of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 30).

LECTURER IN PHYSICS—The Secretary of University Court, The University, Glasgow (December 1).

AGRICULTURAL TRAINING OFFICER (with a degree in agriculture, at least five years tropical experience, and preferably a teaching qualification or teaching experience in an agricultural training institute, and a working knowledge of French) in the New Hebrides, to establish and run an agricultural training school teaching the elements of tropical agriculture to junior field staff—The Appointments Officer, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/124/01.

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with a degree (ordinary or general), Dip. Tech. or H.N.C. with chemistry and/or physics as main subjects) with the Age Determination Unit of the Overseas Geological Surveys, to assist in the determination of the ages of rocks by methods based on natural radioactivity and involving physical and chemical methods of analysis, including mass-spectrometry and high vacuum techniques—Officer in Charge, Age Determination Unit (O.G.S.), Department of Geology and Mineralogy, University Museum, Oxford.

ASSOCIATE PROFESSOR (preferably with research interest in vertebrate biology, ecology or behaviour) IN ZOOLOGY—The Chairman, Zoology Department, McGill University, Montreal 21, Canada.

CHEMIST or BIOCHEMIST (with at least a good honours degree in chemistry or biochemistry with research experience in an appropriate field) IN THE ENZYMOLOGY DEPARTMENT, to work on glycoproteins—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

ENTOMOLOGIST (national of the United Kingdom or the Republic of Ireland, with an honours degree in zoology or a relevant subject plus two years postgraduate study in agricultural entomology), in Uganda to carry out surveys and conduct research into pests of crops and stored produce, especially cotton, coffee and cocoa, and to advise on control measures—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/183/07.

JUNIOR RESEARCH ASSISTANT for fundamental research on sorption by molecular sieves—Prof. R. M. Barrer, F.R.S., Chemistry Department, Imperial College, London, S.W.7.

SOLARTRON RESEARCH STUDENT (preferably interested in dynamic analysis of randomly excited systems) IN THE DEPARTMENT OF ENGINEERING—The Professor of Engineering, The University, Leicester.

TECHNICIAN (with good histological experience) to assist with research on the metabolism of water and electrolytes—Dr. J. M. N. Boss, Department of Physiology, Medical School, University Walk, Bristol.

ZOOLOGIST (national of the United Kingdom or the Republic of Ireland, with an honours degree in zoology, and preferably research or other experience in parasitology or a higher degree in zoology) in Kenya, for the supervision of routine helminthological diagnosis, research on problems of helminthiases of livestock especially the bionomics of nematode and trematode infestations—The Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 217/95/010.

Why pick the Old Equitable?

Here are three simple reasons: efficient management, no commission expenses, and the fact that this life assurance office has no shareholders to take any part of the profits.

1 The Old Equitable, the oldest mutual life office in the world, is today a modern, highly efficient assurance Society. Management expenses are exceptionally low.

2 The Old Equitable pays no commission for the introduction of business, and thus saves large sums for the benefit of its policyholders.

3 Since the Society is run on mutual lines and has no shareholders, the profits belong entirely to its members.

Taken together, these three facts enable the Old Equitable to offer you outstandingly good terms for life assurance, plus excellent bonuses.

If you would like more specific information about the policies available, together with the booklet "Equitable Assurances", please fill in the coupon below.

APPOINTMENTS VACANT

MACQUARIE UNIVERSITY
SYDNEY, AUSTRALIA
APPOINTMENT OF FIRST PROFESSORS

Applications are invited for appointment to the first Chairs established in the University.

Salary for the positions will be £A4,595 per annum plus cost of living adjustments (at present £A42 per annum) and will be subject to superannuation deductions, but may be subject to review in the near future. The successful applicants may elect to contribute either to the New South Wales State Superannuation Scheme or to an F.S.S.U. type of superannuation scheme. There will be provision for sabbatical leave and long service leave. A staff Members' Housing Scheme will be established and in cases approved by the University and its bankers, married men may be assisted by loans to purchase a house.

The University plans to commence graduate and undergraduate teaching on the campus at North Ryde, Sydney, at the beginning of 1967, and to provide for the enrolment of 10,000 undergraduates within a period of ten years thereafter.

It is envisaged that there will be four main components in the academic structure of the University. These will be:

A. A College of Graduate Studies.
B. An Undergraduate College of Arts and Sciences.
C. An organization for Part-time and External studies.
D. Professional schools, for example of Medicine and Agriculture.

As yet no professional schools have been planned. This advertisement relates to responsibilities under the first three headings.

The Council envisages the award of three sorts of first degree:

(i) A Bachelor's degree at honours standard, allowing considerable concentration in a subject or related group of subjects studied at a high level.
(ii) A specialist pass Bachelor's degree akin to the honours degree in respect of concentration but taken at a somewhat lower level.
(iii) A general Studies pass Bachelor's degree in which the student's work is spread over a wider range of studies than in (i) and (ii) with the aim not of producing for example a Chemist, or Historian, a Physicist or an Economist, but a broadly educated person who might enter administration, teaching, librarianship, journalism, etc.

The initial organization of studies will be in schools. These schools will not be as broad in their scope as those which have been established in some other new universities. The intended scope of schools at Macquarie University is indicated in the following tentative divisions :

1. Mathematics and Physics.
2. Chemistry, Biochemistry.
3. Biological Sciences.
4. Earth Sciences and Soil Sciences.
5. English Studies.
6. Historical Studies, including Philosophy and Political Sciences.
7. Foreign Languages.
8. Classical Studies.
9. Economic and Financial Studies.
10. Behavioural Social Sciences (Psychology, Anthropology and Sociology).
11. Educational Studies.

The University looks for applicants who will be interested in participating in the planning of its activities within the structure stated above. It will commence by filling some six chairs in a range of disciplines which includes Mathematics, Physics, Chemistry and Psychology.

The University reserves the right to fill any position by invitation.

Further particulars and information as to the method of application should be obtained from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

Applications close in Australia and London on November 3, 1964.

PARKE-DAVIS

(a) A Ph.D. or HONOURS GRADUATE

is required by the Chemical Research Department to work on the synthesis of organic compounds of potential therapeutic interest.

(b) AN HONOURS GRADUATE

is also required by the Product Development Department for the development of organic chemical compounds of potential chemotherapeutic use.

The terms of employment with the Company are attractive, they include a 5-day, 37½-hour week, generous pension and life assurance plan, staff restaurant.

Please apply

Personnel Manager,
PARKE, DAVIS & COMPANY,
Staines Road, Hounslow, Middlesex

BARR AND STROUD

FILTER AND NETWORKS DESIGNER

Due to expansion of the Networks and Filters Section in our Electronics Laboratory, applications are invited from Electrical Engineers, Physicists or Mathematicians with some years of experience in this field, who should be capable of taking a leading part in the design and measurement of RC, LC and crystal networks for use in a wide variety of applications.

The Works are situated in the West of Glasgow, north of the river and near the City Boundary. There is thus easy access to the Firth of Clyde and West Highlands; with all this brings in opportunities for sailing, climbing and skiing. Educational facilities are excellent, both in schools and technical colleges and universities.

Apply, stating age, training and experience, to:

The Personnel Manager,
BARR AND STROUD LIMITED
ANNIESLAND, GLASGOW, W.3.

UNIVERSITY OF EAST AFRICA
THE UNIVERSITY COLLEGE,
DAR ES SALAAM

Applications are invited for the Chair of Geography, a newly established post. Appointment may be taken up in January, 1965, or as soon as possible thereafter. The post carries the responsibility for planning the syllabus in the Faculty of Arts and Social Science. Salary: £2,800 per annum. Expatriation Allowance £500 per annum. Permanent or Contract Terms (contract terms carrying 15 per cent gratuity). F.S.S.U. For Expatriates: Education Allowance. Housing at subsidized rental. Economy class air passages for appointee and family (up to five adult passages) on appointment, termination and leave (three months every 21 months).

Detailed applications (eight copies), naming three referees by November 30, 1964, to Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1, from whom further particulars may be obtained.

UNIVERSITY OF SINGAPORE

Applications are invited for (A) Lectureship or (B) Assistant Lectureship in Biochemistry. Salary scales : for medically qualified candidates (A) £1,295 by £49 to £1,442/£1,540 by £56 to £1,988 per annum, (B) £1,148 by £49 to £1,246 per annum. For non-medically qualified candidates (A) £1,148 by £49 to £1,442/£1,540 by £56 to £1,820 per annum, (B) £1,001 by £49 to £1,099 per annum. Entry point determined by qualifications and experience. Allowances : expatriation in range £280 to £308 per annum, cost of living temporary) in range £210 to £560 per annum. Passages for appointee, wife, and children not exceeding 12 years. Partly furnished house/flat at reasonable rent. Provident Fund Scheme.

Detailed applications (8 copies), naming three referees, by November 30, 1964, to Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1, from whom further particulars may be obtained.

RESPONSIBILITY AND EDUCATION

TOWARDS the close of his presidential address to the British Association for the Advancement of Science (*Nature*, 203, 943; 1964) at Southampton, Lord Brain urged that one of the consequences of the population explosion was that, so far as we could, we should prepare all our people for a new world which would be quite unlike the old. This would mean spending more money and thought on education than we do at present, remembering that the best educational results were unlikely where home conditions were bad. In this context he saw education to-day as having two tasks, one of which was to prepare people for leisure.

First, however, education must concern itself with the whole individual and therefore with behaviour, and here it must largely reflect the views and standards of society. One of our needs as a society, now predominantly secular, is to develop a code of social responsibility which could form an integral part of education. Whether by design or coincidence, this note of responsibility was dominant in the discussions in Section L (Education) at the Southampton meeting of the British Association. The president of Section L, Dr. F. Lincoln Ralphs, dealt first with responsibility and education as the combined mainspring of our continuing evolution (*Nature*, **203**, 954; 1964) Those who followed discussed successively the particular responsibility of the Press, the State, the universities, the parent and the school, the teacher, the Church, the architect, industry and television.

Dr. Ralphs himself was more especially concerned with the changes in our conception of responsibility in relation to education in the past two decades and in the context of the 1944 Education Act. He began with a brief survey of the way in which the sense of responsibility in education had quickened during the previous two generations. Inevitably he touched on fields that were covered by succeeding addresses, but although he found it impossible to consider responsibility and education in the context of the 1944 Act without reference to the remarkable emphasis it placed on religion and worship, there was virtually no overlapping with Mr. Leslie Paul's paper on the responsibility of the Church. Mr. Paul was concerned first with the organizational and social responsibilities of the Church, and then with the spiritual contribution which the Church might make to the tone and content of contemporary education. Dr. Ralphs, however, was concerned with challenging our emphasis on the species rather than the individual, and our failure to develop a society sufficiently inspired by ideals of service and increasingly uncertain about the purpose of life.

Quoting Prof. Butterfield's view in *Christianity and History* that only the Christian view (that each individual soul has eternal moment and has value incommensurate with the value of anything else in the created universe) offered a firm barrier against the emphasis on species, Dr. Ralphs stressed the implications of the religious clauses of the Act. After welcoming their increasing recognition by the Churches, he reminded us that the way in which, in the post-war period, individuals had been ruthlessly urged towards conformity was an affront to human dignity. There was some reason to fear that our barriers against Hitler's prodigality with the individual lives of men and women were down and might not be put up again in time. In our recognition of educational responsibility we needed to realize where we were going.

Dr. Ralphs's address abounded in illustrations of this point. He reminded us once again that intelligence is not increased by legislation, though the opportunity for its development may be. Is this sufficiently appreciated in plans for the expansion of higher education, especially at university level? Or again, is it not true, as he suggested, that we lack imagination in planning new enterprises and tolerate subject specialization leading to academic awards or to apprenticeships that are anachronistic in an age of automation? Failure to think imaginatively and creatively may represent as gross a dereliction of responsibility as flat repudiation.

One of the most serious criticisms of education to-day is that for so many it becomes boring, as do the jobs in which they will have to earn their living. No greater reproach can be levelled against a course or an institution than that it kills the desire to learn, and, as Dr. Ralphs observed, we need constantly to remind those entering the teaching profession that the first function of a teacher is not to instruct but to inspire. This has to be remembered when we tend to measure educational needs in terms of thousands of teachers to be recruited: neither inspiration nor intelligence is mass-produced, though, especially with the former, environment can sometimes be decisive.

Here, however, we must admit that this generation has not been markedly successful in training its adolescents to be aware of the full consequences of their actions. Large classes, and the increasing emphasis on factual knowledge which examinations tend to encourage, are scarcely calculated to inspire the acceptance of responsibility, and Dr. Ralphs believed that irresponsibility has never before been so heavily subsidized. This may be due in part to a confusion in the concepts of discipline, but the traditional belief that education should be endured rather than enjoyed still persists. Dr. Ralphs commented trenchantly that, in education, certificates all too often tend to become documents announcing one's arrival, not single tickets entitling one to travel, or certificates of work-worthiness in responsible enterprise. "If we fail to develop, with our increasing erudition, a matching sense of personal responsibility, the nineteenth century, which died in fear of ignorance, may have done no more than pave the way for the twentieth century to perish in the fear of knowledge".

It is a commonplace to-day that progress depends on the use rather than the possession of knowledge, and while our sense of responsibility demands education for the individual, our education must demand individual responsibility. Whatever criticism may be used of the evidence submitted by the National Union of Teachers to the Central Advisory Council for Education under Lady Plowden's chairmanship, that evidence attests the deep sense of responsibility that pervades the Union: indeed, that is manifest in the very failure to reach common agreement on matters relating to the transition from primary to secondary education. Sir Ronald Gould's address to the Section on August 31 showed this sense of responsibility no less clearly.

Dr. Ralphs then spoke of the responsibility of the State for education. If the individual was to be protected

against all the pressures of a technological society which threatened his individualism, the State's share should be concentrated in efforts to provide for local and individual initiative rather than to prescribe patterns and programmes. Irresponsibility, he remarked, grows all too easily in centralized systems of remote control, whether in industry or in education, and he hoped that in education we would always remain a little suspicious of central control at any level. The point could scarcely be illustrated better than by the past Government's ill-judged and short-sighted attempt at economy in adult education against which the Universities Council for Adult Education protested firmly and with dignity in its statement *Crisis in Adult Education*.

Dr. Ralphs admitted that a more comprehensive view was possible at the centre and that we must accept the responsibility for making the best use of resources, though in the changes we made we must safeguard the effective use of the time and initiative of teachers. Individual initiative arising from personal responsibility, encouraged and accepted, not frustrated by restrictions, was one of our most valuable resources, and, whether from teacher, parent or pupil, flourished best when authority was delegated rather than centralized. Sir Herbert Andrew, in his address on August 28, did not appear to dissent. He thought it inevitable that an increasingly well-informed public opinion would bring more constructive and sympathetic criticism to bear on the educational system, to which the teacher and administrator must respond.

Dr. Ralphs pointed out that the 1944 Act placed the responsibility for the education of children fairly and squarely on the parents, although they could call on the community for help if necessary, and for the vast majority of parents such help is essential. Moreover, in general, the aid is most effective when, as in the public schools, it is sought and seen as a sharing of responsibility and not as a State service provided as of right and on demand. Some parents undoubtedly saw the Education Act as a declaration of rights rather than as a definition of duty, and Dr. Ralphs admitted that there will be differences of opinion as to the extent to which we should, or shall be able to, effectively and properly involve parents in this responsibility for education. Nevertheless, he was firm that we cannot divorce education from responsibility without endangering the community, and to-day it is a world community that is involved.

On these points Dr. Ralphs was firmly supported by Mr. Michael Young in his paper on the responsibility of the parent and the school, for Mr. Young's suggestion for an education welfare service is intended to foster just this sense of responsibility and its discharge. The proposal is tentative and Mr. Young emphasized the need for more evidence of the kind that only research can provide. A main purpose of the education visitors, he suggested, would be to arouse the interest and sense of responsibility of the parent. Whether such association of parents with the work of the school does, in fact, assist the progress of the child at school remains to be established.

Dr. Ralphs recognized that radio and television have already made valuable contributions to the instruction of parents, but the educational potential of mass media was discussed in subsequent papers by Mr. J. Beavan and Mr. Kenneth Aden, and Dr. Ralphs contented himself with the pertinent comment that, as with the teacher, their educational influence extends to all their activities and cannot be restricted to those they choose to describe as educational. Viewed as a whole the mass media seemed to Dr. Ralphs to contribute to the present-day practice of requiring schools to advocate standards the outside world has little mind to honour. We have much more to do than to raise the school leaving age, and Dr. Ralphs did well to remind us that the standards of the street are as influential as the conduct of the classroom.

We cannot ignore the influence of the totality of our environment, and neither teacher nor parent can escape the continuous responsibility that attaches to their private lives. We teach what we are no less than what we know, and if this explains why we tend to prefer instruction to teaching and accept erudition in place of education, it does not excuse either the preference or the acceptance. More or less consciously the issue is linked with the debate over commercial television and broadcasting and with advertising on television; Mr. Beavan at least recognized the implications in discussing the responsibility of the Press. If he was concerned to defend the freedom of the Press, he was equally concerned to maintain that comment must be responsible and proved error admitted promptly and without equivocation.

On the responsibility of the Press in education, which he frankly admitted, Mr. Beavan was concerned particularly with the difficulties that a responsible newspaper encountered in pursuit of its idea that it should help to make good citizenship possible by providing adequate political information, even though it was also an organ of entertainment. He thought the development of the specialist report was a factor making for increased responsibility, but the great problem of a newspaper was to keep its readers interested, and though a sizable minority of the adult population read thoroughly the serious items, most readers either did not read them thoroughly or did not read them at all. Nevertheless, he thought that as more people were educated to a later age, newspapers, aided by television, could hope to increase the following of serious events.

Dr. Ralphs concluded his address on a like note of optimism. The future, he said, is increasingly in the hands of youth, who, in spite of unprecedented inducements to delinquency, were for the most part eminently sensible and imbued with the desire to do their best. Obviously, in his view, youth is responding to the challenge of responsibility so clearly thrown down by the Robbins Report, and a certain note of caution in Mr. H. L. Elvin's address to Section L on August 28 did not conceal the frank acceptance by the universities of their own share of responsibilities. It is indeed only fair to point out that that sense of responsibility is the real cause of some of their reservations and hesitations as to the *tempo* and character of proposed plans for expansion, and what Dr. Ralphs said earlier in his address about compulsion and conformity applies with as much force here as anywhere.

The whole series of papers presented to Section L (Education) at the British Association meeting at Southampton served to display the full range of interlocked responsibilities in education and the need for continuing co-operation, understanding and experiment. Progress is not furthered by unreasonable questioning of the good faith of those who differ as to the timing or magnitude or character of proposed measures, any more than by refusing to recognize difficulties or awkward facts and situations. The whole series of papers represents a material contribution to a wider general understanding and a stimulus to the good will that is equally essential.

CIRCADIAN ORGANIZATION

The Physiological Clock

Endogenous Diurnal Rhythms and Biological Chronometry. By Erwin Bünning. Pp. vi+145. (Berlin: Springer-Verlag, 1964.) 19 D.M.

THIS English translation of the second (1963) edition of "Die Physiologische Uhr" has been brought up to date by the author and is quite indispensable for any biologist interested in the rhythmical aspects of organisms and their manifold theoretical and practical implications. It is more comprehensive and less controversial than other recent books and reviews of the subject. Although it cannot rival the bulk of information presented at three symposia held during the past few years (25th Cold Spring Harbor symposium, 1960; 39th Ross Conference on Pediatrics, Ohio, 1961; Conference on Biological Rhythms of the New York Academy of Science, 1962), it has the advantage of being written by a single author, who has been working on the subject for more than 30 years.

The old-fashioned title of the book should not mislead the reader into believing that endogenous rhythms of approximately 24 h period length can only be produced by highly specialized machinery, such as the neurocrine systems of vertebrates and arthropods or the joints of leaves of higher plants. Bünning makes it abundantly clear that oscillations which Halberg (1959) has named circadian (from circa diem, about a day) occur at most levels of organization, in fungal mycelia and unicellular algae, in birds and flowering plants, and in the social organization of the bees and of man. They affect a multitude of metabolic, locomotor, epigenetic and sexual activities, can be demonstrated by measuring all sorts of parameters and in Nature are synchronized by physical, chemical, biological or social cues, which all derive from the rotation of the Earth. The length of time a circadian rhythm may persist after removal of rhythmic time cues depends on the kind of organism, the function observed and certain environmental factors. According to the different degree of centralization of flowering plants and higher animals a small part of a leaf may show an endogenous rhythm of about 24 h in its CO_2 output, whereas an isolated limb, organ or tissue of a metazoon is unlikely to show any trace of circadian rhythm—with the possible exception of larger parts of the nervous and endocrine systems, which are the 'masterclocks' of these organisms.

The kinds of time cues or synchronizers, the degree of autonomy and interdependence of the various behavioural and organ rhythms, and many interactions of the circadian organization not only with diurnal rhythms but also with the tidal, lunar and seasonal fluctuations, form the principal subject matter of Bünning's book. While to a superficial glance this may appear as somewhat of a medley, it will repay the reader to follow the author's lead when he tries to fit this diverse material into the mathematical, physiological and ecological generalizations which, as his own experimental successes have shown, have considerable predictive power.

Bünning's book indicates one of the profound but nearly imperceptible 'sea changes' in biology; one which is about to sweep away many cherished, and in their time beneficial, concepts of nineteenth-century physiology. One of these is excessive biological atomism, the idea that 'in the end' life will be explicable in those chemical and physical concepts which are derived from the results of isolating and destructive methods. Obviously the study of organization, circadian or otherwise, does not lend itself to this approach. To paraphrase an old gibe: when dissecting an animal a biological clock, like the mind, is just not among the organs, though—again like the mind—time-keeping may have a decided affinity to special organs.

Another change concerns the concept of homœostasis, Claude Bernard's grand idea which in its petrified form has been for half a century a millstone round the neck of physiologists, clinicians and even geneticists. The conviction that 'the organism' strives at maintaining many physiological parameters at a constant level has blinded biologists to the universal existence of oscillations and their functions and also has distorted the aims of some laboratory practices and of therapeutic procedures. Constant temperature or illumination—though compatible with the bare existence of many domesticated strains in insects, rodents or birds—nevertheless introduces strains of their lives and does not produce specimens which are suitable for a host of behavioural experiments. The relative disregard (compared with such obvious factors as heat, hunger or infection) of the importance of the hour of the day for personal habits, shift work, hospital ward practice, or air travel has been at the root of much distress. It all stems from neglecting man's circadian organization, which to such 'quacks' of the eighteenth-century as Hufeland was one of the fundamentals of health. With the improvement of research methods the time aspects of life, and the ever-widening field of their application, are becoming increasingly important; over half an insulin dose can be saved for certain patients by administering it at the right hour: pheromones produced by the females of some moth species attract the males only during the three hours after midnight: the success of growing chrysanthemums and of producing eggs depends to a considerable extent on the light regimen during the day's 24 h—and so on.

It is perhaps paradoxical that the advent of the space age should coincide with the renewed interest of biologists in such old-fashioned terrestrial phenomena as the days, the tides and the seasons; and that some of their work should be supported by funds for space research. But, just as rockets and satellites have revived interest in celestial mechanics, so does the prospect held out by these vehicles of facing life without the accustomed changes of the hours or seasons revive interest in the potentialities and constraints which are the consequence of the circadian organization of ourselves and our fellow creatures.

H. KALMUS

ASPECTS OF CORTICOSTEROID STRUCTURE AND METABOLISM

Structure and Metabolism of Corticosteroids

Edited by Jorge R. Pasqualini and Max F. Jayle. (Proceedings of a Symposium held in Paris, 5–6 July 1963, and organized by the Faculté de Médecine, Laboratoire de Chimie Biologique.) Pp. x+168. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 35*s*.

THE collection of sixteen papers which constitute *Structure and Metabolism of Corticosteroids* follows no well-defined pattern, and the editors have not found it an easy task in deciding on the best grouping to adopt in preparing it. Part 1 dealing with structural problems has only two chapters, a detailed account by Caspi of work at the Worcester Foundation in which he emphasizes the usefulness of nuclear magnetic resonance spectra, and a contribution by Kellie on the means of differentiating between two types of conjugate, for example, C_3- and C_{21}-glucuronosides.

The largest set of contributions are those in Part 2 entitled "Corticosteroid Metabolism in Vivo and Vitro", where we find much more on the subject of conjugation. Oertel adduces here further evidence to support his previously published work on those non-polar solvolysable steroid conjugates styled "sulphatidyl" steroids. Conjugation in urine and plasma is also the topic dealt with by the joint editors, who have accumulated an impressive array of evidence on which to formulate a set of rules governing the relationship between structure and type of conjugation. Sulphate conjugation is the subject of the paper by Tamm and Voigt, who offer an explanation of the curious

finding that excretion of cortisol 21-sulphate follows the oral administration, but not the intravenous infusion, of large doses of free cortisol. Vermeulen, examining the metabolism of certain anabolic steroids, finds that some testosterone derivatives decrease cortisol metabolism while others do not, and he puts forward the hypothesis that the difference in the two classes might depend on the route of excretion of the administered steroid. The feed-back theory which ordinarily accounts for the homœostatic control of plasma cortisol-levels is seen by James and Landon to be inadequate to explain the elevation of plasma cortisol in conditions of stress. They describe conditions under which stress will release adrenocorticotrophic hormone independently of the circulating steroid concentration. A chromatographic method using glass-fibre paper is described by De Hertogh *et al.* for the analysis of plasma cortisol, corticosterone and cortexolone. It should have a special interest for clinical biochemists.

Among other papers in the same section is one showing a difference between the *in vitro* and the *in vivo* incorporation of corticosteroid in sub-cellular particles of heart and kidney cortex; another indicates a synthetic route to aldosterone starting from the alkaloid holarrhimine. Aldosterone metabolism is dealt with by Pasqualini.

The final part of the volume is devoted to pathological considerations and includes an account of the metabolism of cortisol in Cushing's syndrome and of aldosterone in renal insufficiency. Cost evaluates urinary steroid excretion patterns and re-examines published ideas about the significance of 11-deoxycortisol compounds (compounds S and THS) in relation to the diagnosis of primary adrenocortical carcinoma. Combined histological and biochemical observations are the basis of Grant's paper on transformations accomplished by tissue taken from different zones of the adrenal cortex.

Those specially concerned with corticosteroids are bound to find some, but by no means all, papers in this volume meriting their close attention. J. Patterson

SYNAPTIC PHYSIOLOGY

The Physiology of Synapses

By Prof. John Carew Eccles. Pp. xi+316. (Berlin: Springer-Verlag, 1964.) 36 D.M.

THE understanding of nervous activity depends on our grasp ot two matters, the pattern of interconnexion between cells and cell masses, and functional result in a given cell of the arrival of activity at any particular presynaptic ending. The microanatomy of the nervous system got off to an early and propitious start largely due to the brilliance of Cajal, and although many details of nervous anatomy remain obscure the basic patterns have been known for nearly half a century. On the other hand, the study of synaptic events remained unproductive until the discovery of the intermediary local synaptic potential at the neuromuscular junction. There followed the development of precise biophysical methods for recording synaptic events and for analysing the site and mechanism of action. The main object of this book is to present a critical account of the synaptic areas so far investigated. One of the features discussed is whether transmission is due solely to local current flow or whether it involves the mediation of chemical agents, and Eccles describes the criteria that must be used to make this distinction. While the evidence points conclusively to the chemical nature of the majority of synapses, there is now equally conclusive evidence that some synapses are purely electrical, and there is even an interesting dual mechanism in the ciliary ganglion of the chick in which both processes may play a part. Perhaps one of the most interesting findings in recent years is that, while there is considerable stereotypy in synaptic patterns (for example, the post-junctional effects of all the chemically mediated excitatory junctions appear very similar), there is also available a considerable variety of synaptic types, so that similar final effects may be produced by unrelated mechanisms. For example, inhibition may be produced by a direct action of an inhibitory transmitter on the post-synaptic membrane, causing increased chloride permeability, or it may be produced presynaptically by depolarization of the presynaptic excitatory fibre, thus depressing its ability to release excitatory transmitter. While both these processes will, for example, depress the response of anterior horn cells to primary excitatory afferents, the net result is significantly different. In the first case the inhibiting post-synaptic potential is competitive with all incoming excitatory impulses; but in the second case, because the effect is produced presynaptically, no interference occurs other than with excitation from the presynaptic fibre that is affected. In other words, the second process is a much more selective one. This kind of distinction may have considerable significance in overall nervous integration. One of the most interesting of the newer functional processes is the electrical inhibitory synapse on the Mauthner's cell of goldfish, discovered by Furukawa and Furshpan. In this instance the presynaptic fibre is coiled around the axon hillock of the Mauthner cell and acts as an external source of hyperpolarizing current. In some respects this is reminiscent of the old hypothesis of inhibition by currents generated by Golgi Type II cells. In contrast to the precision with which post-synaptic events can be measured and the mechanisms of the membrane changes delineated by ion injection and by passage of current, our knowledge of presynaptic processes seems meagre. It is probable that transmitter release is highly dependent on membrane depolarization at the terminals, but how this effects release is obscure. The main reason for this deficiency lies in the great technical difficulties in the way of carrying out direct investigations on presynaptic fibres owing to their small size. An even greater disappointment to all interested in synaptic physiology has been the failure to elucidate the nature of any chemical transmitter in the mammalian nervous system other than acetylcholine. It is a sorry situation that despite considerable effort we are totally in the dark as to the chemical transmitter at the primary sensory afferent fibres, and both presynaptic and post-synaptic spinal cord inhibitory systems, not to mention other areas. Sooner or later one hopes that the blunderbuss approach being pursued at present will lead to a breakthrough, but there is really little sign of this so far. Another area in which the result has not been dramatic is the investigation of synaptic plasticity, although this is a vital topic for the understanding of the developing nervous system. The rapid advance in the understanding of synaptic processes has not as yet had much impact on the examination of complex neurophysiological or behavioural phenomena, mainly because there are so many problems of organization still to be solved, but it is surely only the faint-hearted who are not convinced that exact descriptions of such processes are now feasible. Indeed, for all who are interested in the analysis of nervous processes this learned and lucid book is indispensable, and will remain so until superseded by Eccles's next book.

A. S. V. Burgen

CARBOHYDRATE CHEMISTRY AND BIOCHEMISTRY

Advances in Carbohydrate Chemistry

Vol. 18. Edited by Melville L. Wolfrom and R. Stuart Tipson. Pp. xi+456. (New York and London: Academic Press, 1963.) 118*s*.

WHATEVER his or her specialization, every carbohydrate chemist or biochemist will find something of direct interest in the latest edition of this standard

work. The many developments in paper electrophoresis since the first account six years ago are reviewed by H. Weigel, to illustrate this valuable adjunct to chromatography as a means of separation on a micro or preparative scale. Elizabeth F. Neufeld and W. Z. Hassid record for the first time in this series the knowledge of nucleoside diphosphate sugars, now recognized as the major type of poly- and oligo-saccharide precursor in biosynthesis. The discovery of these substances, originating with L. F. Leloir *et al.*, was the foremost event in carbohydrate biochemistry in the past decade, and the impetus of this discovery is still at its height. The article was written before Hassid himself reported the conquering of the plant biochemist's 'Everest', the biosynthesis of cellulose, where the precursor proved to be guanosine diphosphate glucose (Elbein, Barber and Hassid, *J. Amer. Chem. Soc.*, 86, 309; 1964). Having regard to the claims of cellulose to be the most abundant organic compound, GDPG must be one of Nature's most hard-working substances. About 3 kg were required to make the paper on which each copy of Volume 18 of *Advances in Carbohydrate Chemistry* is printed.

C. T. Greenwood, with W. Banks, continues to record the physical aspects of polysaccharides, this time their solution behaviour. D. Horton and D. H. Hutson review thio sugars for the first time since Volume 1 and record another long-sought goal, achieved in two British laboratories in 1961, that of synthesizing sugars with sulphur replacing the ring atom. Other compounds that begin to look less and less like carbohydrates are the amino sugars of antibiotics. J. D. Dutcher reviews this very active field. Two groups of naturally occurring compounds not previously reviewed here are the trehaloses (G. G. Birch) and *C*-glycosides (L. J. Haynes), and the list of articles is completed with photochemistry of carbohydrates (G. O. Phillips) and osotriazoles (H. El Khadem), the latter compounds being cyclization products of osazones. J. E. Courtois contributes an appreciation of E. Bourquelot (1851–1921), and the editors' preface reminds us that we shall expect an obituary notice of J. C. Sowden, for long an adviser to the series.

No sales promotion will be needed to sell this volume. It is as indispensable as its predecessor in its wide-ranging and detailed coverage. M. L. Wolfrom and R. S. Tipson, the editors, themselves responsible for no mean part of the annual output of carbohydrate research, deserve the warmest praise for their efforts in ensuring the prompt annual appearance of these meticulously prepared volumes.

W. J. Whelan

BEHAVIOUR IN INFANCY

Cerebral Function in Infancy and Childhood

By Prof. Albrecht Peiper. (The International Behavioural Sciences Series.) Translation of the third revised German edition by Benedict Nagler and Hilde Nagler. Pp. xii + 683. (New York: Consultants Bureau, 1963.) 25 dollars.

At a time when pædiatricians in Great Britain and the United States have at last become intensely interested in the behaviour of the infant, and especially the new-born infant, the appearance of a translation of Prof. Peiper's monumental account of previous investigations of behaviour in childhood must be warmly welcomed.

Cerebral Function in Infancy and Childhood is a translation of the third edition of the author's *Die Eigenart der kindlichen Hirntätigkeit*, which appeared in 1961 and was based to some extent on his earlier book *Die Hirntätigkeit des Sauglings* of 1928. In it Prof. Peiper gives an account of previous work describing the behaviour of children which he considers to be relevant and scientifically sound. He defines his attitudes to investigations of child behaviour in the prefaces and the first chapter of the book. He is concerned with "the emergence of brain function" in infants and young children as it is manifest in their spontaneous behaviour in test situations. He feels that anatomical investigations and child psychology have been unproductive in examinations of child behaviour, though some physiological animal experiments have given information relevant to the young child, particularly those of Pavlov, Magnus, Radermacker, von Holst and Von Uexküll. He insists on observations being objective and is intolerant of explanations of behaviour in terms of child's consciousness, awareness or emotions. He states on p. 1: "Man knows his own brain functions from inner experience and self-observation, the brain function of others only from observation. As infants and animals are not able to observe themselves and report upon their observations, insight into infant and animal psychology can be gained only by observing their behaviour. This methodology has been accepted in the field of animal psychology and has been found very productive, but it still remains very foreign to the field of infant psychology. Infant psychology should therefore model itself on animal psychology in this respect. 'The soul of infants differs, so to speak, in nothing from the soul of animals'."

There follow fourteen chapters in which a most detailed account is presented of many aspects of child behaviour. The headings of some of the chapters give some idea of the scope of the book. They include: "The Development of Sensory Function"; "Reflexes of Position and Movement"; "Locomotion"; "Movements"; "Reflexes of Clinical Significance"; "The Neurology of Food Intake"; "Conditioned Reflexes"; "Neurological Characteristics of certain Developmental Phases"; "Evolution and Dissolution of Cerebral Function"; and "The Child and his Environment". These give an amazingly full account of 100 years or more of German work in the investigation of child behaviour, together with the highlights of British, French, Russian and American research. Some 1,700 authors are quoted in the author index, and their work is fully described and discussed in the text with a command and sense of proportion which indicate Prof. Peiper's mastery of the subject.

Prof. Peiper's sense of historical perspective enables him to present accounts of the development of ideas as well as to describe actual observations and experiments. The section in Chapter 3 on "Theories of Expression" is a good example of how he is able to show that the ideas of earlier workers, including Spencer and Darwin in this case, were important in determining the course of later research.

Inevitably the book has defects. Many of the controversies he describes are now no longer of interest, and disproportionate attention is directed to observations and experiments which have been superseded by the use of superior modern techniques. The chapters on "The Neurology of Respiration" and "The Neurology of Food Intake" suffer particularly from the author's neglect of recent work, but many examples of this may be given. For example, there is no discussion of the concept of visual fieldedness or of the work of Hildreth in the sections concerned with laterality. Scarcely any non-German references since the Second World War are discussed in the section describing convulsions. The chapter on "The Child and his Environment" gives a fascinating account of wolf children but very little discussion of ideas about deprivation and social environment which have developed since the Second World War. It is apparent throughout the book, however, that Prof. Peiper's knowledge of the world literature since 1939 is limited compared to his encyclopædic knowledge of earlier work. It is sad that a research worker of his eminence should find it difficult to obtain foreign publications.

These are relatively minor criticisms. No one else could have written this book. Prof. Peiper presents a comprehensive account of previous research on child development and

sets it in perspective. It is a book which has long been required and is a completely reliable and knowledgeable description of research work up to the beginning of the Second World War which will remain a uniquely valuable work of reference.

The translation is always adequate though there are a few 'Germanisms', and the book has been very well produced. Inevitably the price is high, but it is likely to be bought by many pædiatricians who until now have had difficulty in finding descriptions of early work on behaviour development.

T. T. S. Ingram

PAPER CHROMATOGRAPHY

Paper Chromatography

A Comprehensive Treatise. Vol. 1, Edited by I. M. Hais and K. Macek. Pp. 955 (1963), 190*s*. Bibliography of Paper Chromatography, 1944–1956, and Survey of Applications, Vol. 2. By Karel Macek and I. M. Hais. Pp. 766 (1960), 171*s*. 6*d*. Bibliography of Paper Chromatography, 1957–1960, and Survey of Applications, Vol. 3. By Karel Macek, I. M. Hais, J. Gasparič, Jan Kopecky and V. Rábek. Pp. 706 (1962), 171*s*. 6*d*. (Prague: Publishing House of the Czechoslovak Academy of Sciences; New York and London: Academic Press.)

THIS work has had a rather complicated history. The first edition was published in the Czechoslovakian language in 1954 and was rightly regarded as the most complete treatise on paper chromatography to be written. The second edition was published in German only four years later, and some time afterwards the Czech version appeared, to be followed by Romanian and Russian translations. The second edition consisted of two volumes: Volume 1 covered principles and applications; Volume 2 was bibliographical, covering the literature from 1944 to 1956. The third edition comprises three volumes. Volume 1 has been brought up to date; Volume 2 is unaltered from the second edition, and Volume 3 has been added to supply bibliography for the years 1957–60. Volumes 1 and 3 are translated into English, but Volume 2 is in Czechoslovakian, although it must have been the intention of the editors to prepare an English translation. There is a separate supplement in English to help the English reader to find his way about this volume.

In both bibliographical volumes, the titles of references are given in their original languages, if in French, German or English—as more than 90 per cent of them are—otherwise they are translated into English. Volume 3 follows the arrangement of Volume 2, the German version of which was reviewed in *Nature* five years ago (184, 1436; 1959), but the editors have been more selective, omitting thin-layer and column chromatography and references in which paper chromatography has not played an important part. Yet the number of references (more than 8,000) for the years 1957–60 compared with some 10,000 for 1944–56 shows that, despite the development of other techniques, paper chromatography continues to hold its own as an analytical tool.

In Volume 1, much of the material of the previous edition has been incorporated unchanged, but there has been some re-arrangement of subject-matter and most of the chapters have been brought up to date. There is a good deal of new material on radioactive substances, peroxides and peroxi-acids, steroid glycosides, terpenes, pesticides, pigments, plastics and intermediates and inorganic substances. The practical notes on detection reagents, solvent systems and quantitation have been usefully extended. Special attention is directed to the relationship between chromatographic behaviour and chemical structure and to the elaboration of solvent systems for the identification of substances on the basis of their chromatographic mobility.

In this volume also, the editors have been more selective than in previous editions. Column chromatography on cellulose derivatives, and electrophoresis, have been omitted, but further pruning would have been desirable, particularly of obsolete material such as the sections on retention analysis, on preparative paper chromatography and on the paper chromatography of proteins. On the other hand, there are a few omissions; for example, the part played by paper chromatography in the discovery of iduronic acid in chondroitin sulphate *B* is not mentioned and the importance of the 'finger print' technique for peptides is not emphasized. The latter is deliberately played down because it involves electrophoresis, yet a fuller account (with photograph) is given of the separation by this means of the amino-acids of blood serum—surely a less important application.

These are, however, comparatively minor criticisms of a work which covers an enormous field with great thoroughness. The English translation is on the whole well done, but the quality of the paper leaves much to be desired. This makes the reproductions of photographs in Volume 1 poor by comparison with the German version, which was printed on good paper. The high price of these volumes will deter many individual prospective buyers, but should not prevent libraries from adding these useful reference books to their shelves.

R. Consden

MATERIALS AT EXTREME CONDITIONS

High Temperature Structures and Materials

Proceedings of the Third Symposium on Naval Structural Mechanics, held at Columbia University, New York, N.Y., January 23–25, 1963. Edited by A. M. Freudenthal, B. A. Boley and H. Liebowitz. (Office of Naval Research Structural Mechanics Series.) Pp. xv+463. (London and New York: Pergamon Press, 1964.) 100*s*. net.

THIS collection of thirteen papers was designed to cover four broad subjects: material aspects of elevated temperature design; effects of high-speed environment; thermal stress analysis; design criteria and reliability. As is stated in the preface: "It was hoped that the collaboration in one conference of material physicists, mechanicians, and structural designers concerned with the problem of elevated temperature effects on the performance and safety of modern structures would at least in part bridge the gaps existing between the three groups". This is a worthy aim, and no doubt much was gained by those who participated in the conference. As a published work, however, the papers cannot be said to carry the bridge-building spirit very far: many of them are fairly specialist reviews, not tailored for general communication (this is particularly true of the more mathematical ones on thermal stresses, and on the thermoelastic boundary problems), while others, good in themselves as technical assessments, fail to carry the arguments to the point where the real nature of the critical problems may be appreciated and discussed in non-specialist terms. Unfortunately it is much harder to write a paper on the lines necessary for a truly interdisciplinary conference than it is to prepare one of the more standard form, as many who have experienced such meetings will know.

Taking the contributions out of this context, one must acknowledge the quality of many of them. The range of subject-matter covered is too wide to be of universal interest for the average reader: it extends from Mason's treatment of the elastic and anelastic properties of solids, involving, for example, discussions on semi-conductor physics, to the crystal mechanics inherent in the paper on creep by Dorn and Mote, and from the applied mechanics approach to thermal fatigue, as exemplified by

the paper by Shuji Taira, to Wolfe's review of design criteria for high-temperature structures.

It is not possible to do justice to the thirteen papers in a review of this kind, but a few might be picked out for special comment. The review by Pask and Copley of the thermo-mechanical behaviour of ceramics is well done; this is, of course, one of the interesting bridge subjects at the present time in the sense, at least, that it concerns the extension of concepts, worked out originally for metallic materials, to the structure and behaviour of non-metallic crystalline materials. The Dorn and Mote review of creep mechanisms is on the lines of the kind of article one associates with *Progress in Materials Science*. Prof. Dorn's own valuable contribution to the rationalization of this somewhat over-ploughed field are well known and well respected. This survey, written in conjunction with his colleague, re-states some of the familiar premises, and one would think that in places it goes beyond the boundaries of a general review, but it is a good contribution to the review literature, and metallurgists, including those involved with teaching, will be very glad to have it. It is interesting to compare Kachanov's presentation of the variational methods of solving non-linear creep problems; the analysis is not related to any experimental results. Mullendore and Grant undertake the subject of the tertiary creep stage, covering in the main the features of boundary sliding and void formation, but at the same time stressing the point that elongation "becomes unstable in second-stage creep" and that tertiary creep need not involve non-uniform deformation and intercrystalline cracking. They also have some faith in a readier predictability of the final stages to rupture from short-term data. The subject of thermal fatigue and creep rupture, reviewed by Shuji Taira, uses as a basis the plastic strain amplitude formulation of Coffin, generalizing first to take account of temperature, and then to cover the case of a mean static stress. The theoretical results are shown to compare well with the experimental findings, but there is no consideration of its metallurgical validity.

The special conditions imposed by space technology projects are represented by papers on high-speed effects (sliding, impact) in both metals and polymers (Bowden and Brunton) and on re-entry problems (Scala). The latter paper outlines some of the materials issues, without dealing very profoundly with any one of them, directing attention to the increasing importance and difficulty of successful non-destructive assessment. The Bowden and Brunton paper draws on many of the results which Dr. Bowden's group has contributed over the years, and in the context of aerospace investigations the beautiful dissection of the problem of high-speed liquid drop impact on polymers and metals is particularly appropriate.

The difficulties inherent in problems of heat flow where phase changes occur are well brought out in the paper by Boley, who has managed to thread his way through some fairly heavy mathematics while at the same time conveying the significance of the results to the behaviour of real materials.

Those who would regard their province as being materials science and engineering will find the book worth sampling.

A. J. KENNEDY

THE GENUS SYNCHYTRIUM

Synchytrium

By Prof. John S. Karling. Pp. xviii+470. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 125*s*.

THE name of Karling and *Synchytrium* have come to be regarded as almost synonymous, and the choice of John S. Karling, Wright distinguished research professor of Purdue University, Indiana, to undertake the writing of this volume on *Synchytrium* which is dedicated to the memory of Anton De Bary and Michael Stepanovitch Woronin on the occasion of the centennial of the creation of the genus, is a happy one. Founded by De Bary and Woronin in 1863 for the two chytrid species *S. taraxaci* and *S. succisae*, the genus *Synchytrium* now includes more than 200 members; several new sub-genera have been established and almost 100 of the species have been added in the past 30 years.

Sixteen preliminary pages containing the preface, acknowledgements and a list of the herbaria consulted are followed by the introduction and Chapter 1 which provide general descriptions, illustrations of the life cycles and the types of development shown by the six sub-genera. The illustrations are excellent, and after reading this portion of the book the reader feels he has gained a good working knowledge of the genus. Having made it clear that criteria other than those based on morphological differences must be taken into account in any taxonomic investigation of the genus, the writer then proceeds in Chapters 2, 3 and 4 to deal with cytology, sexuality and host reaction respectively. The chapter on cytology is both well written and well illustrated. The considerable disagreement concerning nuclear behaviour, etc., emerges clearly; a truer picture will only result from further intensive investigation, when the employment of modern techniques has eliminated errors and misinterpretations. Sexuality is fully discussed in Chapter 3 and an investigation of host reaction, again beautifully illustrated, is provided in Chapter 4. Chapter 5, which deals with the evaluation of taxonomic criteria, is probably one of the most valuable, pointing out as it does the variability of so many characters in the various species and underlining the danger of using any but the most constant for taxonomic purposes. Indeed, in Chapter 6, which deals with systems of classification, that selected by the author is based entirely on the reproductive organs and the mechanism of reproduction, which form the most reliable guide. Chapter 7 provides full descriptions of the genus, the sub-genera and the species. It occupies 239 pages or just about half the book. The species for each sub-genus are divided very wisely into those described as fully known, those which are incompletely known and those which remain unidentified. Chapters 8–10 deal with relationships and phylogeny, geographical distribution and a host index respectively. References occupy the next 24 pages and, except for the author and subject indexes, the book concludes with a bibliography for *S. endobioticum* and wart disease of the potato which runs to 30 pages.

It seems extraordinary that only one species in this genus of obligate parasitic chytrids should have assumed real economic importance. The species is of course *S. endobioticum*, which causes wart disease of the potato. Its appearance in Europe in 1896, only 50 years after the potato famine caused by late blight (*Phytophthora infestans*), caused great concern; its ravages have been met by the use of resistant potato varieties. *S. endobioticum* is comprehensively dealt with in the text and the bibliography which appears at the end of the book is most valuable.

In his preface the author points out that the genera and species of aquatic chytrids are fairly well known, and described in a series of excellent text-books, but that these investigations do not cover the large terrestrial genera *Physoderma* and *Synchytrium*. The purpose of this book is to fill one of these gaps and to direct attention to the many problems which remain to be solved by the further intensive investigation of individual species. The author can rest assured that his purpose has been fulfilled and that his book might well serve as an example to other classical biologists who have the ability, the good fortune and the patience to pursue the investigation of an individual genus or a group of genera. Perhaps its message is of special import to the classical microbiologist, for the simpler the organism the greater the difficulty of classification—ranging from the microfungi through the bacteria to those nameless

ones—the viruses—which hover between the living and the dead. It is clear that the species concept in microbiology takes on a somewhat different meaning from that which it carries in the case of the higher organisms, and a reference to volume 6 of Rabenhorst's *Kryptogamen-Flora*, where recorded species of *Phyllostica* occupy 155 pages and those of *Phoma* 181 pages, illustrates the point. It is sometimes tempting to wonder whether, in many cases, there is any significant difference other than the host plant on which the species is recorded. It is also tempting to wonder whether a micro-organism, with its habit of physiological specialization and its aptitude for producing physiological races, behaves "as if increase of appetite had grown by what it fed on". If this book does anything further it shows the need for more taxonomy and, in particular, more experimental taxonomy, and its reading will be well worth while for all postgraduate and research classical biologists.

The volume attains the high standard of production expected from Academic Press: the text is extremely free from typographical errors and only two cases of misspelling were detected. Arthur E. Muskett

VARIABILITY OF SPONGES

A Revision of the Classification of the Calcareous Sponges

With a Catalogue of the Specimens in the British Museum (Natural History). By Dr. Maurice Burton. Pp. v + 693. (London: British Museum (Natural History), 1963.) 300*s*.

THE systematics of sponges are notoriously difficult. Breeding experiments for the present are out of the question, so that one's concept of a species must depend on the general form, histology, spicule characteristics, development, and habitat-preferences of the animals concerned. For the great majority of the species hitherto described, however, information is only available regarding the form and skeleton, both of which can show great variation. This is clear from Dr. Burton's book, which is undoubtedly a major contribution to our knowledge of the systematics of sponges.

The book is divided into four main sections. The first includes observations on the range of variation in some common littoral species. Even in the same individual the spicules may vary widely in form and size, while the canal system may assume either the syconoid, grantioid or leuconoid arrangement. Using knowledge of the variability thus gained, Burton examines the genera hitherto recognized and reduces their number from 55 to 22. He then lists the previously accepted species, giving each the equivalent specific name in his revised classification. Of the original 623 species (including 12 varieties) only 47 (48, according to Burton) remain.

Such extensive lumping will be considered by many to be unwarranted at the present state of knowledge. Can one be certain that the range of variation found for one species is equally applicable to another? Might not specimens with roughly similar spiculation and living in the same locality yet be found to differ in their development or habitat-preferences? Is it justifiable to ignore the position of the nucleus (apical or basal) in the choanocytes because there is more doubt about its taxonomic value than with the spicule characters (p. 31)? By so doing, Burton is able to lump together under *Leuconia barbata* several former species with apical nuclei and several with basal nuclei. To what extent does hybridization between species obscure the estimation of their variability? When *Sycon ciliatum*, *Leuconia fistulosa* and intermediate forms were discovered growing closely together, Burton regarded this as evidence for the variability of the former species, yet hybridization might conceivably have been involved. Only by growing regenerated portions of the same sponge in different environmental conditions can one obtain a satisfactory estimate of the possible range of variation for a given genotype.

The second section presents the systematic account of the Calcarea as understood by Burton. Apart from the great reduction in number of species, one can criticize his definition of the Homocoelidae, namely, "Calcarea having the whole endosomal cavity (or cloaca) . . . lined by collared cells". This is inexact, since choanocytes are lacking at the distal ends of the cloacal tubes.

The third and fourth sections will be of great value to future taxonomists. The latter is a catalogue of specimens and slides in the British Museum (Natural History) collection, while the former comprises brief diagnostic descriptions, often illustrated, and references for all the hitherto recognized species, grouped according to Burton's classification. Here, it would have been helpful if the author had indicated the precise source of the descriptions under each species, so that the reader could check and amplify them if necessary. Thus, under *Leucosolenia variabilis*, the spicule characters appear to have been derived at second-hand from Arndt's *Die Tierwelt der Nord-und Ostsee, Porifera* (1935), for the same mistake is found when one compares the widths of the rays of the triradiates with those given in Minchin's original description. Information provided by Minchin on the range of variation in this species has been excluded.

The bibliography is complete up to the year 1953, but suffers from one defect, in that where several publications by the same author appeared in the same year no attempt is made to distinguish between them. Also the reference to Burton (1931) (p. 5) does not appear in the list.

While Dr. Burton's simplified classification will be regarded by many as premature, there can be no doubt that he has produced a remarkable book; one which will be a starting point for future revisions of the classification for many years to come. W. Clifford Jones

AGRICULTURAL PESTS

Pests of Field Crops

By F. G. W. Jones and Margaret G. Jones. Pp. viii + 406 + 32 plates. (London: Edward Arnold (Publishers), Ltd., 1964.) 50*s*. net.

MORE than a century ago, John Curtis wrote the first comprehensive practical book on British farm pests. He dealt mainly with insects but also devoted space, proportionate to existing knowledge, on nematode, molluscan and other pests of farm land and farm stores. In *Pests of Field Crops*, Mr. and Mrs. Jones have produced a present-day 'Curtis'; while their book is intended for students and is concerned mainly with the animals which annoy the British farmer, they draw fully on examples from Europe and elsewhere to illustrate appropriate points. While emphasizing for each species the importance of field ecology and natural control, the authors give full consideration to chemicals and the overall coverage is comprehensive and well illustrated. There the similarity ends, because 'Curtis' was written at a lower level of technical sophistication when man and agriculture were accepted as part of Nature; Jones and Jones, in the second line of their first chapter, define agriculture as "interfering with nature".

So the tone of the book is set: pests are animals in the wrong place and must be eliminated, provided that man is not inconvenienced by pesticide residues in the process. With such an end in view the student must be taught the fundamentals of population dynamics and have a good grounding in ecology. By the time the reader has finished the nine pages of Chapter 1 his appetite is whetted for more information on what constitutes a pest, but instead he is given 24 pages of elementary morphology in Chapter

2. The balance is redressed to a large extent in Chapters 14 and 15, where general relationships between crops and pests are discussed, and consideration is given to problems of pest numbers and crop yield and to various aspects of natural control. Population problems are also discussed in some detail in the chapter of 52 pages on plant parasitic nematodes—the subject of the senior author.

Nearly half the book (195 pp.) is devoted to insects, which are taken in systematic order. Notes on family classification are followed by brief taxonomic descriptions of the more important species which are illustrated with line drawings (which sometimes lack precision). The descriptions lead into biological summaries and notes on crop hosts, damage, and control methods. Sometimes the biological notes are out of date: few applied entomologists to-day would accept that a wireworm population of 5–600,000 per acre does no damage to cereals, or that most crops can be grown with safety on 1 million wireworms per acre (p. 117). Pea moth is said (p. 93) to have become increasingly important in parts of eastern England, when growers generally appear to be much more concerned about crop maturation delays caused by weevil, thrips, or aphid attack than by moth damage. Generally, however, the biological notes are excellent and the authors are to be congratulated on condensing so much scattered information into concise and readable prose.

Four pages are devoted to molluscs, and the section on slugs (1·5 pp.) could with advantage be expanded in future editions, because some modern farming methods (ploughing-in long combine stubbles from successive cereal crops on heavy land, for example) appear to be encouraging slug population growth.

The 29 pages devoted to vertebrate pests form a most useful addition to the book, bringing together in one place much scattered information from journals and bulletins which students probably cannot hunt out individually.

In all, this is a remarkably good book. The authors have taken great pains to cite up-to-date literature, often papers published in the past five years or so, the latest being a report published in March 1964, two months before the book went to press. As an added precaution many of the sections into which the book is divided were checked prior to publication by established specialists, and the acknowledgements in the authors' preface include many respected names. Printing and paper are good, typographical errors minimal, and most of the plates—culled from many sources—are excellent even though they are often badly placed in relation to the text. A. H. STRICKLAND

STYLE AND COMMUNICATION

Science, Humanism and Libraries

By D. J. Foskett. Pp. ix+246. (London: Crosby, Lockwood and Son, Ltd., 1964.) 26*s*. net.

IN *Science, Humanism and Libraries* Mr. Foskett has sandwiched, between two essays based on a thesis dealing with T. H. Huxley as a writer on science, a miscellany of sixteen papers and essays delivered over the years 1951–62. They comprise such themes as special libraries, readers' needs in industrial libraries, documentation in the humanities, in the social sciences and in occupational health and safety, national lending libraries, classification and communication and reference services, comparative and faceted classification, the work of the classification research group, and a historical essay on the pioneer of documentation, Marc-Antoine Jullien. Scattered through them are quotations from the writings of T. H. Huxley, but the thread of communication, while plausible, is somewhat tenuous. Some of the essays, in fact, are rather too technical or specialized for the general reader, who may thus be deterred from pursuing a book which contains much of general interest and goes to the roots of what is involved in the present-day controversy over two—or more—cultures.

This would be unfortunate, for the papers do far more than display the range of Mr. Foskett's interests and the penetration of his thought. Even at his most technical he has shrewd, sound comments to make, though it must be admitted that here and there the essays require to be brought up to date. He pays a generous tribute, well-deserved, to the work of Dr. S. R. Ranganathan, and to the many stimulating comments which should not be overlooked by his professional colleagues.

Of the core or inner layer of the book, it could be said that it is a remarkable demonstration of the feasibility of combining in one person expertise and clarity of exposition, specialized and general knowledge. In other words, the antithesis of the two cultures is a false dichotomy, and from that point of view this part belongs to the outer layers with their dissertation on science, on humanism and libraries. It is only because a thinner sandwich might have attracted a wider circle of readers that there is reason to regret the more technical filling was not curtailed.

Mr. Foskett's study of T. H. Huxley as a writer on science convinces him that it is possible to present scientific results in good English, understandable by all, and that difficulties of communication are due ultimately, not to the material but to lack of good style on the part of the writers. Dullness, he observes, lies in the presentation of the material. A. N. Whitehead, in *The Aims of Education*, asserted that style, in its finest sense, was the last requirement of the educated mind. "The administrator with a sense of style hates waste; the engineer with a sense of style economizes his material; the artisan with a sense of style prefers good work. Style is the ultimate morality." Lewis Mumford expresses much the same idea in the sense of fitness for the purpose which pervades his *Technics and Civilization*, and George Stuart Gordon in *Anglo-American Literary Relations* asserted that "Wherever a man has fairly set down the best that he knows about the thing he knows best, and in words that tell his meaning, there, always, will be literature".

Mr. Foskett's onslaught on this imaginary gap between science and humanism is timely and finds ample support. It is refreshing to find an expert who not only quotes Quiller-Couch on writing but also refers to Pater's essay on style. Curiously enough, he does not quote the most pertinent passage in that essay, the reference to the dependence of style on self-restraint, the skilful economy of means, the choice of the unique word, phrase, sentence, paragraph, absolutely proper to the single mental presentation and vision within. Nevertheless, he reminds the scientist that false reactions in presentation and writing depend not on the qualities of the subject but on factors extrinsic to the subject, and that if the character of scientific material does not properly arouse human feelings, the writer has not presented his material efficiently.

These opening and closing essays of the book deserve to be widely read and pondered, not only in relation to the present-day debate on the two cultures, but in respect of the even wider issues of communication. Communication, he reminds us, is more than merely being told something; a successful lecturer constantly strives to bring his new ideas into relation with what the audience already knows. The primary requisite is to arouse interest, and the writer succeeds in communicating inversely with the effort the reader has to make to establish this bridge of understanding. Mr. Foskett offers no prescription for improving the situation other than his challenge to his fellow librarians to make a particular professional contribution, but what he writes is stimulating and suggestive. Neither the general reader nor the scientist need be at a loss for clues as to what steps he could himself take to remedy a situation that constitutes an indictment of our educational system as a whole. R. BRIGHTMAN

Deltaic and Shallow-Marine Deposits

Proceedings of the Sixth International Sedimentological Congress, The Netherlands and Belgium, 1963. Edited by L. M. J. U. van Straaten. (Developments in Sedimentology, Vol. 1.) Pp. xvi+464. (Amsterdam, London and New York: Elsevier Publishing Company, 1964.) 130*s*.

Deltaic and Shallow-water Littoral Marine Deposits

Edited by V. S. Yablokov and others. Pp. 263. (Moscow: Academy of Sciences, 1963.) 1r. 67k.

DELTAIC and Shallow-Marine Deposits is a compilation of 58 short papers presented to the Sixth International Sedimentological Congress held in 1963. Other than the thought-provoking presidential address by Dr. F. P. Shepard on "Criteria in Modern Sediments useful in Recognizing Ancient Sedimentary Environments", the contributions (in English, French or German) are all research reports, more or less related to the general theme of marine sedimentation under deltaic or shallow-water conditions in Phanerozoic, Recent and modern times. They describe deposits in 20 different countries and are almost as diverse in the nationalities of the authors. In connexion with the same Congress, the Commission on Sedimentary Rocks of the U.S.S.R. Academy of Sciences (Division of Geological and Geographical Sciences) has published the second-mentioned volume of articles, which begins with a useful review by Dr. G. F. Krasheninnikov on "Fossil Deltas of the U.S.S.R.". Unfortunately, only 7 of the 40 Russian contributions appear in translation in the official *Proceedings*, and the small edition (800 copies) of the Moscow publication will make it difficult to procure. However, the high price of the official record will certainly not facilitate a widespread circulation even of the papers printed in Western languages, distinguished though many of them are.

In both books the recent growth of interest in these shallow-water sediments is attributed to the belief that, since such deposits form the host-rocks for many useful minerals, a knowledge of the laws that govern the formation of the strata will be useful in interpreting the genesis of ores and in planning prospecting work. This, however, presupposes that ancient sediments have remained a closed chemical system throughout their history and that pay metals have not been introduced or redistributed by ground-waters. Perhaps the most useful outcome of the actualistic approach to sedimentology, followed by the papers in these symposia, will be a wider recognition of the nature and extent of the post-depositional chemical changes which many older sedimentary rocks have undergone; but this will not come about until more sedimentologists have entered into alliance with geochemists, the assistance of whom they seem at present inclined to eschew.

C. F. Davidson

Advances in Inorganic Chemistry and Radiochemistry

Edited by H. J. Emeléus and A. G. Sharpe. Vol. 5. Pp. ix+429. (London and New York: Academic Press Inc., Ltd., 1963.) 103*s*. 6*d*.

EACH of the volumes in this series has provided articles of general interest to all inorganic chemists—articles which have been, and are, of very great use to research workers in the fields covered. The subjects dealt with in the present volume again range widely over inorganic chemistry and are of general, and particular, interest. R. S. Nyholm and M. L. Tobe discuss the stabilization of oxidation states of the transition metals. The treatment is simple and the chapter could well be required reading for any honours course in chemistry. Another general review is "The Structure and Reactivity of Organophosphorus Compounds" by R. F. Hudson, an article which considers the reactivity of these derivatives in terms of the properties of the phosphorus atom. Of a far more specific nature are the exhaustive reviews on the "Oxides and Oxyfluorides of the Halogens" by M. Schmeisser and K. Brändle, on "The Borazines" by E. K. Mellon, jun., and J. J. Lagowski, and on "Decaborane-14 and its Derivatives" by M. F. Hawthorne. The last-named is a particularly clear and lucid discussion of a subject which is undergoing rapid development at the moment. N. N. Greenwood reviews "The Chemistry of Gallium" with specific reference to the developments made in the chemistry of this element during the past ten years, while O. Glemser and H. G. Wendlandt write on "Gaseous Hydroxides", giving particular emphasis to the transition metal hydroxides. The only article on radiochemistry is "Chemical Effects of Nuclear Activation in Gases and Liquids" by I. G. Cambell. It does not fit in too well with the other articles in this book, as most of the molecules considered are organic in nature.

Master Equations and Tables for Symmetrical Component Fault Studies

By S. Austen Stigant. Pp. x+78. (London: Macdonald and Co. (Publishers), Ltd., 1964.) 25*s*. net.

THERE are many similarities between the various conditions of unbalance which can occur in three phase systems, and Mr. Stigant demonstrates the manipulation of the symmetrical component equations in each case to reduce as many problems as possible to basic equations which can then be applied to a given case, by means of tables, in a routine manner. It is of interest to examine this book with regard to its claim "to be of considerable value to H.N.C. students and teachers of electrical system theory, and to system engineers concerned with fault analysis".

There is much more to the application of symmetrical component theory than the manipulation of equations, as the author himself states, and the electrical engineering Higher National Certificate student would do well to achieve a full understanding of the method, from such sources as the adequate list of references given, before turning to the material of this book. Teachers, of course, will be interested in the approach, but practising systems engineers with problems of such complexity that the tables of equations are needed should to-day have access to, or be thinking of, digital computer programmes in which such routine manipulation is included. Simple connexion matrix techniques are described and provide a link with the author's other well-known books, but the possibility of computer application is not introduced. This is disappointing, because I feel that the book could have been valuable in introducing Higher National Certificate students, or the engineer as yet unaware of computers, to the means by which the drudgery of routine calculation is being eliminated in this field as in others, leaving the modern engineer more free for creative effort.

M. N. John

Personnel and Industrial Psychology

By Prof. Edwin E. Ghiselli and Prof. Clarence W. Brown. Second edition. (McGraw-Hill Series in Psychology.) Pp. ix+492. 1955. 45*s*.

Heat and Thermodynamics

An Intermediate Textbook for Students of Physics, Chemistry, and Engineering. By Prof. Mark W. Zemansky. Fourth edition. Pp. xi+484. 1957. 36*s*. (New York and London: McGraw-Hill Book Company, Inc.; Tokyo: Kogakusha Company, Ltd.) International Student Edition.

THE paper-back text-book resolves, to a large extent, the dilemma of the bound science treatise. The binding of a book may cost more than the printing of it, and science books become out of date so quickly. For decades, the French have been aware of this, and book production has been separate from binding. It is not surprising that more publishers are producing solid, academic works in paper-back form. The latest examples are the McGraw-Hill International Student Editions, originally American, and published in England in Maidenhead. They are warmly

welcomed. The saving of cost, by having a paper-back instead of a more substantial binding, is from 30 to 60 per cent. The range of subjects is large and includes sociology, mathematics, mechanics, geography, psychology, medicine, engineering, physics, chemistry, biology and communication theory.

The greater availability of so many text-books and standard works raises an important question. What *is* a student's text-book? Particularly in view of the great extension of university and technical education, with its concomitant increase of examinations, considerations of the nature of the text-book and the purpose and the technique of examination are important and overdue. Some text-books are treatises with notes, others just 'boiled down' treatises, some are mélanges of other treatises and text-books. There is a great spectrum of possibilities in science books for students, from treatises and original papers which make no concessions to the reader, to the programmed or self-help text-book in which every paragraph has been evolved according to the most recent pedagogical and psychological principles. Again, the relations of the text-book to the teacher's work, the student's writing, the recent research, the examination syllabus if any, the maturation level and intelligence of the student are all important. Here is a field which is in urgent need of a thorough investigation.

W. L. SUMNER

Short Guide to Geo-Botanical Surveying

By S. V. Viktorov, Ye. A. Vostokova and D. D. Vyshivkin. Translated by J. M. MacLennan. (International Series of Monographs on Pure and Applied Biology. Division: Botany, Vol. 8.) Pp. xi+158. (Oxford, London, New York and Paris: Pergamon Press, 1964.) 63*s*.

IN any country with large sparsely inhabited regions vegetation surveys are of great importance in assessing natural resources.

Short Guide to Geo-Botanical Surveying reviews the procedures that have been employed in Russia. It is concerned chiefly with the planning of surveys, and discusses the suitability of various methods of ground traversing and aerial interpretation, the setting out of the sample traverses or plots, the data that should be recorded, and how these may be represented cartographically. The practical applications of such surveys are emphasized in separate chapters dealing with forests, peat bogs and grazing land, and with the use of vegetation as an indicator of soil conditions or mineral deposits.

The procedures advocated are mainly of an empirical nature found to be satisfactory by experience, and there is no attempt to estimate the accuracy of different sampling methods. Indeed, with exploratory surveys on a regional scale the choice of method is often dictated more by the nature of the country and the resources available than by academic considerations of sampling density. It is essentially a manual on the organization of survey networks, and strictly ecological topics such as the assessment of botanical composition and the recognition of plant communities are scarcely touched upon.

W. D. CLAYTON

Symposium on Instrumentation for the Detection and Determination of Pesticides and their Residues in Foods

Los Angeles Meetings of the American Chemical Society, April 1963. (Residue Reviews, Vol. 5.) Pp. viii+176. (Berlin, Göttingen, Heidelberg: Springer-Verlag, 1964.) D.M. 26.

THE declared object of Residue Reviews is to make available on an international basis concise, critical reviews of advances in the field of residues in foods, whether in methods for measuring residues, in the understanding of their significance when measured or in methods of controlling their incidence (by legislation or otherwise). This volume differs from the five others so far published in the series in that it is the only one to result from a symposium—organized for the American Chemical Society by the series editor, Dr. F. A. Gunther. It shares in common with the other volumes the fact that for the most part the residues considered are those of pesticides.

With the exception of Dr. H. Frehse, who contributes the opening chapter, all the authors are American. Dr. Frehse considers the problem of residue analysis and food control. He compares the classical, general 'wet' methods of residue analysis (for example, for organo-phosphorus or for chlorinated pesticides) with esterase and bioassay techniques and with the more modern physicochemical methods such as chromatography. And he contrasts the position of the commercial analyst, normally concerned with field trial work in which the identity of the residue is known, with that of the official analyst to whom the field history of the crop or food will probably be quite unknown. There is useful comment on the expression of results in relation to the precision and sensitivity of the analytical method used. Nine of the remaining eleven chapters of the volume are devoted to detailed practical aspects of pesticide residue analysis, ranging from detectors for gas chromatographic work to neutron activation analysis and the automation of 'wet' methods. R. C. Blinn deals with the general subject of residue analysis using infra-red and ultra-violet spectrophotometry, and in the remaining chapter specific consideration is given to polarographic and (despite the title of the chapter) spectrophotometric and gas chromatographic methods for the determination of additives in animal feeding-stuffs.

The volume is primarily of direct interest to practising pesticide-residue analysts: it is at the same time of general interest to those otherwise concerned with the control of residues, and it gives some insight into the complex and varied methods to which residue analysts now resort.

H. EGAN

The Practical Home Gardener

A Guide to the Cultivation of Plants in Australia with special details for the Drier Regions. By T. R. N. Lothian. Second edition, revised. Pp. xix+390+32 plates. (Melbourne: Lothian Publishing Co. Pty., Ltd., 1963.) (A) 97*s*. 6*d*.

IN this recent addition to Australian gardening literature, Mr. Lothian ranges widely, from structural botany to the organization of flower shows. Though writing more particularly for suburban gardeners, he adds useful advice here and there for those struggling with the problems of horticulture in remoter areas.

From his experience of gardening in the extremes of a Mediterranean climate, Mr. Lothian is able to suggest many useful and interesting ornamental trees and shrubs worth trying in other parts of Australia where long dry periods occur, and to this topic he devotes his two longest chapters. Vegetable and fruit growing also receive a fair share of space, but the treatment of other subjects is more sketchy and the touch less sure. An extreme case is the chapter on soils which amounts to only two and a half pages, nearly all of which might have been written for gardeners in Europe. A fuller account of so large a subject, with more reference to Australian conditions, would surely have been useful here.

Throughout the book, much of the information is given in tabular form, whereby space is saved and reference facilitated. The illustrations include a coloured frontispiece and more than sixty black-and-white plates, some rather indifferent in quality. There is also a number of line drawings which will help the reader, though a few of these would have been better if somewhat larger and less confused with shading. Not all spelling mistakes have been detected. Among those which remain are the words *calciphobe* and *calcicole* whose meanings are also transposed.

J. SOUSTER

RADIO ECHO SOUNDING OF POLAR ICE SHEETS

By J. T. BAILEY, Dr. S. EVANS and Dr. G. de Q. ROBIN
Scott Polar Research Institute, Cambridge

FOLLOWING reports by Waite and Schmidt[1] that radio altimeters operating at a frequency of 440 Mc/s could be used to obtain echoes through polar ice sheets up to 300 m thick, equipment was developed in the Scott Polar Research Institute for the specific purpose of sounding cold polar ice sheets. In particular, it was decided that for maximum penetration of ice it was desirable to use the lowest practicable radio frequency. The first set to be built[2] operated at 35 Mc/s and a report on the use of this equipment during 1963 on the Brunt Ice Shelf near the Halley Bay station of the British Antarctic Survey has been prepared by M. E. R. Walford (*Nature*, 204, 317; 1964). Short trials of a second set on the ice sheet of north-west Greenland are summarized in a note by Evans[3]. As part of the same trials, A. H. Waite obtained further measurements with equipment operating on 440 Mc/s and on 110 Mc/s.

An invitation to participate in more extensive trials in the same area during June–August 1964, from the Commanding Officer of the U.S. Army Electronics Research and Development Laboratories, led to further development of equipment during 1963/64. Field operations were supported by the U.S. Army Research Support Group and the general programme of traverse investigations was directed by Dr. J. Rinker of the U.S. Army Cold Regions Research and Engineering Laboratories. As a result of this generous support trials of radar sounding equipment developed at Scott Polar Research Institute and at the U.S. Army Electronics Research and Development Laboratories were made during a journey of 130 miles from Camp *Tuto* (76° 25′ N., 68° 28′ W., elevation 480 m) to Camp *Century* (77° 11′ N., 61° 09′ W., elevation 1,930 m), then to distances 40 miles south and 50 miles north-west of *Century*, and back to *Tuto*. Reports on the performance of the U.S. Army Electronics Research and Development Laboratories equipment will appear separately, but the results were in close agreement with those obtained with the Scott Polar Research Institute equipment and both agreed with preliminary interpretations of results from seismic shooting.

The chief parameters of the Scott Polar Research Institute equipment were similar to those given by Evans[2]: radio frequency 35 Mc/s and energy pass band 14 Mc/s. The main developments were that receiver and control circuits were transistorized and a continuously moving photographic film was used to record echoes displayed on an intensity modulated cathode ray tube. Examples of the records are shown in Fig. 1.

A continuous profile of the form of the bottom surface of the ice was obtained over 97 per cent of the route travelled. The ability to obtain a continuous record will be of great help towards our understanding of the factors governing the surface form and flow of the ice sheet, since our knowledge has been limited hitherto by the difficulty of obtaining a general picture of bottom relief from the spot soundings resulting from seismic shooting or from the areal average figure presented by gravity measurements. The limitations of radar sounding arise mainly from the loss of signal strength by dielectric absorption of the radio wave in the ice. A review paper by Evans (in the press) shows that these losses decrease considerably as the temperature of the ice is decreased. The method is likely to penetrate the full depth of ice sheets over extensive areas of Greenland and Antarctica. During the recent trials, echoes were obtained with the Scott Polar Research Institute equipment through 1,400 m of ice, the maximum thickness of ice which was encountered. The echo strength was then up to 30 dB above receiver noise-level and the mean temperature of the upper part of the ice sheet was −24° C. However, diffi-

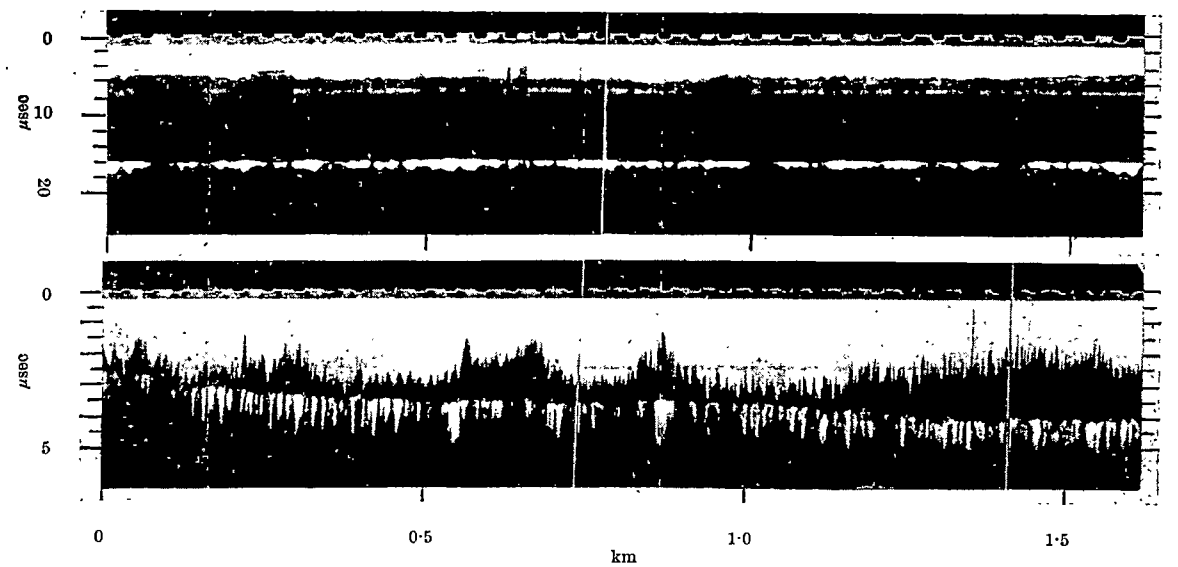

Fig. 1. Continuous recordings of radio echo soundings through a polar ice sheet. The horizontal scale (km) represents distance travelled along the snow surface. The vertical scale (μsec) has an arbitrary zero; the transmitter pulse occurs at the top edge of the broad white band caused by clutter echoes. The upper record shows an echo from an almost horizontal ice rock interface. The echo time delay is 15 μsec corresponding to an ice depth of approximately 1,300 m. Note the weak but continuous echo from a discontinuity in snow structure at a depth of approximately 500 m. The lower record, using a more open time (depth) scale, shows reflexions from an irregular and much shallower bottom surface. Note the variation in echo strength with horizontal position and the occurrence of echoes with longer time delays than that from the normal point

culty was experienced in following a bottom echo through an ice thickness of 500 m when the ice temperature was close to 0° C.

While moving over the ice sheet, the echo from the bottom of the ice increases or decreases in strength as one moves through distances of the order of the radio wavelength. In addition, aerials with a broad polar diagram were used so that strong echoes could be received from angles up to 35° from the vertical. If the bottom surface, though rough, has a slope less than 35° to the horizontal, the minimum time delay echo will arise from a direction normal to the average surface, and echoes at longer time delays (Fig. 1) are supposed to arise from facets or irregularities in the bottom surface at some distance to either side of the normal point. Occasionally the 'normal' echo may be missing, and it is evident that continuous recording is essential to avoid the misinterpretation which would arise if only spot soundings were made.

Within the limitations of many practical compromises the apparatus is given the greatest attainable sensitivity. Since the signal is attenuated as it travels through the ice, the sensitivity required to observe reflexions from the bedrock is much greater than is necessary to observe strong reflectors at short range. For example, a metallic object with effective echoing area 10^{-2} m^2 would be detectable in an otherwise isotropic medium at 250 m depth and a smooth extended surface at the same depth should be detectable if it reflected only 10^{-7} of the incident power. Thus we expect that compacted annual layering of the snow is responsible for the continuous echoes observed from ranges up to a few hundred metres. A change in average specific gravity of the snow from 0·90 to 0·905 taking place in a layer less than 1 m thick will have a power reflexion coefficient of 10^{-6} and should just be detectable down to depths of 500 m. The short range echoes, analogous to 'clutter' from the sea surface in conventional radars, appear as a continuous return signal on the intensity-modulated display. Discrete echoes were observed from layers in the ice down to depths of 500 m over about half the total distance travelled; examples can be clearly seen in Fig. 1. The investigation being undertaken at the U.S. Army Cold Regions Research and Engineering Laboratories of ice samples which have been obtained by thermal drill coring from these depths at Camp *Century* may identify the different physical properties of various layers of the ice sheet which give rise to echoes. We expect that such differences are related to climatic changes during past centuries.

The comparative trials of equipment developed at the U.S. Army Electronics Research and Development Laboratories and at the Scott Polar Research Institute were of mutual benefit in many ways. Special acknowledgement is given here to the advantages of using a balanced-feed aerial supported at least 3 m above the snow surface (Electronics Research and Development Laboratories system) rather than the mechanically simpler system of dragging an unbalanced aerial wire over the snow behind the vehicle (Scott Polar Research Institute system). The efficiency of the Scott Polar Research Institute equipment was increased by adopting the Electronics Research and Development Laboratories aerial which was kindly loaned for this purpose.

The purpose of this article is to direct attention to the potentialities of the new technique. A detailed analysis of the glaciological results obtained in north-west Greenland and a description of the equipment will appear in later publications when comparative figures from seismic shooting and gravimetric measurements are also available. In particular, one method for the determination of the velocity of radio waves in snow of different densities rests on a knowledge of snow depths derived from seismic measurements in areas where the radar showed the bottom surface to be smooth and flat. An independent method, using transmitting and receiving aerials spaced some distance apart on the snow surface, was also used, and it is not yet certain which method will yield the more accurate result.

In addition to the acknowledgements in the second paragraph, we thank the Committee of the R. W. Paul Instrument Fund for the provision of grants to cover the entire cost of the development work at the Scott Polar Research Institute. Special thanks are due to Mr. A. H. Waite of the U.S. Army Electronics Research and Development Laboratories, and Dr. J. Rinker of the U.S. Army Cold Regions Research and Engineering Laboratories, for their help during field operations.

WHY SHOULD WE STUDY HIGH-ENERGY NUCLEAR PHYSICS?*

By Prof. C. F. POWELL, F.R.S.
Department of Physics, University of Bristol

HIGH-ENERGY nuclear physics raises wide issues of public policy; such questions, for example, as: "What proportion of an economically advanced nation's resources should be devoted to fundamental science?" and, "By what principles should the degree of support for any particular science, in comparison with others, be determined?"

History of the Subject

Throughout human civilization, since the time of classical antiquity, men have speculated about the constitution of all the manifold variety of things which surround us. Until the beginning of the nineteenth century and the development of chemistry, knowledge was fragmentary and even the reality of the existence of the chemical atoms was uncertain. Only with the great advances at the end of the century, especially the discovery of radioactivity and the demonstration of effects due to individual atoms was the question put beyond reasonable doubt.

In the years which followed, the nuclear structure of the atoms was established through the work of Rutherford and Bohr, and the Pauli exclusion principle allowed an explanation of the regularities shown in the Mendeleev Periodic Table of the elements. With the discovery of the neutron it appeared that the model of the constitution of the atomic nuclei as assemblies of neutrons and protons had brought us near to the goal of a description of matter in terms of a very limited number of elementary constituents; nucleons, electrons and the quanta of radiation. Although such a description, guided by the principles of quantum mechanics, provided a sound basis for a detailed understanding of atomic physics, of the principal features of the solid state of matter, and of chemistry, the idea that we were approaching an end to the possibility of a deeper penetration into Nature proved to be illusory. The apparent simplicity was a consequence of our restricted resources for experiment; especially the limited energies of the bombarding α-particles, available for

* Substance of a contribution on "High Energy Particle Physics" delivered before the British Association for the Advancement of Science, Southampton, on September 1.

probing into matter, and the corresponding limits on the closest distance of approach between interacting particles which we could then achieve.

Later in the 1930's, with increasing sophistication in the methods of investigating cosmic radiation, a new sub-nuclear world began to be discovered, and the foundations were laid for the particle-physics of our time. Beginning with the discovery of the muon or heavy electron by Anderson in 1937, and especially after 1945, a large number of entities, the mesons and hyperons were found. They were created as a result of collisions with atomic nuclei of the very energetic protons which, at the time, could only be found in cosmic radiation. All the new particles were very ephemeral, mostly with average life-times between 10^{-6} and 10^{-10} sec, and the detailed examination of their properties could not be carried far in experiments with cosmic radiation because of the very weak flux of bombarding particles which it provides. It was therefore necessary to build large particle accelerators based on new principles so that intense pencil beams, homogeneous in energy, could be generated artificially. It was found essential to provide not only beams of protons and electrons which could be accelerated directly, but also secondary beams of mesons and other particles generated through the impact of the primary protons with suitable targets.

Promise of the Subject

During the past ten years the study of sub-nuclear particles has been rapidly advanced through the work with the great accelerators. The power of experiment has also been greatly increased through the development of powerful new methods of observation, such as the bubble-chambers and the spark-chambers, together with sophisticated computing methods for analysing the significant events which they record in large numbers. Both from the point of view of precision of measurement, and of the statistical weight of the experimental material on rare events which we can accumulate and analyse, our resources have been radically transformed.

As a result of these innovations, a new world of phenomena has again been revealed. They have allowed the existence of an entirely new class of particles or 'resonances' to be established with mean life-times which may be as small as 10^{-22} sec. The immense richness of the recent discoveries, the accelerating *tempo* of discovery, may be seen from the fact that the number of known particles now exceeds one hundred. They have consequences of fundamental importance.

In the first place we begin to believe that the very notion of the world as built up of elementary particles in the Greek sense of 'atom', 'that which cannot be cut', is illusory. All particles including the proton have a structure which we are elucidating. Particles of all types can be created in sufficiently energetic collisions between other particles, and they can be annihilated into other forms of matter and energy when they encounter their own anti-particles. Any particle is not to be conceived as a permanent structure like the Greek atom, but as continually transforming, for brief instants, into other forms, and then rapidly resuming its identity. Most of our familiar world is made up of nucleons, electrons and the quanta of radiation only because they are the most stable of the great family of particles, not because they are the more fundamental, so that at our familiar temperatures it is exceedingly improbable that others will secure even the temporary independent existence which their very short life-times impose. The very notion of 'elementary particle' in the sense in which it has been used hitherto has been undermined.

Secondly, in the description of the behaviour of particles as shown by their interactions with one another, we have been forced to extend widely the conservation laws familiar to us in classical physics. In order to describe the complexities of the behaviour of the particles in their interactions with one another, we are forced to acknowledge that they have attributes for which there are no parallels in classical physics. We ascribe to them new quantum numbers such as those of isotopic spin and strangeness, which are conserved in the interactions between particles, like mass-energy or electric charge.

Elementary particle physics is thus pursuing its familiar role of penetrating ever more deeply into the material universe so that we are forced to introduce basically new concepts for the description of a radically new experience. "Experimental science", said Clerk-Maxwell a hundred years ago, "is continually revealing to us new features of natural processes, and we are thus compelled to search for new forms of thought appropriate for their description."

Thirdly, during the past year, a very important step has been taken, in the recognition of a remarkable degree of order among the particles. Until quite recently the precise masses, spins, life-times and other parameters of the particles appeared as a body of empirical fact and very few significant regularities had been distinguished. We believed that there must be an underlying order which remained to be discovered, but we could not be certain of it. Now, however, it has been shown that the particles can be arranged in well-defined groups, and the validity of the new groupings has been demonstrated by the fact that the existence of missing members and their properties have been predicted and afterwards confirmed. A celebrated example is the discovery of the Ω^- particle, the existence of which was required if the arrangements of some established particles in the Lie algebraic group SU_3 of ten was to be valid, and of which the mass was correctly predicted to 1 part in 1,000.

The analogy of these advances to the recognition of the Mendeleev Periodic Table of the chemical elements seems very close. It is a recognition of regularities which guarantee the existence of an underlying order the fundamental basis of which we may hope to discover. It is not yet the equivalent of the discovery of a new quantum mechanics or of a Pauli exclusion principle; but it gives the assurance that we may, perhaps quite soon, make fundamental discoveries of not less significance.

Parallel with the work on new particles or resonances, great advances have been made in our knowledge of the weak interactions between electrons, muons and neutrinos and other particles. We now believe that there are four fundamental interactions in Nature; the gravitational and electro-magnetic forces long known to us, the very strong forces which operate between nucleons, mesons and hyperons, and the weak forces which are responsible for such phenomena as the β-decay of the neutron and of the muon. It is a recent discovery that all the phenomena involving the weak interactions are governed by the same strength of the coupling constant between them. We can attribute to the particles a weak 'charge' analogous to electric charge which more than a hundred years ago was found to be common to all electrical phenomena; and, just as in the case of the electro-magnetic field we can describe the interaction between electrically charged particles in terms of their mutual emission and exchange of electro-magnetic quanta, and the strong forces between nucleons, mesons and hyperons as due to the exchange of 'heavy quanta', of mesons, so the weak forces may be mediated by other 'field quanta' of which the existence remains to be established.

Technical Needs for the Future

The problems already outlined here are of profound importance for our deeper understanding of the material universe. All our experience of the development of science suggests that there is indeed an order in Nature which we can discover, and that we may hope to resolve our present problems. Such an attitude is very deep in our traditions. A confidence of order in Nature, of the

existence of laws of Nature which men can aspire to elucidate, was an essential condition for the emergence of modern science in Western Europe, rather than in another civilization, such as the Chinese, of which the thought was in some ways more sophisticated, but in which Nature tended to be regarded as inscrutable.

Particle physics is then full of life and vitality and will continue to attract a large fraction of the most gifted of the youth of the world in the economically developed countries who devote themselves to science. It seems probable, however, that the solution of present problems will again require a considerable increase in our technical resources. Thus the 'field quanta' of the weak interactions, if indeed they exist, are of such a nature that experiments with beams of neutrinos much more energetic than those we can generate with our present machines will be necessary for their discovery.

It is for the attack on these problems that we need the great new machines, the storage rings, and the 300-GeV proton accelerator. They and their associated equipment of bubble-chambers, spark-chambers and computers will be very expensive as judged against the scale of expenditure on fundamental science to which we have been accustomed. Thus it is estimated that the 300-GeV machine will take about eight years to build and will cost about £120 million. If constructed in Europe it would clearly need to be supported by a consortium of European states similar to that established at CERN. By way of contrast I would like to direct attention to the *Cambridge Reporter* for November 18, 1929, which gives the expenditure of the Cavendish Laboratory for that year. It is unnecessary to emphasize the eminence of the names of those whose modest salaries are there given, or the fact that this was the period when the experimental and intellectual resources for the great discoveries of the early 1930's were being assembled: of the neutron, the disintegration of the light elements by artificially accelerated particles, and the production of electrons and their anti-particles, the positrons, by γ-rays.

The foregoing comparison of the scale of expenditure in a basic branch of physics for two periods separated in time by less than half a century emphasizes the headlong advance of science and the radically new problems which it brings in its train. The growth of science, the infusion of science into every aspect of our culture, corresponds roughly to a doubling of the content of scientific knowledge every twelve years; in a wide range of disciplines the cost has quadrupled, sometimes more, in the same period. Should we continue to support particle physics in the U.K. and in Europe at the level of expenditure with which we are now faced? What can we expect to gain from it? What shall we lose if we withdraw? By what principles should we be guided in deciding on the appropriate level of expenditure on fundamental science?

Significance of Particle Physics

In approaching these problems we must acknowledge that the share of our resources asked for by science, including fundamental science, is increasing and that it is a process which cannot continue indefinitely. But it could go on for some time at its present rate without making any very great inroads into the economy. Thus, in economically advanced countries, 2–3 per cent of the gross national product now goes into all forms of research and development, and about 2 parts in 1,000 on fundamental science, as compared with 7 per cent on armaments. Such a proportion should not, I suppose, be regarded as unduly favourable to fundamental research in a period of human history in which the development of science is the dominant feature of the times. But why 2 parts in 1,000 towards all fundamental science? Why not ten times more, or ten times less, as the appropriate proportion?

But even 2 parts in 1,000 of our resources is a substantial sum. Pure nuclear and particle physics asks for about a sixth part of it, and other demands on the public purse are pressing. Why should we allocate a considerable proportion of our scientific resources and man-power to particle physics? Although the subject is of immense promise and vitality, we cannot assert precisely how useful it will be in its influence on other sciences and on practice. In the same speech from that I have already quoted Clerk-Maxwell remarked: "For us who breathe only the spirit of our own age, and who know only the characteristics of contemporary thought, it is as impossible to anticipate the general tone of the science of the future as to predict the particular discoveries it will make". All that we can say is that always in the past great advances in natural philosophy have in the long term led to radical changes in all our thinking and eventually, through their influence on the resources and morale of science, on all our practice.

The overall return from investments in fundamental science is difficult to estimate precisely, but it is certainly very high. Thus it has recently been remarked that the total resources spent on fundamental research throughout the whole of history is approximately equivalent to the amount by which this year's total production is expected to exceed that of last. But in different sectors the period from discovery to fruition differs widely. The eventual profitability of particularly penetrating and significant branches of science, such as particle physics or the elucidation of the genetic code in biophysics, is bound to be of a different order of magnitude from that given by less widely ranging investigations, and to take longer to mature.

It is very important not to see the problem too narrowly or to make a judgement on the value of a branch of science solely on the basis of immediate material benefits. The lady in the old story of Benjamin Franklin was right to ask about the use of his new discovery and he was right to emphasize the time-scale to maturity. The discovery of the universal law of gravitation, or of the origin of species, had little direct influence on economic affairs, but their impact on the standing of science and its development was immense. Or again, the development of quantum mechanics appeared as a remote and abstract advance when it first appeared, but in addition to its great importance for physics, it laid the foundations for theoretical chemistry. It was, therefore, an indispensable element in the chain of developments which contributed to the advances in molecular biology. Its ramifications are manifold and priceless.

It is a reasonable speculation that the new advances which now seem to be coming within our grasp will not be less significant and productive in the long term. They may not contribute to the advancement of chemistry, because the methods and theory created by past physics may provide all that is there needed. But they may instead be an essential element in bringing into being whole new fields of human practice, of which at the moment we have no inkling. Nobody in the eighteenth century had any intimation of an electrical industry; or in the nineteenth, of the atomic energy industry; and certainly there will be fields of practice in the twenty-first century of which we in the twentieth will know and anticipate nothing, but the foundations for which will be laid by the pure science of our own times.

We have, indeed, in the past year, had a clear indication that particle physics, in addition to its intrinsic interest, will also be of great importance for another vital branch of science, cosmology. Among some of the radio sources, there are recently discovered visible objects, called quasi-stellars, with a brightness about 10^{12} times that of the Sun, and in which the energy-source is approximately equivalent to the rest-mass of a million suns. Among them are the most remote objects in the universe hitherto identified, and their velocity of recession is sometimes more than half the velocity of light. Their rate of energy generation is so prodigious that it cannot be due to the kind of nuclear processes which provide the energy liberation in ordinary stellar evolution. It appears that for an

understanding of these objects we shall need all the resources of general relativity and of the processes we encounter in particle physics at the highest energy. The complex interaction of different sciences, their mutual influence and support, is well illustrated by this example. Modern particle physics arose out of the study of cosmic radiation, and now the application of our advancing knowledge of particle physics to these new quasi-stellar objects promises to provide a solution for the old problem of the origin of cosmic protons of the highest energy.

It therefore appears that for an understanding of the greatest energy-sources known to us in the universe, two branches of natural philosophy which are commonly regarded as among those most remote from practical affairs are indispensable. In the development of science similar situations have occurred again and again; yet there is an innate intellectual conservatism in us which makes us slow to see that the explosive developments in science through which we have lived are likely to continue, so that, in the absence of a great human catastrophe, the advance of science, the progress of discovery and of technical innovation, knows no limits, and we fail to draw the appropriate conclusions on major problems of policy.

Consequences of Withdrawing Support from the Subject

But why should we continue to support elementary particle physics here and now when the expenses are becoming so heavy and other demands on the public purse are so pressing ? Why should we not leave this field to other countries and hope to share the fruits of their researches when they mature ? It is a question which must be faced; and it should be convincingly answered if we are to proceed.

The tone, the morale, of a laboratory, of a nation, even of a civilization, is a very delicate and impalpable quality, yet of immense importance for the whole organism. The transition from high achievement to decadence has often in the past seemed to rest on a razor's edge. There is a sudden loss of confidence; it is as if the well-springs of human creative power have suddenly been dammed-up, frustrated; and this is followed by a rapid decline.

Ours is an advancing scientific culture, and if in Great Britain and in Europe we are to make an important contribution to it, we must continue to engage in the most advanced science and technique. We must encourage the most gifted of our youth to apply themselves to the most difficult, significant and demanding of the sciences, and at the present time that must include the physics of 'elementary' particles. In the long run it is most painful, and very expensive, to have only a derivative culture and not one's own, with all that that implies in independence in thought, self-confidence and technical mastery.

It is not easy to distinguish all the factors which contribute to morale, but I suppose that it is important for the whole of our educational system that the tradition of penetrating independent enquiry should be kept vigorously alive among us. This is surely especially so in our times when science is beginning to infuse every aspect of education, and the characteristic feature of science is change and development. The continuing theme in human history is the great battle to comprehend better the world around us, and to improve practice in the interests of every aspect of human advancement. People, including children, respect those who are successfully exerting themselves, at all kinds of levels, in this struggle. Immediately we cease to participate, our teaching tends to become stereotyped and pedantic; and in our universities that means that we must continually be involved in significant and essential researches.

So it is most important that we should continue to promote elementary particle physics, in Great Britain and in Europe, effectively. The programme you are to hear about is an important element in providing the necessary support. We all understand that it must be considered taking into account the legitimate claims of other sciences and other public demands on man-power and treasure. We should all be deeply concerned to see a balanced development. Gifted people are always in demand, and they are needed in many fields of technology as well as in fundamental science. But it may be remarked that the great attraction which elementary particle physics has for many of the most able young minds is not due to an arbitrary fashion. They are drawn to the frontiers of knowledge where the intellectual challenge is greatest. On such minds the subject exerts such a fascination that they will not easily be deflected but will go where it is actively pursued, wherever that may be. But if the subject loses its significance they will quickly drift away to other fields.

Particle physics at the present time is a large-scale operation involving thousands of people in the great national and international laboratories, but the number of key people is rather few and they do not seem to emerge in direct proportion to the increasing number of students we educate. It has been remarked that if, in particle physics, we lost a dozen of our best young physicists from Europe, our future contribution to the subject would be gravely prejudiced. A large number of competent scientists would be left with an indifferent leadership, and good generals make a great difference to the fate of armies. We are producing an encouraging number of gifted young physicists in Europe because we have a great tradition in the subject and have given it adequate support since the War, and we must not lose the position we have built up.

What should we do ?

In the future, science may perhaps be organized, not on a regional or continental, but on a world scale. It may become the principal creative activity of mankind utilizing a major part of our growing total resources. We may then be able to plan the general advance of the whole world scientific and technical front in a balanced way on the basis of the internal scientific needs of the different disciplines, with a rational distribution of the total effort between countries or continents, and without first considering their economic costs and returns. But we are clearly far from that situation to-day, and we in the United Kingdom and in Europe must look to our own culture and our own future.

I began by mentioning the present levels of expenditure on all fundamental research, and emphasized that this figure does not result from any clearly formulated policy as to what is the proper proportion to allocate for science in a modern state. So I believe it would be timely for governments and scientists to begin a well-informed enquiry into such problems as those which I posed at the beginning of my remarks. There would be some advantages if the enquiry could, in some measure, be international, for while the situation of each country has unique features and its own special problems, there is much experience which we share and we are in need, in the first place, of principles in the light of which to formulate policies.

In view of the foregoing considerations, I believe that the following propositions which bear on elementary particle physics should receive consideration as part of a wider enquiry:

(1) The present expenditure on fundamental science, about 3 parts in 1,000 of the gross national product, should not be regarded as an upper limit to what is desirable. It would still be reasonable to increase expenditure if the returns were reduced to less than half their estimated present value.

(2) The expenditure on fundamental research should be limited only by the availability of people enthusiastic and competent to do the work and able to justify to a scientifically informed council the promise, feasibility

and scientific significance of their programme. I believe that in the United Kingdom such a principle would not immediately involve us in a drastic increase in research expenditure. There are indications in the United States, whose enterprise and flexibility in the sciences we so much admire, that that limitation may perhaps be approaching. But in the United Kingdom, as in the other States of Europe represented at CERN, it is some way off; we have hidden reserves, a wealth of talent which still waits to be developed. The adoption of such a principle would eliminate any tendency towards a situation in which scientists in different disciplines are forced into a kind of fratricidal competition for limited resources, greatly to the detriment of the body of science.

When a subject or a research programme has become unfruitful, support should be withdrawn in good time, for there is nothing so demoralizing as incompetent research.

(3) While wider forms of international collaboration and exchange should be encouraged, there are good reasons for maintaining, on a world scale, a few main centres of investigation in particle physics at the present time so that there may be variety in the approach and in the ancillary apparatus, and the dangers of a mono-culture may be avoided.

(4) In view of the importance of the subject, we in the United Kingdom and in Europe should continue to give adequate support for particle physics in the high-energy region. It is an essential sector in the front line of advancing science, and is needed not only for its own contribution but also for its influence on neighbouring sciences including cosmology, meteorology, magneto meteorology and space. This will involve us both in improving the technical equipment in the United Kingdom and at CERN, and also in building a laboratory and its accelerator in the 300-GeV region. For such a programme, the time-scale is of great importance. It should clearly not be so fast that the technical and scientific problems involved are insufficiently considered so that we become involved in wasteful expenditure. But there are substantial financial reliefs to be gained from a slower *tempo*, and we shall almost inevitably proceed at a rate less than that which could be technically and scientifically justified. It is therefore appropriate to emphasize what is likely to be a greater danger. At the present time, we have in the United Kingdom, and in Europe, established schools of particle physicists in excellent standing and perhaps the most talented group of accelerator designers and constructors in the world. If decisions are too long delayed, they may lose heart and be dispersed and our effort will be too little and too late. So the correct *tempo* of development should be given careful and early consideration.

MICROBIAL CLASSIFICATION

A CONFERENCE on the classification of micro-organisms was held during August 30–September 5 at Laval University, Quebec City, Canada. It was organized by the Canadian Committee on Culture Collections and the Numerical Taxonomy Subcommittee of the International Association of Microbiological Societies.

The classification of micro-organisms is of practical importance in many fields, such as medicine, agriculture and food science. Good classifications are here required, but microbial taxonomy is notably difficult, because of the simple morphology of micro-organisms and because our knowledge of their genetics is still scanty. Microbiologists have therefore increasingly turned toward biochemistry and molecular biology for the data they require for classification, and toward computers and other data-processing machines for converting the information into workable taxonomies.

Microbial classification can, however, assist other disciplines in another way; those already mentioned—and many others—all have their own problems of classification. The classifications of disease syndromes and of soils are examples. With the advent of computers it is possible to construct taxonomies by automatic procedures, and workers in other fields are keen to learn from the growing experience of microbial taxonomists, who have been among the pioneers in the new subject of numerical taxonomy. In their turn, microbiologists have much to learn from parallel developments in other sciences.

For these reasons this small informal conference was held, which has made a substantial contribution toward the aims outlined here. The inter-disciplinary approach was fostered by including contributors from biometrics, psychology, botany, zoology, genetics and biochemistry. The programme was a wide one, based on the following outline: classification theory, numerical taxonomy and statistics; techniques and cultures for obtaining the primary data; data-processing methods, together with sessions on nomenclature, identification and genetics. Most of the topics related in the main to bacteria. The discussions were notably lively and profitable.

Dr. P. H. A. Sneath (Medical Research Council, University of Leicester) gave an introduction on the general theory of classification in various fields. He explained the use of the technical terms in numerical taxonomy compared the usage in some other fields, and emphasized the logical sequence of steps in the process of classification. He was followed by Prof. L. L. McQuitty (Michigan State University, East Lansing), who contrasted recent work in psychology, and illustrated many fascinating parallels. He showed how different material required the use of different methods of cluster analysis, and described several novel ones. They were followed by Prof. L. G. Silvestri (University of Milan), who discussed the special problems of the numerical taxonomy of micro-organisms. He discussed the way in which phenetic clusters could be tested for homogeneity and some of the automatic methods for producing diagnostic keys. Dr. F. Möller (Bocconi University, Milan) reviewed the statistical bases for numerical taxonomy, with special reference to information theory, and Dr. F. J. Rohlf (University of California, Santa Barbara) described the different methods of cluster analysis and gave illustrations of their relative advantages. Prof. W. R. Lockhart (Iowa State University, Ames) discussed in some detail the Adansonian practice of giving equal weight to all taxonomic characters, and its influence on coding them for computer analysis, which was also briefly commented on by Dr. Sneath. This problem still raises difficulties in certain groups of organisms, and it is clear that more work is needed in this field.

Another session was devoted to the sources of the primary data needed for classification. Dr. J. M. Shewan (Torry Research Station, Aberdeen) described the problems facing curators of culture collections and emphasized the need for workers to deposit important strains in these collections. Dr. E. F. Lessel (American Type Culture Collection, Rockville, Maryland) and Dr. I. Marcovici (International Centre of Type Cultures, Lausanne) then outlined the present position in bacteriological nomenclature. Many bacteria have no type strains, and the whereabouts of existing types is often unknown, so that lists of types and neotypes (which are now being prepared) will be valuable for future work. From this an interesting discussion, led by Prof. J. Liston (University of Washington, Seattle), developed on the way in which numerical taxonomy could provide criteria for choosing typical strains to serve as neotype cultures where the

original type cultures were unavailable. The procedure for proposing and validating neotypes was also considered. The median organism and the centrotype concepts are here suitable, but although they serve to describe the centre of phenetic clusters they have less power to define their borders, and various suggestions were made on how this might be done.

The conference then went on to discuss the kinds of information which can be obtained from biochemical tests and to the problem of standardizing them. This latter problem is a difficult one, and Prof. V. B. D. Skerman (University of Queensland, Brisbane) introduced this. Discussion on this was rather inconclusive, and it is evident that a huge task faces microbiologists if they are to bring order into the field. There seemed to be a general feeling that test methods for each major group of bacteria would need standardizing for that group, but the problem of reliable comparisons between major groups was more difficult. Several speakers emphasized that descriptive taxonomic tests required different treatment from rapid diagnostic tests for identification; the latter were best devised after sound taxa had been established on the basis of the former, and diagnostic tests could and should be devised for their own special purposes. Dr. O. Lysenko (Institute of Biology, Prague) also made a plea for some standardization in the descriptions of bacteria (as is now being considered in the Actinomycetes), which would avoid many of the present difficulties due to inadequate descriptions in taxonomic studies.

Prof. J. De Ley (State University, Ghent) went on to describe the comparative biochemistry of micro-organisms, and pointed out that there are large areas that were untapped for taxonomic work, either because the comparative biochemistry was not yet known, or because the techniques were not familiar to most microbiologists.

Dr. Rita R. Colwell (Georgetown University, Washington, D.C.) and Dr. R. Hugh (George Washington University, Washington, D.C.) described the practical organization of a laboratory for taxonomic studies. They were followed by Prof. O. B. Weeks (University of Idaho, Moscow, Idaho) and Dr. Muriel E. Rhodes (University College of Wales, Aberystwyth), who illustrated the theme with two particular examples—pigment and flagella respectively. Dr. L. Colobert (Centre de Recherches du CRSSA, Lyon) demonstrated a handy device for rapid testing.

The next session dealt with modern data-processing machines, lucidly described by Dr. F. J. Rohlf. Prof. Skerman discussed the setting-up of a world data centre for bacteriology, and Dr. C. Quadling (Biosciences Division, National Research Council, Ottawa) gave details of the punched-card system being introduced by the Canadian Committee on Culture Collections. Merging with this was a session on identification and how data-processing equipment can assist. Dr. K. J. Steel (National Collection of Type Cultures, Colindale, London, N.W.9) reviewed the prospects here, and described the wide range of identification techniques that are now available. Papers were read on behalf of Dr. L. C. Payne and Mr. D. A. Franklin (Elliott Medical Automation, Boreham Wood, Herts.) and Dr. W. Dybowski (Medical Laboratory Centre, Eastcote, Middlesex) describing a computer system that—from the test results on an unknown organism and the accumulated knowledge of bacteria stored in the computer memory—will print out the most likely alternatives together with any new tests that may be needed for confirmation of the identification. Several speakers touched on the central role of computers in the future, whether on-line in hospitals and laboratories for swift diagnosis, or handling the output of the automated testing machines that are being planned, or in the numerical taxonomy of micro-organisms and the production of diagnostic keys and tables for those without ready access to computers. The logical necessity for constructing classification before identification schemes was also emphasized.

The contribution of genetics and molecular biology to taxonomy was a particularly interesting topic, provoking much lively discussion. It was introduced by Dr. M. Mandel (Anderson Hospital, Houston, Texas). He showed how *GC* base ratios of DNA could contribute toward deciding if major groups were homogeneous and could also indicate possible taxonomic affinities; he went on to discuss the practical difficulties of work on nucleic acid homology by base pairing—a field which potentially has great possibilities in taxonomy by revealing fine genetic homology. Dr. Colwell, Prof. De Ley and Dr. Lily Jones (University of Minnesota, Minneapolis) described their recent findings in the field, and an interesting point that emerged was that strains that are phenetically typical of a cluster were also, as far as present experience goes, typical in *GC* content.

The conference ended with a session led by Prof. M. P. Starr (University of California, Davis) and Prof. Liston, in which participants from different disciplines summed up their reactions, and consideration was given to the future support of work in microbial classification. There was enthusiasm for arranging a second such conference in a few years' time. The proceedings of the present meeting will not be published in full; but it is hoped that the original work presented will be published in the appropriate journals. The conference was supported by the National Research Council of Canada, the U.S. National Science Foundation and the American Society for Microbiology.

OBITUARY

Dr. Eric W. Buxton

Eric Buxton's friends the world over will be grieved to learn of his death at Harpenden on August 4, 1964, at the age of thirty-eight years. His illness, which lasted for over a year, cut short a brilliant career in plant pathology.

Eric William Buxton was born at Ripley in Derbyshire on June 9, 1926. He joined the Royal Air Force in 1944. In 1948 he went up to Cambridge where he gained a double first in the Natural Science Tripos, specializing in botany. He was awarded the Aldis scholarship at Trinity Hall in 1950, and later held a College research scholarship and an Agricultural Research Council studentship, during the tenure of which he worked at the Botany School under the supervision of Dr. (now Professor) Noel F. Robertson, with a 6-month interlude while he studied in Glasgow under Prof. G. Pontecorvo. These experiences expanded his early work on diseases of *Gladiolus* into the wider problems of pathogenicity and genetics of the genus *Fusarium*. In 1954 he came to the Plant Pathology Department at Rothamsted Experimental Station, and rapidly gained international esteem for the new ideas he brought to the study of plant pathogenic fungi in the soil. By pairing avirulent mutants, produced by ultra-violet irradiation of virulent isolates of *Fusarium* from wilted peas, he obtained heterokaryons that were as virulent as the wild-type, and he suggested that such heterokaryons might arise naturally in the soil before invasion of a host plant, thus forming, from originally non-pathogenic clones, pathogenic heterokaryons that would break up again when the fungus sporulated on dead host tissue and so might escape detection. Further, he showed that

nutritionally deficient mutants can attack resistant varieties of host if the appropriate nutrient is supplied with the inoculum.

Parasexual recombinations within heterokaryons of pea-wilt and banana-wilt *Fusaria* were indicated as one source of variability. The terminal cell in *Fusarium* was shown to be multinucleate and therefore potentially heterokaryotic, and Buxton suggested that a few pathogenic nuclei might survive in heterokaryons containing predominantly nuclei adapted to saprophytic existence in mycelia growing saprophytically in soil. Avirulent mycelia could thus constitute a reservoir from which pathogenic forms, with mainly pathogenic nuclei, could arise when selectively favoured by the proximity of a host plant. Buxton's work on pea-wilt threw important light on the mechanisms of resistance and susceptibility of plant to fungus by showing that exudates from roots of one variety of pea can inhibit growth of a race of *Fusarium oxysporum* f. *pisi* to which that variety is resistant, but stimulate another race to which it is susceptible. Further, he showed that when conidia of race-1 were held for 14 days in concentrated root exudates from a host plant resistant to race-1, some were modified into race-2 pathogenicity. Genetic variability was Buxton's prime interest, but he was no narrow specialist; his 40 publications show his unusual versatility, as he was equally able and productive in practical work on disease control as in more academic studies. He also served as Secretary to the British Mycological Society's Plant Pathology Committee, and was on the Editorial Board of the *Journal of General Microbiology*.

With the award of a Kellogg Foundation fellowship, Buxton made his first visit to the United States in 1957. In 1958 he returned as the guest of the American Phytopathological Society to contribute to their golden jubilee meetings at Bloomington, Indiana, and in 1960 he went at the invitation of the United Fruit Co. to work for a year in their laboratories at Norwood, Mass., on *Fusarium* wilt of the banana.

His stimulating conversation, his ability to teach and his friendly personality explain why Buxton's laboratory was sought, not only by his colleagues, but also by visitors from other parts of the world. In 1950 he married Doreen Hampson of Ripley, Derbyshire, who survives him with their three sons. He gave to his family life the same zest as his research.

P. H. GREGORY

NEWS and VIEWS

Directorship of the Commonwealth Mycological Institute: Dr. J. C. F. Hopkins, C.M.G.

DR. J. C. F. HOPKINS, who retired on September 30 from the directorship of the Commonwealth Mycological Institute, Kew, a position he had held since 1956 (*Nature*, 178, 1150; 1956), is well known as a versatile tropical plant pathologist. After service in the Royal Air Force during the First World War, he graduated from the University of London and continued his training in Trinidad at the Imperial College of Tropical Agriculture. For the next two years he worked in Uganda, then moved to Southern Rhodesia, where in the course of twenty-eight years he was successively mycologist, senior plant pathologist, and finally chief botanist and plant pathologist. An authority on diseases of tobacco in Africa, and the author of the standard book on this subject, Dr. Hopkins's services have been in much demand, and during recent years he has travelled widely both as a consultant and on behalf of his Institute and the Commonwealth Agricultural Bureaux. Under his directorship, in addition to a general expansion of the work of the Institute, a unit for the identification of plant pathogenic bacteria was successfully initiated. Dr. Hopkins has taken an active interest in the affairs of the Institute of Biology and besides serving on the Council has acted as chairman of the London Branch. In 1962, in recognition of his public services, Dr. Hopkins was appointed a Companion of the Order of St. Michael and St. George.

Dr. G. C. Ainsworth

DR. G. C. AINSWORTH, who has been appointed to succeed Dr. J. C. F. Hopkins as director of the Commonwealth Mycological Institute, obtained a London first-class honours degree in botany in 1930 and was awarded a Ph.D. in 1934. He showed an early interest in medicine, obtaining a Ph.C. in 1929 and was awarded the Pharmaceutical Society's silver medal and the Harrison Memorial Prize. From 1930 until 1939 he studied plant diseases at Rothamsted and Cheshunt, where he specialized in crop diseases, particularly those due to viruses. He was then appointed to the Commonwealth Mycological Institute and helped in the production of the *Review of Applied Mycology*; he also prepared a monograph on the British Ustilaginales. After the Second World War, his earlier interests became evident again and he was appointed head of the Mycological Department at the Wellcome Research Laboratories working on antibiotics and developed research on the mycoses of man and animals. As a natural consequence, he was soon appointed a Wellcome Trustees Research Fellow in medical mycology at the London School of Hygiene and Tropical Medicine, and his insistence on accurate identification and correct nomenclature from that time onwards has had a marked effect on the development of this discipline, especially under the sponsorship of the Mycology Committee of the Medical Research Council, of which he was secretary for ten years. In 1948, he was appointed lecturer in botany at the University College of the South West of England (now University of Exeter), and was promoted reader in 1951. He continued his researches into the mycoses of animals, and the records of a two-year survey, supported by the Agricultural Research Council, of mycotic diseases of farm animals in Britain were transferred to the Central Research Laboratory, Weybridge, as the basis for a new veterinary mycology unit. But the call of the Commonwealth Mycological Institute proved too strong and he returned there to be made, in 1961, assistant director. He has been president of the British Mycological Society, but is probably best known throughout the world as the author of *The Dictionary of the Fungi*, the fifth edition of which has recently been published.

Registrar and Secretary to the Council for National Academic Awards: Mr. F. R. Hornby, M.B.E.

MR. F. R. HORNBY has been appointed registrar and secretary to the Council for National Academic Awards. Mr. Hornby was educated at Heversham Grammar School, Westmorland, and Magdalene College, Cambridge, where he obtained first-class honours in the Natural Science Tripos, Parts I and II. He has taught in Highbury County Secondary School, London, and at Taunton School, Somerset. During the Second World War he served with the Royal Army Ordnance Corps and the Royal Army Education Corps, and attained the rank of Lt.-Colonel and was awarded an M.B.E. for services in North Africa and Italy. Before he became secretary of the National Council for Technological Awards in 1956 he was assistant education officer in the City of Nottingham Local Education Authority.

The charter and statutes of the new Council for National Academic Awards were published on September 25, and

the first meeting was held on September 30. The appointment of Sir Harold Roxbee Cox, formerly chairman of the National Council for Technological Awards, was announced earlier this year (*Nature*, 201, 975; 1964) and the names of the other twenty-one Council members in July. The Robbins Committee in its report on higher education recommended that the National Council for Technological Awards should be replaced by the Council for National Academic Awards. The new Council has a wider role. It is able to award higher as well as first degrees, and in subjects other than technology; it is to provide for part-time, as well as full-time and sandwich course, students. Moreover, it is to be concerned with Scotland as well as England and Wales.

Scientific Research in Belgium

The fourth annual report of the National Council for Scientific Policy, Brussels, covers the year ended November 30, 1963 (Pp. 212. Bruxelles: Conseil National de la Politique Scientifique, 1964). It is in two parts: the first, in six chapters, deals with the activities of the Council during the period and in the perspective of future needs and policy; the second presents a chronological record of the activities of the Council and its constituent organs during the period, and appended are the constitution of the Council, and details of its membership and that of its committees and working groups and study groups. The six chapters of Part 1 deal successively with the development of scientific policy at the national and at the international level, the scientific budget, the organization of research, the expansion of higher education, the scientific establishments, and scientific careers. The scientific budget for 1963 provided credits amounting to 4,539 million francs, an increase of 459 million francs on 1962. This was distributed by ministries as follows (in millions of francs): education, 2,417; economic affairs, 1,432; agriculture, 189; defence, 151; Prime Minister's office, 141; public works, 92; public health, 91; foreign affairs, 12; other departments, 14. By institutions the distribution was: universities and institutions of higher education, 2,539 (of which 666 was for research); scientific establishments of the State, 850; establishments of public utility, subsidized by the State (Study Centre for Nuclear Energy), 792; industrial concerns and co-operative centres, 242; miscellaneous, 116. Expenditure on fundamental research was estimated at 1,594 million francs, of which 461 million francs was for the exact sciences, 292 million francs for the medical sciences, 204 million francs for nuclear science, and 138 million francs for biology and other natural sciences. Of 1,630 million francs for applied research, 359 million francs was for industrial research, 289 millions for agronomic research, 850 millions for nuclear research, and 56 million francs for space research. During the year, four working groups were established for the development of nuclear, medical, advanced technological and space research and of social science, respectively. Annexed to this part of the report is a survey of the national scientific potential in 1961, which estimates the effective scientific manpower in that year as 22,509 full-time workers in 1,644 scientific units. Of these, 6,703 held a university degree, 2,451 an advanced technical diploma, and 13,350 were technicians or craftsmen. Of the university graduates, 3,623 were employed in education, 1,100 in the public sector, 1,437 in private enterprise, 328 in research associations in industry and agriculture, and 143 in interuniversity centres; by sciences, 604 were in physics, 496 in chemistry, 764 in biology, 1,064 in medicine, 255 in geology and Earth sciences, 95 in mathematics and 2,136 in technology, with 821 in the social sciences.

The University Foundation, Brussels

The forty-third annual report of the University Foundation, Brussels, for the year ended September 30, 1963, records grants to new students totalling 94,000 francs, and a further 420,000 francs for study in scientific establishments overseas (Pp. 164. Bruxelles: Fondation Universitaire, 1964). Subsidies to scientific publications totalled 815,000 francs, with a further 2·28 million francs in support of learned periodicals in Belgium and 961,000 francs in subsidies to scientific associations and institutions. The Documentation Service arranged exchanges with 41 overseas institutions, and 255 foreign reviews were deposited in Belgian scientific libraries in exchange for a similar number of Belgian reviews. The *Index of Periodical Publications* now covers 42,000 periodicals, compared with 27,000 in 1935. Besides details of the grants and subsidies awarded, scientific prizes, and other activities of the Foundation, the report includes details of its relations with other bodies, membership of the Council, Secretariat and Commissions, and the text of the rules governing its activities and awards.

The Mauritius Sugar Industry Research Institute

The annual report of the Mauritius Sugar Industry Research Institute for 1963 is a very creditable publication both in contents and form (Pp. 153+xxxii. Reduit: Mauritius Sugar Industry Research Institute, 1964). It reflects the high standard of the Research Institute and, indirectly, also that of the industry as a whole, which has increased its sugar production from 491,000 tons in 1954 to 682,000 tons in 1963. Eighty-four pages are devoted to the cultivation of the cane, twenty-seven pages to the sugar manufacture, and six pages to by-products. Each section describes interesting work of value to the local industry, but little that might be applicable to other sugar cane growing areas.

Skill and Capital in Horticulture

The short article, "Investment in Skill", contributed by Dr. R. R. Folley to the *Westminster Bank Review*, August 1964, is concerned with the effect of the Agriculture and Horticulture Act, which makes grants available to assist horticulturists to improve their capital equipment. He stresses the need to match this increase in capital equipment with a higher degree of individual skill. Skill, he urges, is to be preferred to scale, particularly in the intensive branches of the industry, where the product, whether fruit, flowers or the less common vegetables, is improvable in quality, and where value and price are sensitive to even small improvements. Dr. Folley quotes, as an example, annual savings amounting to £1,558,000 to be achieved by raising the yield of apples from 250 to 350 bushels per acre, with reduction in acreage from 64,000 to 45,500, on an expenditure of £7,651,000 for the lower yield.

Growth of Scientific Literature

Papers presented at the thirty-eighth annual conference of the Association of Special Libraries and Information Bureaux (Aslib) at the University of Exeter, during September 28–October 1, were for the most part somewhat specialized, but Sir Thomas Scrivenor's discussion of the growth of scientific literature is of more general interest. He challenges the validity of some estimates of the rate of growth, pointing out that secondary publications, although included in the *World List of Scientific Periodicals*, should not, strictly speaking, be taken into account in measuring the volume. There is also room for more than one opinion on what should be regarded as a deceased publication. He recognizes that it may not be easy to achieve an agreed definition of what constitutes a scientific publication, but suggests that a modified version of the *World List* would meet the situation. This should be published regularly every five years, titles of all periodicals neither scientific nor technological being eliminated, and all entries numbered in series straight

through to permit accurate reckoning of totals without delay. Sir Thomas also suggests replacing the present arrangement of entries in alphabetical order by one in which they are grouped by subjects and possibly by languages within each subject: such an idea would probably be more acceptable if such a list supplemented the present alphabetical form.

The Indian Journal of Cancer

THE first issue of the attractively produced *Indian Journal of Cancer* appeared in October 1963. Edited by Dr. D. J. Jussawalla for the Indian Cancer Society, Hospital Avenue, Parel, Bombay, and printed in Bombay, the *Journal* is produced on glossy paper, with good illustrations. The editor is fortunate in having the assistance of 57 British, American, Japanese and Indian experts who constitute the international Editorial Advisory Board. The first issue contains ten articles on various aspects of the cancer problem (1, No. 1; October 1963. Issued twice a year. Pp. xxviii+1–90. Bombay: Indian Cancer Society, 1963. Annual subscription, Rs. 6, post free). The future of the *Journal* will be watched with interest by all who are concerned with the world-wide effort to understand the causes underlying the occurrence and development of malignant growths and to prevent their occurrence and mitigate their effects on man and other animals.

National Research Council of Canada

THE *Review of the National Research Council of Canada*, 1964, contains besides the usual reports on the work of the several Divisions, with lists of publications during 1963–64 and of the Medical Research Council, reports from the various Committees of the Council with details of the membership of the Council and its Committees. There is also a directory of staff and a list of staff serving on outside organizations.

Royal Scottish Museum, Edinburgh

THE annual report for 1963 of the Royal Scottish Museum records the urgent need for additional accommodation and the promised reconstruction of the north-east and north-west wings. It has been decided that the greater portion of the reconstructed north-east wing will be given to an introductory Hall of Biology which is being designed by the Departments of Geology and Natural History. Notable purchases included a silver cake basket by William Dempster, Edinburgh, 1747. In the Department of Natural History exhibition work has been concentrated on the reconstruction of the exhibits in the British Animal and Bird Halls. The major exhibition work in the Department of Geology has been the preparation of cases illustrating general mineralogy. Coastal and glacial scenery has also been dealt with in a series of photographs, and the regional geology of the Carboniferous of the Midland Valley of Scotland has been illustrated.

The National Health Service

FOUR surveys conducted by Research Services, Ltd., show that 88 per cent of the general public think that the National Health Service is, on the whole, working well. Seven out of ten believe that treatment in hospital and treatment by the patient's own doctor under the National Health Service compares well with that in other countries. Two per cent take the opposite view. These attitudes have not changed significantly over the past two years (*Attitudes Towards the National Health Service Amongst Family Doctors and the General Public*, 1962 and 1964). In contrast, the proportion of family doctors expressing general satisfaction with the Health Service fell from 79 per cent to 62 per cent between 1962 and 1964. The fall was greater among those under the age of forty-five, for whom the proportion expressing satisfaction dropped from 83 per cent to 59 per cent. There was a big increase between 1962 and 1964 in the number of ways in which family doctors wanted to see the National Health Service improved. In 1964, 21 per cent of doctors wanted improved terms of service, or arrangements for provisions of locums; 13 per cent wanted better hospital facilities; 10 per cent wanted ancillary help; and 5 per cent wanted the provision of health centres or group practice premises. Other improvements suggested in both years included a reduction in the number of patients per doctor, mentioned by 14 per cent, and the need to educate patients to avoid abuse of the service, mentioned by 12 per cent. Despite their present discontent, general practitioners in 1964 seemed to think there was rather less risk of their becoming subordinate medical auxiliaries than they had appeared two years earlier.

International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in the *Bulletin of Zoological Nomenclature* (21, Part 4; published on October 16, 1964): (1) Suppression of *Mus canguru* Muller, 1776 *et al.*, and *Jaculus giganteus* Erxleben, 1777; validation of *Macropus major* Shaw, 1800 (Mammalia). *Z.N.(S.)* 1584. (2) Designation of a type-species for *Curimata* Bosc, 1817 (Pisces). *Z.N.(S.)* 1590. (3) Designation of a neotype for *Belemnites mucronatus* Link, 1807 (Cephalopoda). *Z.N.(S.)* 1160. (4) Suppression of the specific name *Echinus rosaceus* Linnaeus, 1758, 1764, 1767, and Gmelin, 1788, and of the generic name *Echinanthus* Leske, 1778 (Echinoidea). *Z.N.(S.)* 1616. (5) Suppression of *Nana* Schumacher, 1817 (Gastropoda). *Z.N.(S.)* 1622. (6) Validation of *Sphalerosophis* Jan, 1865 (Reptilia). *Z.N.(S.)* 1627. (7) Emendation to *Astraeus* of the generic name *Asthraeus* Laporte and Gory, 1837 (Insecta, Coleoptera). *Z.N.(S.)* 1628. (8) Validation of *Rhyncogonus* Sharp, 1885 (Insecta, Coleoptera). *Z.N.(S.)* 1629. (9) Validation of *Ambalodus* Branson and Mehl, 1933 (Conodont). *Z.N.(S.)* 1633. (10) Validation of *Cnemidophorus septemvittatus* Cope, 1892 (Reptilia). *Z.N.(S.)* 1634. (11) Suppression of *Procyon brachyurus* Wiegmann, 1837, and *Procyon obscurus* Wiegmann, 1837 (Mammalia). *Z.N.(S.)* 1640. Any zoologist who wishes to comment on any of the foregoing cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S.W.7, before April 16, 1965.

Texas Instruments

THE annual meeting of Texas Instruments Inc. was held in Dallas on April 15, 1964, and some 800 shareholders were present. The president, Mr. P. E. Haggerty, reported on the company's activities (*Texas Instruments Incorporated, 1963 Annual Report*. Pp. 12. Dallas: Texas Instruments, Inc., 1964). Net sales amounted to 276·5 million dollars, 15 per cent higher than in 1962, and this increase has continued into 1964. Semiconductor components, including transistors and diodes, were again the largest contributor to the profits. One hundred and sixty new products were introduced—in particular, a series of ultra-high-frequency tuner transistors for television receivers, low-cost silicon diodes, and electronic devices for the *Minuteman* intercontinental ballistic missile and the *Polaris* missile. Semiconductor integrated circuits, which the Company was the first to introduce, consist of both amplifier and high-speed computer types, and may include as many as 40 different component equivalents.

The sale of materials and control systems increased. An electronic control system for home clothes-dryers was one of the new products introduced during the year, and

the manufacture of semiconductor silicon material continued on a profitable basis despite considerable market price pressure. The production of nuclear fuel elements and cores, mainly for the Navy's propulsion programme, also continued. Texas Instruments is the main contractor for the electronic equipment of the naval *Shrike* air-to-surface missile, and the programme has now advanced from the development to the manufacturing stage. Prototype advanced radar and infra-red systems for the Air Force's new reconnaissance fighter aircraft *RF4C* were delivered, with production scheduled for 1964. New sales records were established by the Company's petroleum exploration activities and in applications of Earth, ocean and space sciences. Contracts were obtained to develop a major multi-sensor shipboard survey system which will perform and record simultaneously many oceanographic tests such as those for temperature, gravity and magnetic measurements, and to find the best methods to make scientific measurements and geophysical investigations during the Apollo visit to the Moon. Expenditure on development or application of new or modified products, services, equipment or processes totalled about 45 million dollars, of which about 25 million dollars was from outside contracts, mainly with the Government of the United States. Business in Europe exceeded expectations, and was good both in Latin America and Australia. Texas Instruments France moved into a new 60,000 ft.^{2} semiconductor plant near Nice and an additional plant of 59,000 ft.^{2} for metal fabrication was leased in Australia. A new plant was opened at Toronto, Canada, for control device manufacture, and construction will shortly begin on a similar plant near Aversa, Italy. Approximately 18 per cent of the total net sales of the Company were from operations in countries outside the United States.

Preparation and Properties of *bis*-Hydrazides and Related Compounds

C. N. O'Callaghan and Dermot Twomey, of the Medical Research Council of Ireland, Trinity College, Dublin, have described the preparation and properties of *bis*-hydrazides and related compounds (*Proceedings of the Royal Irish Academy*, 63, Section *B*, No. 12: *Anti-tubercular Substances*; 19: *The Preparation and Properties of bis-Hydrazides and Related Compounds*. 1964. 1*s*. 6*d*.). Since the discovery of the anti-tuberculosis properties of isoniazid, considerable attention has been directed to the preparation of compounds containing hydrazide groupings. Apart from mono-hydrazides, anti-tuberculosis properties have also been ascribed to various *bis*-hydrazides and structurally related compounds. One of the latter, cyanoacetohydrazide, has been thoroughly examined; despite conflicting reports, it is now generally considered to be much less active *in vivo* than isoniazid. A feature of compounds such as ethyl malonate, ethyl cyanoacetate and ethyl acetoacetate, which contain a reactive methylene group, is the ease with which they undergo the well-known Knoevenegel reaction with aldehydes and ketones to yield a series of compounds of type I, where R is CO_2Et, CN and $COCH_3$, respectively. The reaction of these condensation products with hydrazine has been investigated.

British Geological Literature

Among the recommendations of the British Commonwealth Official Conference on Geology and Mineral Resources, which met in London in 1948, there is one that "The Geological Survey (or other appropriate authorities) throughout the British Commonwealth should each take steps to publish an annual volume of abstracts of all geological papers published relating to the territories for which they are respectively responsible". In most Commonwealth countries this proposal has long since been implemented; but in Britain not even an annual bibliography of geological works, far less a volume of abstracts, has been available in post-war years. A special welcome must therefore be extended to a new unofficial publication, *British Geological Literature*, compiled by E. L. Martin, of the Geological Survey, and A. P. Harvey, of the British Museum (Natural History), the first part of which lists nearly 300 references published early in 1964. *British Geological Literature* (Coridon Press, 35 Goddington Road, Bourne End, Bucks. £1 per annum) will be published quarterly, with annual author and subject indexes; and a loose-sheet edition for card-index catalogues is also being produced. The compilers are to be congratulated on their initiative, which deserves every support. Perhaps it is not too much to hope that their modest publication may expand into the much-needed journal of abstracts which the appropriate authorities have as yet been unable to produce.

Last Cretaceous Vertebrates

Two papers recently issued as *University of California Publications in Geological Sciences* add much to our knowledge of the vertebrate faunas near the critical Mesozoic–Cenozoic boundary. In a re-investigation of the Lance Formation in Wyoming, Dr. R. Estes reports on the palæoecology and zoogeography with details of the non-mammalian vertebrate fauna and a brief account of the flora and invertebrate fauna (49: *Fossil Vertebrates from the Late Cretaceous Lance Formation, Eastern Wyoming*. Pp. 180 + 5 plates. Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1964. 4 dollars). Dr. W. A. Clemens deals with the Multituberculata in the first part of a publication and will deal with the metatherians and eutherians in later parts (48: *Fossil Mammals of the Type Lance Formation, Wyoming*. Part 1: Introduction and Multituberculata. Pp. 1–105. Berkeley and Los Angeles: University of Cailfornia Press; London: Cambridge University Press, 1963. 2.50 dollars). The authors have been fortunate in obtaining extensive new collections by underwater screening of the matrix, so concentrating a microfauna of more than 30,000 specimens. Five multituberculate genera, including a new species, are described and all referred to the Ptilodontidae. The reptile fauna comprises an eosuchian, six turtles, fourteen lizards, a snake, two crocodiles and eight dinosaurs, the latter with theropods, carnosaurs and ornithischians. A good amphibian fauna is represented by both salientes and urodeles. The fish include sharks, sturgeon, amiids and gar. Estes is able to confirm the fresh-water character of the formation investigated, with sub-tropical climate prevalent. The environment envisaged is a warm, humid, coastal plain with abundant riparian habitats and rich vertebrate fauna. The remaining parts of these investigations will be keenly awaited, the rare combination of Mesozoic and modern elements in the biota making it of especial interest.

Locomotion in Antarctic Seals

Fergus O'Gorman, of the British Antarctic Survey and the Anatomy Department, Charing Cross Hospital Medical School (London), has made observations on the modes of terrestrial locomotion among Antarctic members of the Phocidae (*Proc. Zool. Soc. London*, 141, Part 4; 1963). An account is given of the sinuous or 'swimming' type of progression which is particularly developed in the crab-eater seal, *Lobodon carcinophagus* (Hombron and Jacquinot), and is also seen in the leopard seal, *Hydrurga leptonyx* (Blainville). This type of movement has not been seen in the Weddell seal, *Leptonychotes weddelli* Lesson, where the undulatory (caterpillar-like) method is the normal locomotory pattern on land. The fore-flippers are not used by the adult Weddell seal in terrestrial locomotion, but the pup does make some use of the fore-flippers during its first 10–15 days.

A Dangerous New Stonefish from Western Australia

A NEW species of the genus *Inimicus*, belonging to the family Synanceidae from Western Australia, has been described by R. J. McKay, of the Fisheries Department, Perth, Western Australia, and compared with other members of the genus (*Journal of the Royal Society of Western Australia*, 47, Part 1; 1964). *Inimicus cirrhosus* differs from all others of the genus in that it possesses yellow spots on the inner surface of the pectoral fin, which is described as "dark brown, almost black with indistinct pale cross-bars and variable blotches on outer surface. Inner surface brown to blackish, with 20 to 35 white (in life bright yellow) spots of indefinite shape". In larger examples, the yellow spots are more diffuse and frequently in the form of ocelli. McKay adds some notes on the severity of the sting: the species is capable of inflicting an extremely agonizing wound. The following notes were made early in October 1960, after the author was stung on the thumb. "The pain was immediate and intense, the wound bled very freely for a few minutes, then ceased. Bleeding was difficult to restart. Pain became rapidly unbearable. 1145 h. While sorting a trayful of fish emptied from trawl left thumb deeply penetrated by dorsal fin of *Inimicus*. Bleeding freely. 11.50 h. Bleeding stopped. 1155 h. Thumb swollen, area around wound becoming grey-blue in colour, extremities of fingers becoming very painful, pain in thumb almost unbearable. Elbow and shoulder now aching. 12 midnight. Sweating profusely, thumb and hand swollen, wrist very stiff, area around wound bluish, throat and mouth dry. 0005 h. Became delirious, do not remember much, but can remember throwing myself about cabin in fearful pain. Crew members restrained my movements for the next 30 minutes, during which I was screaming and complaining of pains around the neck and chest. 0045 h. Regained consciousness, the pain in arm and shoulder very agonizing. 0115 h. Hand and thumb immersed in hot water and sedatives taken. 0200 h. Pain still present but greatly diminished. Thumb remained stiff and swollen for four days, but the pain had subsided 12 hours after the encounter. Bathing the wound in hot water greatly reduced the pain, but when the water became cool enough to be comfortably borne, the pain returned. A tourniquet was not applied."

Rhizobial Nitrogen Fixation in African Acacias

RHIZOBIAL nitrogen fixation, previously reported in *Acacia cyclops*, has also been shown to occur in *A. cyanophylla* by Prof. E. R. Roux and C. C. G. Marais (*South African Journal of Science*, 60; July 1964). These trees are invasive exotics of Australian origin, now widespread in the Western Cape. Root nodules have so far not been found on any of the indigenous South African acacias examined. However, four species (*A. karroo*, *A. robusta*, *A. sieberiana* and *A. giraffae*) were successfully inoculated with rhizobia derived from nodules on *A. cyclops*. Nodule formation and nitrogen fixation occurred in all cases.

University News :

Aberdeen

THE following appointments have been announced: *Senior Lectureships*, A. E. Bursill and J. J. Cowley (psychology). *Lectureships*, Dr. J. M. Hay, Dr. J. H. Holloway and Dr. G. P. McQuillan (chemistry); J. Henderson (forestry); C. K. Mackay and G. Rochford (psychology); G. A. Myers (statistics). *Research Fellowships*, I. Patterson (natural history); Dr. J. Paul (soil science).

Belfast

DR. I. CAMPBELL RODDIE has been appointed to the Dunville chair of physiology in the Queen's University of Belfast.

Sheffield

DR. J. M. GANI, visiting professor of statistics, Michigan State University, has been appointed to the chair of statistics. The following appointments have also been announced: *Lectureships*, Dr. D. J. Brown (fuel technology and chemical engineering); C. C. Heyde (statistics); Dr. N. Birks (metallurgy); F. Booth (applied mathematics); J. K. Clarkson (psychology); G. J. Roberts (glass technology); G. Sedman (psychiatry); T. Shelley (medical physics in the Department of Obstetrics and Gynæcology). *Research Fellowships*, A. T. Davenport (Ironmongers' Company research fellowship in metallurgy); F. Wallstrom (sociological studies).

Announcements

MR. R. F. LETHBRIDGE, head of the Mining and Exploration Department of the Rio Tinto-Zinc Corporation, Ltd., has been elected president of the Institution of Mining and Metallurgy for 1965–66. Mr. Lethbridge has served on the Council of the Institution since 1955, holding the office of vice-president from 1963.

ENTRIES for the 1965 Maccabaean Prize and Medal of the Worshipful Society of Apothecaries are invited for an essay of 5,000–7,000 words on some aspect of the history of medicine or pharmacy. Intending candidates, who must be under thirty years of age on March 15, 1965, may apply for further particulars to Dr. F. N. L. Poynter, Wellcome Historical Medical Library, Wellcome Building, Euston Road, London, N.W.1, who is honorary secretary of the Faculty of the History of Medicine and Pharmacy of the Society.

THE second Texas symposium on "Relativistic Astrophysics" will be held in Austin, Texas, during December 15–18. Further information can be obtained from Mrs. J. Wardlaw, Department of Physics, University of Texas, Austin, Texas 78712.

THE twenty-second session of the International Geological Congress will be held in New Delhi during December 14–22. Further information can be obtained from the Secretary General, XXII International Geological Congress, Geological Survey of India, 27 Chowringhee, Calcutta 13.

THE third conference on "Performance of High Temperature Systems" will be held in Pasadena, California, during December 7–9. The conference will be devoted primarily to the application of fundamentals to the analysis and computer evaluation of the performance of high-temperature systems. Further information can be obtained from Mr. G. S. Bahn, 16902 Bollinger Drive, Pacific Palisades, California 90272.

THE 1964 Reith Lectures will be delivered by Sir Leon Bagrit in the B.B.C. Home Service on "The Age of Automation". The series will include lectures on: automation, an extension of man (November 8); the range of applications (November 15); education for an age of automation (November 22); some political considerations (November 29); some industrial and economic consequences (December 6); new opportunities for social enrichment (December 13). The Lectures will be repeated in the Third Programme and will also be heard in the Overseas Service. Further information can be obtained from the British Broadcasting Corporation, Broadcasting House, Portland Place, London, W.1.

ADDENDUM. Mr. J. Liebster has supplied the following references which were omitted from his joint communication with V. Kočandrle entitled "Exchange Labelling of 'Lipiodol' Ultra Fluids with Iodine-131 and its Intralymphatic Administration with a Fistula on the Thoracic Duct" (*Nature*, 203, 777; 1964):

REGIONAL ORGANIZATION OF RESEARCH IN AUSTRALIA AND SOUTH-EAST ASIA

THE concept of the development of scientific research on a regional basis is one which has long been advocated by Unesco, and followed in the operations of its field science co-operation offices. The South-east Asia Science Co-operation Office has been active in stimulating collaboration and co-operation in a number of scientific fields in its region, and has been responsible for two important meetings—in Bandung in 1959 and in Hong Kong in 1961. Representatives of national research councils in the area met to discuss general problems of organizing scientific research (see *Nature*, 186, 859, 1960; 194, 626, 1962). More recently, in February 1964, a third meeting was held in Canberra, Australia, for a similar purpose, the local arrangements being made by the Australian Commonwealth Scientific and Industrial Research Organization.

The Canberra meeting enlarged the scope of the earlier meetings, as it included representatives of national research organizations from both South and South-east Asia. Delegates came from Ceylon, China (Taiwan), Hong Kong, Indonesia, India, Israel, Japan, Korea, Malaysia, Nepal, New Zealand, Pakistan, Philippines, Thailand, Viet Nam and Australia. There were also present consultants from India, Indonesia, Japan, the United States, the U.S.S.R. and Australia, and observers from the World Health Organization, the Food and Agriculture Organization, the Pacific Science Association, the Pan-Indian Ocean Science Association and the South Pacific Commission.

Following the United Nations conference on the "Application of Science and Technology for the Benefit of the Less Developed Areas" (*Nature*, 197, 1135; 1963) in Geneva in 1963, Unesco made plans to extend considerably its activities in the field of natural science, and the Canberra meeting was looked on as a regional follow-up to the Geneva conference. It was considerably strengthened by the presence of M. Rene Maheu, the director-general of Unesco, for part of the proceedings and a delegation from Unesco headquarters including Prof. V. Kovda, the director of the Natural Sciences Department. Sir Frederick White, chairman of C.S.I.R.O., was elected chairman of the meeting. Prof. Sarwono Prawirohardjo, president of the Indonesian Council of Sciences, was elected rapporteur.

The meeting, which was held in the Australian Academy of Science building, was opened with an address from Senator the Honourable J. G. Gorton, the Australian minister assisting the Prime Minister in education and research. Mr. Gorton referred to the fact that many developing areas could benefit significantly by the application of scientific facts which were already known, so that it was essential for Governments to provide adequate extension services and ensure the supply of trained technicians.

M. Rene Maheu also addressed the meeting and emphasized what he described as the salient features of the Geneva conference: that countries can scarcely hope to obtain economic independence—and political independence without economic independence is little more than a façade—if their own scientific and technical potential remains below a minimum threshold. A far-sighted governmental policy for science will seek two main objectives: to develop scientific and technical potential on one hand, and, on the other, to apply the creative and assimilative capacities of that potential to the cultural, economic and social progress of the country. The purpose of the Canberra meeting was to define fields of application, and methods of formulating and executing such national scientific policies.

The principal sessions of the meeting covered national science policies, relations between science and Government, research and economic development, investment in research, research organization and administration, and regional collaboration in research and training.

Underlying all the discussions was the question raised by M. Maheu: how best to ensure that science plays its most effective part in the processes of economic development. This involves the setting-up of suitable advisory machinery for government. It will vary according to the stage of the political, economic and scientific development of the country concerned, but must bring the possibilities of science to the notice of the economic planners, and also ensure feed-back of economic problems to research groups. Proper organization and management are essential if science is to flourish and to make an effective contribution to development. At the same time it is necessary to plan educational and manpower development and to ensure the availability of trained men, not only to engage in investigation and research, but also to ensure that research results are put to agricultural and industrial use.

As was to be expected, discussion was largely directed towards the role and activities of Unesco in the regions represented at the meeting. It was clear that there was general appreciation of the work which Unesco has been doing in the various countries concerned, though there was by no means an uncritical acceptance of all its policies. The principal help needed from Unesco was towards building up within each country an organization which would enable it to develop internal solutions to its own problems.

G. B. GRESFORD

ASPECTS OF SOIL SCIENCE

THE eighth International Congress of Soil Science was held in Bucharest during August 31–September 9. The official opening of the Congress was held in the Great Hall of the Palace of the Romanian Peoples Republic by President Gheorghe Gheorghiu-Dej. In his speech welcoming the 1,200 delegates, the Romanian President stressed the need for raising the standards of food production in the world. He complimented the International Soil Science Society for its contribution to this vital work, and for the part it played in the development of understanding and peace.

After the necessary business of the Society had been concluded, the programme of scientific papers began with a general session in which the history and progress of the Food and Agriculture Organization/Unesco project for a World Soil Map were described. Good progress had been made, and hence it was possible for several maps to be exhibited at the Congress. Throughout the nine remaining days of the meeting, more than 700 papers were read to the seven Commissions of the Congress, dealing with soil physics, soil chemistry, soil biology, soil fertility, soil genesis, classification and cartography, soil technology, and soil mineralogy. Abstracts of the papers were made available in English, French and German, and the proceedings of the Congress will be published in the near future.

The papers read in Commission 1 (Soil Physics) dealt with such diverse topics as the physical relationships between the solid and liquid phases of the soil and the relationship of tillage problems to physical properties. Several papers were devoted to investigations of the

movement of water in saturated and unsaturated conditions through the soil. Soil chemists in Commission 2 concerned themselves with fundamental problems of research, and in particular research pertaining to the properties and formation of humus complexes. The importance of chemical change, especially exchangeable cation relationships, associated with soil genesis was also discussed. The investigation of the soil solution assumes even greater importance in the semi-arid areas where salt concentrations are sufficient to affect crop production. The influence of irrigation on saline and alkaline soils was reviewed by delegates from Egypt, Israel, the United States, Spain, Tunis, Hungary, Turkey, the U.S.S.R., and Romania. At the other extreme of the *p*H scale, the moderation of acid soils and their improvement for agriculture were the subjects of several papers. In a joint session with Commission 4 (Soil Fertility) the problems of the chemistry and biochemistry of phosphorus in the soil and in plant nutrition aroused considerable interest.

Problems involved in the examination of soil micro- and macro-fauna were discussed, and of special interest to the non-specialist in this field was the section dealing with the possibility of control of the activity of soil organisms. The variation of the natural environment within the soil and its repercussions on populations of organisms enables the soil biologists to gauge the effects of modern pesticides on the beneficial inhabitants of the soil. Interactions of soil micro-organisms and higher plants were discussed as well as the nature and effect of bacterial fertilizers.

The role and efficiency of fertilizers were the province of Commission 4, and the influence of soil conditions on nutrient availability to plants was discussed, as was the part played by organic matter in soil fertility. The section of the programme dealing with the efficacy of fertilizers on genetic soil types with different crops under irrigated or non-irrigated conditions provided an interesting link with the work of those concerned with soil classification. Many problems arising from the deficiency of major plant nutrients are now fairly well understood and have been remedied in advanced countries. However, the minute amount of the minor elements necessary has become an important investigation: papers read included reference to boron, zinc, molybdenum and sulphur, in various soils.

The most extensive programme was that undertaken by Commission 5 (Soil Genesis, Classification and Cartography). In this section alone more than 160 papers were read. As might be expected, the soils of south-eastern Europe were discussed at some length by delegates from the host country, Romania, and from Hungary and Bulgaria. Other sections were devoted to the origin and genesis of soils of the desert and semi-desert, steppe, mountain and cold regions, tropical, Mediterranean and sub-tropical regions. Progress in soil mapping and cartography was outlined by speakers from many different parts of the world.

Soil technology is never far removed from the fundamental investigations of soil chemistry and physics, and it was no surprise to find that there were joint sessions of Commission 6 with Commissions 1 and 2. Soil erosion is always a danger, particularly in semi-arid lands, and methods for its control have been developed from fundamental investigations of the physical and chemical conditions of soils. The improvement of eroded land provides the soil scientists with special problems, and on this point papers were read dealing with wind and water erosion and its control in Europe and in North and South America. Other topics in this Commission were the reclamation of saline and alkaline soils under irrigated and non-irrigated conditions; factors regarding the time and amount of irrigation water; and the influence of tillage depth and fertilizer placement on plant rooting.

Delegates to Commission 7 (Soil Mineralogy) were especially concerned with the genesis and changes that occur in the minerals present in soils; methods of identification of these minerals and research techniques were discussed. Clay mineralogy was extensively dealt with especially from the point of view of the influence of clay minerals on the structure of soils and their chemical and physical properties. Papers were also included on clay migration and the specificity of clay minerals to certain types of soil-forming processes.

Particular interest was stimulated by the general sessions of the Congress when a number of invited lectures were given. The session on the World Soil Map has already been mentioned; other topics were: "The Dynamics of Water in Soils and Plants", by M. B. Russell; "New Methods of Research in Soil Science", by J. J. Fripiat; "Some Aspects of Nitrogen Metabolism in Soils", by G. W. Harmsen; "Tropical Soils", by G. Aubert; and a paper on "The Modern Dokuchaev Approach to Soil Classification" was read on behalf of I. P. Gerassimov, who was unfortunately unable to be present at the Congress.

Three symposia were held outside the scope of the Commissions: these dealt with the fertility of forest soils. the interaction of photosynthesis and mineral nutrition of plants, and metabolism of the primary assimilation of nutritive elements in the absorbent zone of roots.

For the energetic there was the choice of one of three tours, before or after the Congress. These proved extremely successful and were arranged to demonstrate the soils of south-east, east and north-east, and central and west Romania. For the not-so-energetic, profiles of all the major soil groups found in Romania were assembled in a magnificent display which was on view throughout the Congress. The All-Union Soil Science Society of the U.S.S.R. also organized an excursion from Moscow to Kherson, illustrating the soils of European Russia, and providing many interesting comparisons with similar soils on the plains of Romania.

The soil scientists of Romania have achieved a great deal in recent years, and the results of their hard work were well shown in the excellent presentation of the soil landscape of their country during the Congress and its tours. All who attended the eighth International Congress of Soil Science will want to congratulate their Romanian hosts on the smooth way in which the Congress was run and to wish them success in their future work.

E. M. Bridges

USE OF FILMS IN RESEARCH AND TEACHING

A WORKING party, with Dr. W. L. Francis as chairman, formed by the Department of Scientific and Industrial Research in June 1960, following a meeting of those interested in scientific films from universities, industry and Government departments, has now reported on *The Film in Scientific Research**.

The working party was to consider what is needed, in terms of information, research and development, in the field of scientific film and the appropriate functions of a central organization for scientific cinematography. It decided to limit its report mainly to the needs of scientific ciné-photography and photography, and to the uses of research film in research and in advanced teaching. An enquiry made for the working party by Mr. G. E. D. Bouler-Carter of Production Engineering, Ltd., indicated

* Department of Scientific and Industrial Research. *The Film in Scientific Research: Report of a Working Party*. Pp. vi + 67. (London: Department of Scientific and Industrial Research, 1963.)

that existing arrangements for training scientists, technicians and managements in scientific photography are inadequate, and that the low pay offered to scientific and medical photographers does not encourage pursuit of these occupations. Research workers have difficulty in obtaining information which would assist them in applying photographic methods, but certain advisory technical and research facilities could usefully be provided to assist them. Facilities for research photography are unco-ordinated in many universities; there is also lack of co-ordination between users and producers of educational film for universities, and existing distribution facilities for research films are inadequate.

The working party surveyed the demand for research films and their availability, and the use and improvement of scientific photography in research in Britain, as well as its use overseas. Recommendations were adopted proposing the establishment of an information service, preferably in some Government research establishment. The establishment was suggested of a central research photography unit, incorporating the information centre and financed jointly by Government and industry, the main function of which would be to conduct research on the techniques and development of scientific photography, and to encourage its use in industry and the universities. This it would do by rendering technical assistance and consultancy services where these are not readily available. Besides the establishment of a department of scientific photography in a suitable university or college of advanced technology, short advanced courses in scientific photography should be instituted in such colleges, particularly directed to the needs of scientists in industry. Central photography units should be encouraged in universities and, with the help of these units, universities should form their own libraries of 'concept film' as an aid in advanced teaching. The working party considered that the Department of Scientific and Industrial Research should be invited to compile, primarily as an aid in locating research film, a directory of users of cinematography in research in Britain, based on information already collected. The possibilities of making or compiling a film or films illustrating the techniques and applications of scientific photography should also be looked into carefully.

The recommendations relating to a university department of scientific photography, central photography units in universities and a research film library fall within the terms of reference of a Joint Committee of the University Grants Committee, the Department of Education and Science and the Scottish Education Department. It was appointed in 1963 to survey the present use of audio-visual aids in teaching and research in the pure and applied sciences in higher education. It is not expected, therefore, that these particular recommendations will be implemented before that Committee reports in 1965.

OCEANOGRAPHY IN THE CARIBBEAN AND EASTERN ATLANTIC

NO. 2 of the first volume of the *Boletin* issued by the recently established Oceanographic Institute at the Universidad de Oriente, Cumana, Venezuela*, contains five papers, the high standard and choice of subject-matter of which promise well for the future of the subject, in an area where oceanography and the scientific approach to fisheries problems have hitherto received little attention; and that little mainly offshore work during long-range cruises by research ships from the United States and other countries, with all the unavoidable lack of seasonal coverage that this implies.

The emphasis has clearly been on filling the gaps in basic knowledge of the hydrology of the region, both seasonally and into the inshore areas where no extensive observations had hitherto been made; while on the biological side correlation between organic sedimentation and the hydrology of the bay most readily accessible from the new laboratory and the revision of the systematics of a group of fishes important to the local inshore fishery, with detailed description of their osteology, will both help to provide a basis for future research on obviously desirable lines.

For these reasons it would seem that the director of the new institute deserves congratulations on his choice of studies to be encouraged, no less than the individual researchers on the high standard of presentation of their observations. Apart from their local significance the hydrological papers contain much of interest to oceanographers generally.

In the first paper, Herman G. Gade describes oceanographic observations in the south-eastern Caribbean Sea and adjacent Atlantic waters with special reference to the influence of the Orinoco River. Two cruises carried out in August 1960 and April 1961 by the R.V. *Guaiqueri* give adequate coverage for the region northwards from the delta, with a special investigation of the shallow Gulf of Paria between Trinidad and the mainland, and "round the corner" into the Caribbean.

There was great seasonal fluctuation in the volume of the upper water of the region. In the Atlantic the depth of the transition zone varied from 100 m in August to 160 m in April. The offshore surface water changed from less than 34 ‰ to more than 36 ‰ salinity during the same period. The slope of the isopycnals indicated moderate upwelling towards the coast in both Atlantic and Caribbean regions. This was considered to be a result of strong currents parallel to the coast, and was most intense during the dry season. There were indications of a counter current below and within the transition zone in both regions. This seems analogous to the similar effect suspected (though not yet proved) to exist below the upwelling zone in the Benguela current[1]. Here, the maintenance of the sub-surface salinity maximum is attributed to this feature. The negative anomaly of surface temperature in the coastal upwelling zone of the Caribbean region reached as much as 5° C in the dry season. The ocean current entering the Caribbean through Tobago Sound appeared as a strong jet affecting conditions as far west as Curaçao.

Within the Gulf of Paria a western region of low salinity was separate from a region of more oceanic water to the east. The eastern and central waters of the Gulf appeared to be rotating clock-wise. In the north, three layers of water were distinguished: the two upper ones of Gulf water, the lower one of Caribbean origin. While the residual current flows through the Gulf from south to north, Caribbean water may at times penetrate into it at all levels under the influence of tidal currents, but chiefly below the surface layer through the Dragon's Mouth. In the appendix the strength of the anticyclonic circulation in the gulf is discussed on the basis of the deformation of the sub-surface isopycnals. In the theoretical model the water rotates as a rigid body. Applied to the observed

* *Boletin del Instituto Oceanografico*, Volumen 1, Numero 2. Pp. 287–482. Suscripcion: Bs. 10 por volumen de dos numeros; Bs. 6 por numero suelto. (Cumana, Venezuela: Universidad de Oriente, Instituto Oceanografico, 1961.)

data, the corresponding angular velocity was found to be 0·17 radians/h.

The fresh-water discharge from the Orinoco and other Guiana rivers is carried by the ocean current some distance offshore. To the north of Venezuela it is displaced to the north of the upwelling zone and is not found along the coast. It follows the ocean current from Tobago Sound in a west-north-west direction and flows like a river into the central southern parts of the Caribbean Sea. This system appears quite stable except perhaps in September/October when slackening of the trade wind greatly reduces the coastal upwelling.

The Amazon discharge culminates in July and is carried by the Guiana current into the Caribbean, but is sometimes separated from the Orinoco water by a band of higher salinity. The bulk of the tropical low-salinity water (greatly augmented by precipitation at sea, in addition to the effects of Amazon discharge) enters the Caribbean north of 12° N.

Towards the end of the year the Amazon discharge is scarcely detectable in the Atlantic, and the Orinoco discharge becomes the main source of reduced salinities in the south-eastern Caribbean, its effects being limited to the south by the coastal upwelling and to the north by Atlantic water of the main Caribbean current.

In the next paper K. Kato discusses the relationships between organic sedimentation in Mochima Bay and the hydrological conditions. The sediment samples from 35 stations were collected by Dr. Roa Morales in October, and hydrological observations were made in November 1960.

The bay is a small narrow inlet on the East Coast of Venezuela opening into the Caribbean, some 8 km long north and south, and 2·3 km wide (not 23 km as printed). In contrast to conditions in the Gulf of Cariaco, where the prevailing easterly wind carries out the surface waters, setting up a fairly constant circulation as they are replaced by sub-surface movements, the waters of Mochima Bay, surrounded by mountains and with its opening to the north, are little influenced by winds. Here, water transport seems to be mainly due to tidal motion.

On the basis of organic carbon content, the bay was divisible into four sub-areas: (1) The entrance to Punta Garrapata, where the sediments were very poor in organic carbon, $< 0{\cdot}25$ per cent. (2) The narrow channel with carbon content still low, $< 0{\cdot}5$ per cent, but rising near shore to < 1 per cent. (3) The north-eastern part of the interior, carbon content still mainly < 1 per cent. (4) The south-western head of the bay, where there was abundant accumulation of organic matter, more than 6 per cent organic carbon at some stations, with average values of 2·8 per cent. Here also the *p*H value of the mud was appreciably lower than in the other sub-areas.

The attempt to determine possible relations between this disposition of organic sedimentation and the hydrobiological régime involved hydrological and chemical observations carried out at five stations, one to give the conditions in the Caribbean coastal water outside the bay, and one in each of the four sub-areas. Temperature, density, salinity, dissolved oxygen, nitrate, nitrite, phosphate and silicate were determined, following standard methods established by the Japanese Society of Oceanography. The results are described in detail with good graphic presentation.

There were temperatures of 24°–25° C in the upper 5 m of the bay water, where the stability was very high. Subsurface water from the outer Caribbean penetrated below the well-defined discontinuity layer at the flood tide and reached the bottom of the bay about the seaward boundary of the innermost sub-area. Here it came in contact with the interior bay water and this border (or slant plane) extended obliquely towards the surface seawards, nearing the surface in the narrow channel. It is held that appreciable turbulence may develop along the border where there is said to be much biological activity. A most vigorous growth of phytoplankton is said to occur here, but turbulence seems sufficient to prevent oxygen depletion, with comparatively rapid re-cycling of organic constituents and hence comparatively high *p*H values in the bottom muds.

The more stagnant water at the head of the bay seems isolated from the inflowing water. It contained abundant nutrients and a vigorous phytoplankton development in the surface layer, thought to be distinct from the dense population found in the channel area, with super-saturation of oxygen. The bottom water in this interior sub-area, however, showed oxygen depletion, and here there was an abundant accumulation of organic matter, as much as 1·3–6·5 per cent in organic carbon content.

A direct plankton investigation comparing the populations in the two distinct areas of high productivity should not be too difficult, and would go far towards confirming the general picture. This seems exceptionally clear and well presented. No doubt complexities would obtrude if a whole seasonal cycle were investigated, but the prime consideration of the bottom deposits, which might be termed a semi-conservative element, seems to have ensured that the summation effect is fairly represented; that the investigator has, in fact, allowed Nature to do some of his integration for him.

The third paper, by Herman G. Gade, describes the hydrographic observations during January–May 1961, carried out in continuation of his earlier work in the Gulf of Cariaco, and discusses the circulation and water exchange conditions they reveal. The Gulf of Cariaco is a much larger inlet than Mochima Bay, lying south of the Peninsula de Praya with its long axis east and west, and opening to the west. Thus the horizontal shear set up by the prevailing dry-season winds becomes the prime factor in maintaining the circulation within the Gulf. The inflow during these months is derived from the salinity maximum layer and below. Upwelling takes place fairly regularly within the Gulf, but is normally limited to water above 50 m. Below this the water exchange is slow except for a period during the dry season when the external water is heavier and the deeper layers participate in the exchange. Outflow is general above 25 m, and there is a compensation current below that depth. The repeated observations showed that the maximum period of deep upwelling fell earlier than during the 1960 season. This was thought to be connected with variations in the more general upwelling along the northern coast of Venezuela and, consequently, in the thickness of the upper water layer.

There seemed to be an almost permanent circulation of the upper layers inside the Gulf maintained by the wind shear, and this was verified by many drift measurements with current crosses, while the vertical circulation was studied directly by observations with Ekman current meters, in addition to the sections showing isohalines, isopycnals and oxygen isopleths, to obtain what is believed to be a typical profile of the vertical current distribution near the mouth of the Gulf.

The total flushing period of the Gulf was estimated to be 20 days, but in periods when the exchange is limited to higher levels the period would be shorter. The upper layers are much warmer than can be accounted for by the incoming radiation alone, and their salinity also is sometimes higher than the surface evaporation alone could account for. It is suggested that this is due to occasional reversal of the circulation during periods of calm or westerly winds, when the upwelling process must be slowed or stopped. This would be a direct analogy with the larger-scale anomalies that affect the normal régime of upwelling off the western coasts of the continents at times when the wind conditions become atypical[1].

A most detailed description of the osteological characters of eight species of Pomadasyidae is presented by Francis Mago Leccia in the fourth paper. The work was carried out with the definite objective of providing a sound systematic basis for future bionomic research on this family of

Perciforme fishes, known locally as *corocoros*. To further that end the paper is well and copiously illustrated, and convenient tabulations of the characters deemed taxonomically significant are provided. The importance of the group to the local fishery is shown by the fact, mentioned in the introduction, that already by 1959 more than 200 tons of them were being marketed annually.

The illustrations bring out clearly one point, not specifically dealt with by the author, but which is still likely to prove important in any future population studies on the group: whereas the otoliths look unpromising material for age-determinations, some of the other bones provide clear indications of growth zones, notably the supra-occipital crest of *Haemulon plumieri* and several of the opercular bones of *Orthopristis ruber*. Apart from their value in dealing with some fresh-water fishes, exemplified by Le Cren's[2] investigations of perch in Lake Windermere, the use of bones other than otoliths has been found useful in studying the growth of several very diverse species of marine fishes (see Menon[3,4] and Chang[5]).

This number of the *Boletin* is concluded by a short systematic paper by R. A. Curra of the new Institute, and P. de Miranda Ribeiro of the National Museum of Brazil (a pioneer in several lines of aquatic biology in Latin America). This seeks to establish the taxonomic position of a rare species of gymnotid fish first described by the latter in 1920, *Urumara rondoni* Miranda Ribeiro. To further this end, the main diagnostic characters of the three genera at present included in the family Rhamphichthyidae are illustrated and a formal key is provided.

EQUATORIAL UNDERCURRENT IN THE WESTERN INDIAN OCEAN

By Dr. J. C. SWALLOW,
R.R.S. *Discovery*, c/o General Post Office, London

FOUR times during March–June this year, the equatorial undercurrent has been observed by the R.R.S. *Discovery* in the course of its participation in the International Indian Ocean Expedition. We have found much higher speeds than those reported by Knauss and Taft[1] in the same season of the previous year, and a brief preliminary account may be of interest although not all the results have yet been processed.

Knauss and Taft found only a weak undercurrent in the western Indian Ocean, with maximum speeds generally less than 50 cm/sec and sometimes scarcely any significant eastward flow at all. In contrast, two of our sections showed speeds exceeding 120 cm/sec, comparable with those found in the Pacific undercurrent, and some subsurface eastward movement was always found.

On the first three crossings of the equator, a buoy was anchored at each of the stations shown (Figs. 1–3). Water movement relative to the ship was measured with direct-reading current-meters[2] and the ship's drift was determined by radar relative to the anchored buoy. Drogues were also used for measuring the near-surface current.

Section 1, 58° *E.*, *March* 18–23, 1964. The undercurrent was centred on the equator, with a maximum eastward speed of 122 cm/sec at 75 m depth, in the thermocline. The meridional component there was 28 cm/sec southward. The eastward speed falls to about half-value at 1° N. and 1° S. and meridional flow in the undercurrent was relatively weak at all stations. Spreading of the thermocline was only slight, the separation of the 15° C and 25° C isotherms being 105 m at the equator, and 80–95 m at 2° S. and 2° N. The water in the undercurrent had a high salinity, the maximum values decreasing from north to south. At the equator the maximum was 35·55 parts per thousand at 100 m, slightly deeper than the high-speed core. Surface currents were north-west, 30–60 cm/sec, at 1° N., the equator and 1° S., and south-west, 50 cm/sec, at 2½° S.

This section would be very similar to typical Pacific sections but for the asymmetry due to the deeper eastward flow at the southern end of the section.

Evidence in support of the persistence in time, and continuity with longitude, of the undercurrent comes

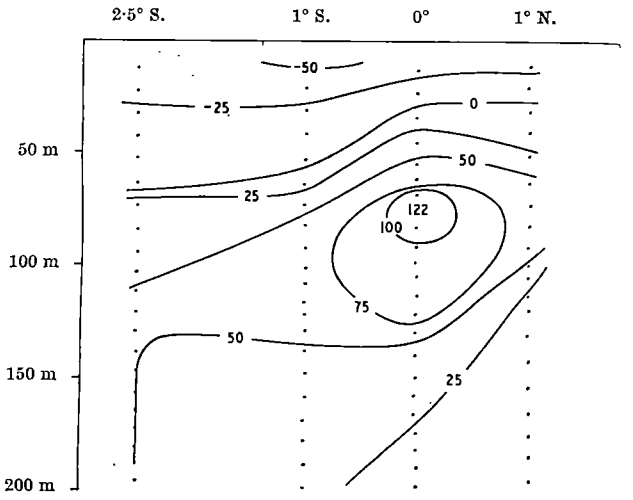

Fig. 1. Section 1, 58° E. March 18–23, 1964. Eastward component of velocity in cm/sec

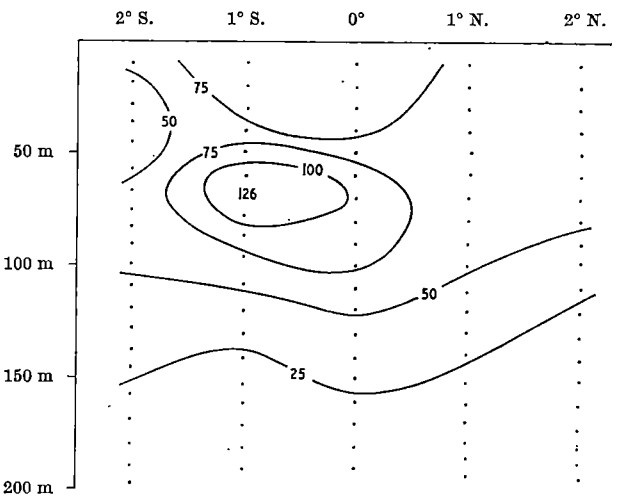

Fig. 2. Section 2, 67° 30′ E. April 26–May 1, 1964. Eastward component of velocity in cm/sec

from an observation made 2 weeks after this section was completed, by H.M.S. *Owen*[3]. At an anchor station on the equator in 55° 40′ E. on April 7, 1964, an eastward current of 90 cm/sec was found at a depth of 50 fathoms (91 m) with much weaker currents above and below.

Section 2, 67° 30′ *E., April* 26–*May* 1, 1964. On this section the surface currents were eastward, with speeds of about 90 cm/sec and meridional components converging on the equator. At the equator and 1° S. there was a significant subsurface maximum of eastward flow, reaching 126 cm/sec at 70 m depth at 1° S. The meridional components of this subsurface current were weak, with a tendency to diverge from the equator, and again there was a salinity maximum slightly deeper than the high-velocity core, decreasing in strength from north to south. It had a value of 35·42 parts per thousand at 92 m at the equator. The steepest part of the thermocline was deeper than the velocity maximum which lay between the 28° C and 29° C isotherms. There was a distinct spreading of the thermocline on this section, the separation of the 25° C and 15° C isotherms being 85 m at the equator, and only 53 m and 44 m at 2° N. and 2° S. Some indication of possible instability comes from one of the repeat observations at 2° S.; there appeared to be an eastward surge which would increase the speeds shown at that station by 30 cm/sec, exaggerating even more the asymmetry about the equator.

Section 3, 58° *E., June* 2–7, 1964. The undercurrent was still present, though weaker and shallower and displaced still farther south from the equator. The maximum eastward speed observed was 84 cm/sec at 39 m at 2° S. Surface currents had only weak zonal components and tended to diverge from the equator, being north-east at 2° N. and south-east to south at 1° S. to 3° S., 30–60 cm/sec. At the equator and 1° N. there was a weak westward surface current.

In the high-speed core, meridional components were northward, with a maximum of 49 cm/sec associated with the 84 cm/sec eastward maximum, but below that, between the 50 cm/sec and 25 cm/sec isotachs, the meridional flow was southward. The salinity maxima lay close to this lower zone, with a value of 35·30 parts per thousand at 79 m at the equator, and the steepest part of the thermocline was at about the same depth. There was no significant spreading of the thermocline, with the 25° C and 15° C isotherms varying between 75 m and 90 m separation throughout the section.

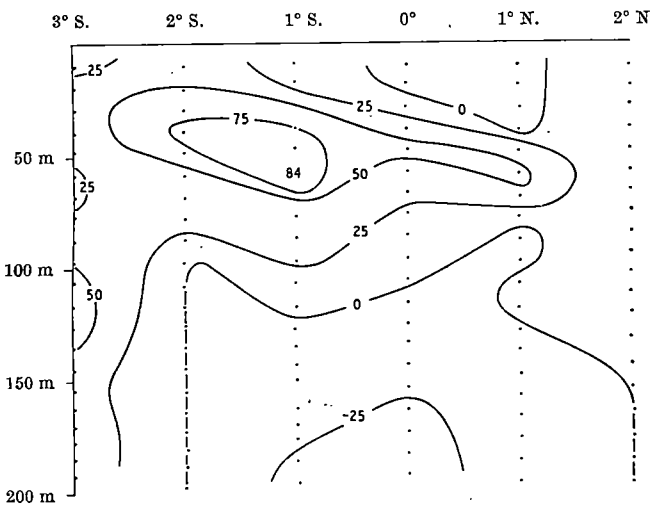

Fig. 3. Section 3, 58° E. June 2–7, 1964. Eastward component of velocity in cm/sec

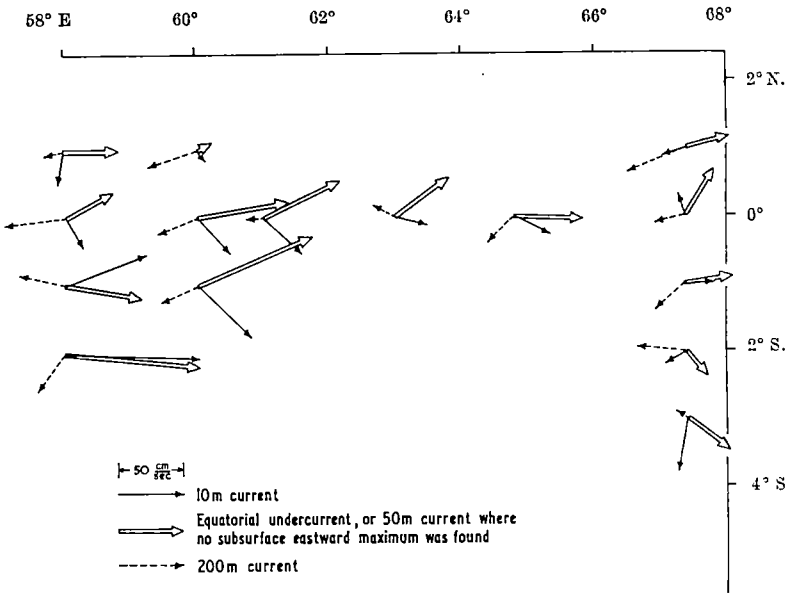

Fig. 4. Current vectors using mean of observations at 500–1,500 m depth as reference value. Lengths of arrows indicate speed. Examples shown represent 50 cm/sec. June 13–21, 1964

On our fourth visit to the equator, during June 13–21, 1964, short sections were worked in 58° E., 60° E. and 67½° E. with stations along the equator between the latter two. It seems more convenient to present these observations in plan view instead of vertical profiles. Time did not permit anchoring buoys; instead, at each station the usual current-shear measurements to 200 m were supplemented by observations at a few depths to 1,500 m using a telemetering current-meter provided by the Chr. Michelsen Institute and the Geophysical Institute, Bergen. The mean shear between 10 m and 500–1,500 m depths has been taken as representing the near-surface current, to which the upper part of the shear profile has been fitted. In Fig. 4, current vectors derived in this way are shown for each station at 10 m and 200 m depths, and in the sub-surface eastward maximum, which is generally near 50 m depth. Where no subsurface maximum was found, the 50 m value has been plotted.

Conditions at 58° E. and 60° E. were not very different from those in section 3, surveyed two weeks previously. The undercurrent appeared to slow down towards the east, but this could equally well be a time change. The salinity maxima and thermocline were again found a little deeper than the eastward velocity maxima, as in section 3, and there was little or no evidence of thermocline spreading.

Evidently, comparing these observations with those of Knauss and Taft, the equatorial undercurrent in the western Indian Ocean undergoes more complicated fluctuations than simple seasonal ones. It is hoped that it may be possible to relate these fluctuations to differences in the winds in the two years.

The work of the R.R.S. *Discovery* described here was carried out by the National Institute of Oceanography as part of the U.K. contribution to the International Indian Ocean Expedition. I thank Commander D. W. Haslam, R.N., in command of H.M.S. *Owen*, and also the Hydrographer of the Navy for permission to refer to H.M.S. *Owen's* results in advance of publication.

SMALL-SCALE IRREGULARITIES OF THE RADIO REFRACTIVE INDEX OF THE TROPOSPHERE

By J. A. LANE

Department of Scientific and Industrial Research, Radio Research Station, Slough

IN research on wave propagation through the troposphere at very high frequencies it is important to know the magnitude of the differences in refractive index which can occur over distances of a few centimetres or a few metres. This information is required both in investigations of propagation to points beyond the normal horizon and in studies of radar echoes observed in the absence of aircraft, clouds or precipitation (so-called 'angel' echoes). Experiments to measure these small-scale differences are in progress at the Radio Research Station, and it is the purpose of this article to summarize some of the first results obtained, using a balloon-borne, spaced-cavity, microwave refractometer. These results show much larger differences of refractive index than might have been expected on the basis of some earlier investigations of tropospheric structure carried out by other workers.

Microwave refractometers installed in aircraft have been used for several years in measurements of irregularities of the refractive index. A difficulty arises in this technique, however, because of the ambiguity resulting from the horizontal component of the motion of the aircraft, in the measurement of vertical gradients. This problem is largely avoided in soundings with captive balloons. The Radio Research Station refractometer uses three cavities in a two-channel, differential system. The cavities are connected in two pairs, and with each pair a measurement is made of the difference in the refractive index of the air in the cavities. This information, together with measurements of pressure and wind speed, can be telemetered to a ground station and recorded as the balloon ascends and descends. Possible applications of the spaced-cavity system are shown in Table 1, cavity *A* being compared with each of the others.

Table 1. Applications of Spaced-cavity Refractometer

Arrangement	Location of cavities		Quantities measured
I	o *C* o *B* o *A*	*A*, *B* and *C* all open	Vertical differences (*A*–*B*, *A*–*C*)
II	o o o *A* *B* *C*	ditto	Horizontal differences (*A*–*B*, *A*–*C*)
III	o o *A* *B* o *C*	ditto	Simultaneous vertical and horizontal differences (*A*–*B*, *A*–*C*)
IV	*A* *B* o o *C*	*A* and *C* open, *B* closed	Total mean square fluctuation, *A*–*B*, and vertical difference, *A*–*C*

Adjacent cavities can be located, in any of the four arrangements, at spacings of 0·1–1 m if required. A vertical spacing of 1 m selects those irregularities which would be important in forward scatter at, for example, a wave-length of 3 cm on a path 300 km long. The first experiments indicated the need for a high sensitivity in the refractometer and in the model now in use the residual noise-level is equivalent to fluctuations of less than 0·1 *N* unit. ($N = (n-1)10^6$, where n is the refractive index.) The investigations in progress are primarily intended to measure the small-scale differences in and near elevated isothermal and inversion layers in conjunction with vertical-incidence radar soundings[1,2]. Early theories of 'scatter' propagation did not consider the possible influence of thermal stability in the intensity and scale size of refractive-index irregularities, but more recent work[3–5] has emphasized its importance. However, no detailed measurements over distances of 1 m and less have hitherto been made. In the Radio Research Station experiments carried out so far, most soundings have been made with arrangement III of Table 1 (with spacings *A*–*B* and *A*–*C* of 1 m), for this gives a direct indication of anisotropic structure. A few trials, however, have been made with arrangements I and IV. Some selected results are summarized in the following discussion. The measurements described were all made at Cardington, Bedfordshire, at the Royal Air Force Balloon Unit.

On May 28, 1964, a sounding was made at 13.00 h G.M.T., immediately following a routine sonde ascent by a captive balloon at 12.00 h G.M.T. Conditions were clear but not anticyclonic. The sonde data showed an inversion layer in which the temperature increased by 1·5° C between heights of 0·43 and 0·50 km. Light winds (1·5–2 m/sec) prevailed throughout the soundings. Between the inversion and the ground the mean vertical gradient of temperature was about − 9° C/km (that is, the dry adiabatic value). The refractometer was equipped with three open cavities in arrangement III of Table 1. The peak and mean square values, ΔN (peak) and $\overline{\Delta N^2}$, measured at various heights are shown in Table 2, each entry being derived from 50 sample readings of the paper-chart record obtained from the telemetry receiver.

Table 2. Variation of Small-scale Differences of Refractive Index with Height through an Inversion Layer

Clear conditions: Cardington, Bedfordshire, May 28, 1964. Cavity arrangement III (Table 1)

Height (km)	Pair *A*–*B* spacing 1 m		Pair *A*–*C* spacing 1 m		Remarks
	ΔN (peak)	$\overline{\Delta N^2}$	ΔN (peak)	$\overline{\Delta N^2}$	
0·15	2·0	0·35	2·0	0·35	2-min sample: refractometer stationary
0·43–0·45	3·0	1·0	2·5	0·9	1-min sample: refractometer ascending through base of inversion
0·46	1·5	0·3	1·5	0·3	2-min sample: refractometer stationary
0·49	2·0	0·2	1·5	0·3	ditto
0·52	1·5	0·2	1·5	0·35	ditto

The largest values of ΔN (peak) and $\overline{\Delta N^2}$ were measured in the first 20 m above the base of the inversion. However, it is of interest to note that on this occasion the values of ΔN (peak), over a 1-m spacing, were almost as large in the unstable air at a height of 0·15 km as in the inversion. Values of $\overline{\Delta N^2}$, obtained from each pair of cavities over periods of the order of a few tens of seconds or more, did not indicate any marked anisotropic effects in distances of 1 m on this sounding.

Another measurement, using the same arrangement of open cavities, was made through an elevated inversion layer on the morning of May 29, 1964, at 09.30 h G.M.T. Conditions became clear during the ascent, after morning mist. Fig. 1 shows the results of this sounding, together with the coarse variation of refractive index and temperature with height obtained from the routine sonde ascents at 12.00 h G.M.T. The sonde ascent showed a maximum in the vertical gradient of refractive index in a layer between heights of 0·37 and 0·52 km. The largest differences of refractive index, over distances of 1 m in the horizontal and vertical directions, were 4–5 *N* units and were observed at a height of 0·37 km. The anemometer on the refractometer indicated a minimum value of wind speed at a height of 0·37 km.

In later experiments even larger differences in refractive index (over a 1-m spacing) were measured in elevated

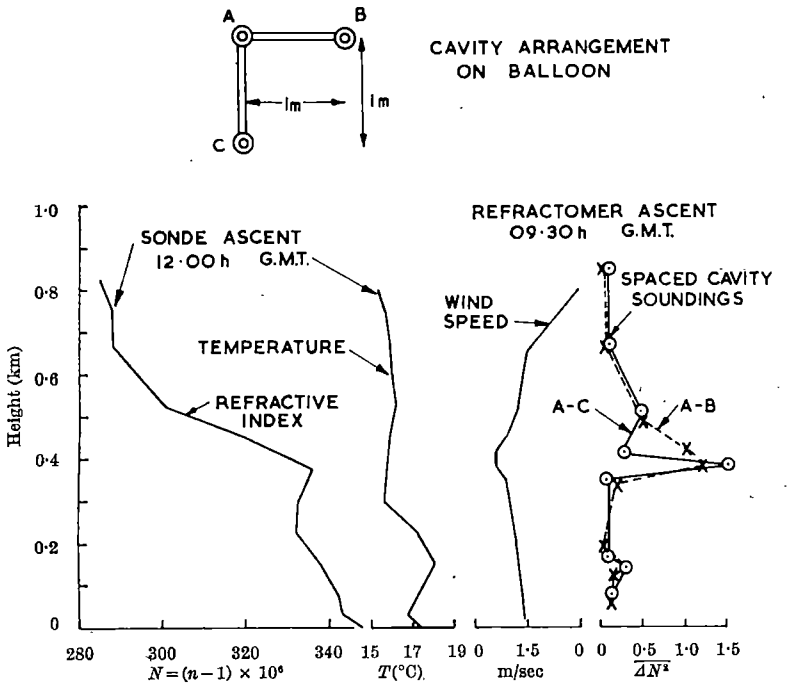

Fig. 1. Results of captive-balloon soundings; Cardington, Bedfordshire, May 29, 1964. ○ and × show the mean square variation, $\overline{\Delta N^2}$, in a 3-min sample at the heights indicated

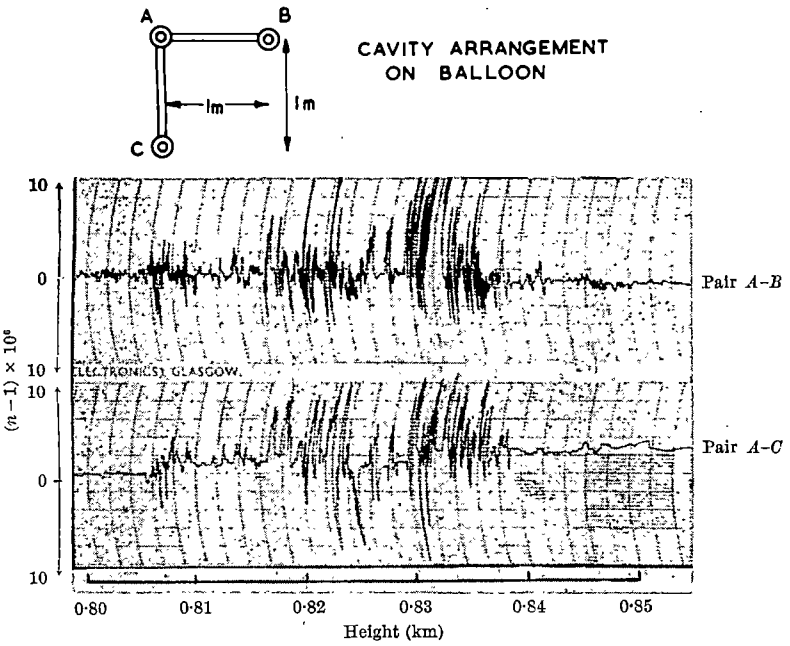

Fig. 2. Results from spaced-cavity refractometer; Cardington, Bedfordshire. 13.30 h G.M.T., July 27, 1964, height range 0·80–0·85 km

isothermal or inversion layers, in conditions which were fine but not always anticyclonic. An example of such a layer is shown in Fig. 2. Several differences of 10 N units were measured in both the horizontal and vertical directions as the refractometer ascended from 0·81 to 0·84 km. The sounding was made on July 27, 1964, at 13.30 h G.M.T., in fine conditions after morning rain, and it provides an interesting example of a well-defined layer which was not associated with anticyclonic subsidence.

One sounding, made with arrangement IV (Table 1) in anticyclonic conditions on July 1, 1964, gave results which indicated that in stable layers the scale size of the irregularities is considerably less than the value of 100 m assumed in theories of tropospheric scatter. As the refractometer moved into the layer, fluctuations of about 10 N units on the chart record obtained from the open cavities, A–C (1 m apart), were accompanied by fluctuations of 15 N units in the record from the open–closed pair, A–B. A large fraction of the intensity or total mean square fluctuation at the base of the layer was contained therefore in those irregularities extending over distances of 1 m or less.

On August 20, 1964, a first trial was made to investigate the presence of marked differences of refractive index over vertical distances less than 1 m. Two cavities were located 12 cm apart in the vertical direction and a sounding made in conditions which were fine but not anticyclonic, with patches of cloud at a height of 1·1 km. Several examples were obtained, in clear air at heights between 0·6 and 1·3 km, showing differences of 2–3 N units over the 12 cm spacing. This distance is believed to be the smallest over which a direct measurement of refractive-index difference has been made in the lower atmosphere.

Finally, it is of interest to compare the data from the spaced-cavity soundings with some previous published measurements of refractive-index irregularities. Flights made in earlier Radio Research Station work with a refractometer in an aircraft have indicated that changes of 10–20 N units can occur in a vertical distance of approximately 1 or 2 m in subsidence inversions, but precise measurements of these small-scale irregularities are difficult in soundings with aircraft for the reasons given earlier in this article. From the results of a few flights with a refractometer in an aircraft over Washington, D.C., Bussey and Birnbaum[6] deduced that, except in or near clouds, differences over horizontal distances of 0·5–5 m had amplitudes of less than 0·04 N units, that is, two orders of magnitude less than the values obtained for a 1 m spacing in some of the Radio Research Station measurements. Straiton, Deam and Walker[7] determined the mean square fluctuation, $\overline{\Delta N^2}$, in distances of 5 m and less, also from soundings using an aircraft: they obtained a maximum value of $\overline{\Delta N^2} = 5 \times 10^{-2}$ in a horizontal flight at a height of about 1 km. This value is 25–30 times smaller than the maximum measured in the sounding illustrated in Fig. 1. In measurements with a balloon-borne, capacitor-type refractometer ascending at 300 m/min, Turner and Hay[8] noted irregularities of the order of 1 N unit in a vertical distance of about 10 cm, but their soundings were limited to the first 60 m above ground.

We conclude from these initial experiments with a spaced-cavity refractometer that instantaneous differences of refractive index of a few N units over distances of 0·1–1 m can exist in summer conditions in England in the first 2 km or so above ground, even in unstable air. Larger differences (about 10 N units) have been observed in several elevated layers in which the temperature was uniform, or increased by 1°–2° C, over vertical distances of the order of 100 m. The measurements also indicate that in stable air the scale size of the irregularities is of the order of a few metres. However, further measurements are desirable in elevated layers of greater thermal

stability than those investigated in the experiments described.

The work described was carried out as part of the programme of the Radio Research Board, and this article is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research. The balloon soundings were carried out with the co-operation of the Meteorological Office, the Royal Air Force Balloon Unit, and the Ministry of Aviation. The initial experimental work was carried out by Mr. D. S. Froome. The latest model of the refractometer and the telemetry equipment were developed by Mr. C. S. Fowler. Mr. M. P. M. Hall assisted in the design of the microwave equipment.

VERTICAL DISTRIBUTION OF RADIONUCLIDES AS MEASURED IN OCEANIC ANIMALS

By Prof. WILLIAM G. PEARCY and CHARLES L. OSTERBERG
Department of Oceanography, Oregon State University, Corvallis

THE north-east Pacific Ocean contains two sources of artificial radionuclides: neutron-induced isotopes from the Hanford nuclear reactors on the Columbia River and fission products (fall-out) from weapons tests. Zinc-65 is one of the principal radionuclides in nearshore waters off Oregon. Although it is often a component of fall-out, most of the zinc-65 off Oregon arises from Hanford operations[1]. A number of fall-out radionuclides were also present in measurable amounts before the nuclear test ban became effective. Zirconium-95+niobium-95 and cerium-141-144 in particular have been reported in marine organisms[2,3]. This article is based on analyses of samples collected when both sources of radionuclides were present. Subsequent diminution of zirconium-95+niobium-95 through radioactive decay precludes repetition of these observations.

Animals were collected over a 24-h period on January 7–8, 1963, 50 miles off Newport, Oregon. An Isaacs–Kidd midwater trawl with a multiple plankton sampler as an opening–closing cod-end unit provided samples from three depth intervals: 0–150 m, 150–500 m, 500–1,000 m (ref. 4). Volume of water filtered was estimated from the cross-sectional area of the mouth of the trawl and distance towed at each depth interval, assuming 100 per cent filtration efficiency. A single mesh size (12 mm stretched measure) was used as a liner throughout the body of the trawl. Two tows during daylight and two after dark provided the material for radioanalysis.

Samples from each depth-interval, consisting of mixed species collections (mostly crustaceans, chætognaths and fishes), were drained to remove excess fluids (radioanalysis of this material showed that it contained only a minor fraction of the radioactivity), weighed (wet-preserved weight), ashed at 450° C, and packed into 15-c.c. plastic tubes. The samples were reweighed, and the tubes sealed. Samples were analysed in the well of a 5-in. × 5-in. Harshaw NaI(Tl) crystal used with an *ND* 130*AT* pulse-height analyser. Counting time was either 100 or 400 min, depending on sample activity. Counts were converted to picocuries per gram wet weight and per 1,000 m³ water filtered.

Zirconium-95+niobium-95 and zinc-65 activity of organisms from different depths is shown in Fig. 1. Levels of zirconium-95+niobium-95 per gram wet weight were always highest in animals from the surface layer (0–150 m), where activity averaged about nine times that in animals collected in deeper waters. Zinc-65/g was not higher in surface waters but appeared in rather uniform concentrations at all depths.

Presumably the difference in vertical distributions of the two radio-elements is related to how these elements are involved in biological processes. Zinc, a transition element, is a constituent of several enzymes. Zinc-65 is concentrated by many marine animals[3]. Zirconium and niobium apparently have relatively little biological significance in the sea. ^{95}Zr–^{95}Nb do not appear to be concentrated except by second trophic level animals, such as some copepods, euphausiids, pteropods, and salps[4]. Concentration is thought to occur through mechanical filtration of phytoplankton cells and other particulate material with which the radioactivity is probably associated. Zinc-65 and zirconium-95+niobium-95 also have different biological turn-over rates. Experiments by Chipman[5] show that, in general, fission products are poorly absorbed and are rapidly egested. Zinc-65, on the other hand, is retained over a longer period of time. This may explain why zinc-65/g is fairly constant in animals taken at all depths down to 1,000 m, whereas zirconium-95+niobium-95 are more restricted to surface waters (Fig. 1). Grazing by herbivores is normally confined to surface waters. Animals collected from greater depths, although having grazed in upper layers the previous night, could have lost most of the fission products through production of fæcal pellets[6].

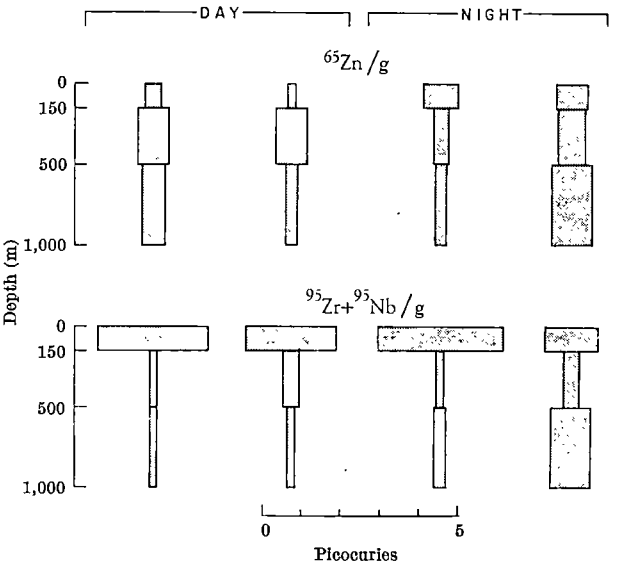

Fig. 1. Zinc-65 and zirconium-95+niobium-95/g/wet weight of pelagic animals collected from 0–150 m, 150–500 m and 500–1,000 m during day and night periods January 7–8, 1963, at 44° 40′ N., 125° 15′ W.

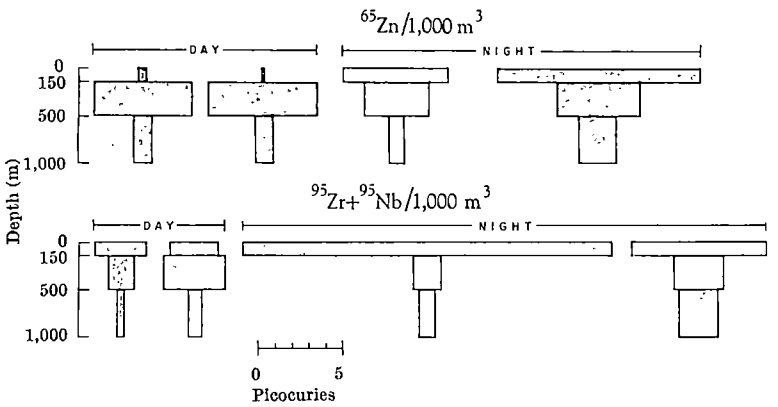

Fig. 2. Total zinc-65 and zirconium-95+niobium-95 activity in the animals filtered from 1,000 m³ of water at the three depth intervals during day and night periods

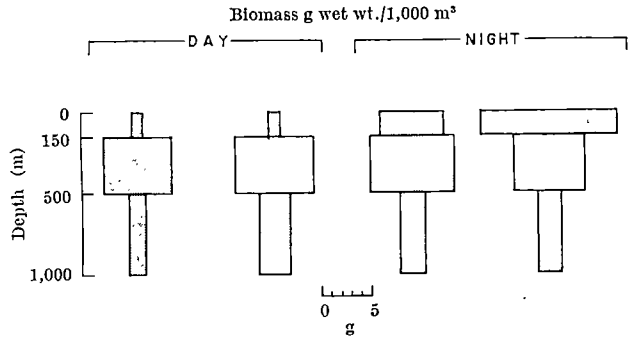

Fig. 3. Wet weight of pelagic animals per 1,000 m³ at the three depth intervals during day and night periods

Vertical distribution of zinc-65 and zirconium-95+niobium-95, as measured in animals collected at three depths, is a function of the biomass per 1,000 m³ of water and radioactivity/g (Fig. 2). Day–night differences in radioactivity occur, particularly in surface waters. Here, concentrations of both isotopes are lower during the daylight period than during darkness. After dark, activities are highest at the surface and are progressively lower at mid-depths and in deep water. During daylight, zinc-65 was highest at mid-depths and lower at the surface than at any other depths, but a similar increase of zirconium-95+niobium-95 at mid-depths during the day is not evident.

Explanations of these observed differences depend on a number of factors. Since biomass changes with time and depth, radioactivity/1,000 m³ of water might be expected to vary accordingly. A rather close correlation did exist between total zinc-65 and biomass (Figs. 2 and 3), indicating that zinc-65 was distributed quite uniformly among animals from the entire 1,000-m column. Histograms for zirconium-95+niobium-95 per 1,000 m³ (Fig. 2) are not similar to either those of biomass or radioactivity per gram. However, they must result from a combination of these two factors, since the values used in preparing Fig. 2 are products of those used in Figs. 1 and 3.

Day–night changes in the vertical distribution of radioactivity (Fig. 2) are correlated with the known diurnal vertical migrations of oceanic animals into surface waters at night. Although a night-time increase in biomass in surface waters is shown (Fig. 3), our results do not provide unequivocal evidence that vertical migrations caused these daily changes in radioactivity. Since both the total amount of radioactivity and the biomass in a column of water 1,000 m deep were larger for night collections than day collections, animals not sampled during the day may have merely avoided the net or migrated below the depth of sampling. That vertical migrations actually occur, however, is evidenced in other studies by the shift of peak catches of oceanic animals such as mesopelagic fishes from surface waters during the night to mid-depths during the day. The relatively high zinc-65 activity at mid-depths during the day and at the surface during the night can also be interpreted as evidence for such migrations (Fig. 1).

In summary, this work shows that radioactivity/g of oceanic animals may demonstrate different patterns of depth distribution for different radioisotopes. Moreover, since zinc-65 is ubiquitous in marine animals off Oregon, vertical migrations of biomass will result in a vertical flux of radiozinc. It is interesting that the largest day–night changes in zinc-65/1,000 m³ occurred across the depth of 150 m, a depth which corresponds approximately to the halocline and a rapid density change that impedes vertical mixing by physical processes in this portion of the Pacific Ocean. Further generalizations based on these limited data are obviously unwarranted, as little is known of temporal or spatial variations of these radionuclides associated with oceanic animals.

FOAM FRACTIONATION OF CATIONIC SURFACTANTS: EFFECT OF INORGANIC ACIDS AND BASES

By Prof. R. B. GRIEVES and D. BHATTACHARYYA
Illinois Institute of Technology, Chicago

FOAM fractionation has been utilized for the transfer of organic solutes which by themselves have little foaming ability, for the purification of surface-active agents, for the separation of enzymes, for the ion flotation of radioactive cations from waste streams, for the treatment of secondary sewage effluents to remove non-biodegradable organics, etc. A number of extensive reviews of the process have appeared in the literature[1–3]. Recently, several investigations have been made on the operating, systemic and geometric variables affecting the process. Grieves *et al.*[4–9] have determined the influence of surfactant, feed concentration, temperature, gas-rate, feed-rate, foam height, foam column diameter, liquid solution height, and feed position on the batch and continuous foam fractiona-

tion of anionic and cationic surfactants. Other investigations along these lines have been conducted by Brunner and Lemlich[10], by Kishimoto[11] and by Kevorkian[12].

The information available concerning the influence of strong inorganic electrolytes on the foam fractionation of surfactants from aqueous solution is very limited. Investigations[13,14] have shown that the isoelectric point is the optimum *p*H for foaming amino-acid and protein solutions. Sengupta and Pipes[15] have investigated the influence of a number of electrolytes on the continuous foam separation of alkyl benzene sulphonate, an anionic surfactant, while the influence of various salts on the foaminess of sodium lauryl sulphate solutions has been determined[16,17]. No work of this nature has been reported on cationic agents. The object of the work recorded here is the establishment of the effect of strong inorganic acids and bases on the batch foam fractionation of the ethylhexadecyldimethylammonium bromide–water system (EHDA-Br). The responses of the removal ratio and of the lesser coefficient of fractionation to varying concentrations of hydrochloric acid, sulphuric acid, sodium hydroxide and calcium hydroxide are presented together with comparison runs utilizing sodium chloride and sodium sulphate. The effects of sulphuric acid on an additional feed concentration of EHDA-Br and on a single feed concentration of hexadecylpyridinium chloride (HPy-Cl) are included.

All the experiments were carried out in a cylindrical column, 105 cm high and 10 cm diam., made of 'Lucite'. High-purity nitrogen was saturated with water, metered with a calibrated rotameter, and passed through twin, sintered glass diffusers of 50μ porosity. In each experiment, 2,000 ml. of the feed solution of EHDA-Br (together with an acid, base or salt) in distilled water were placed in the column. Nitrogen bubbles were dispersed through the solution for a period of 15 min with continuous foam removal at a port located 74·5 cm above the feed solution level. A feed concentration of 125 mg/l. EHDA-Br ($3{\cdot}30 \times 10^{-4}$ molar) was used in most of the experiments, employing a nitrogen rate of 3,700 ml./min (at 0° C and 1 atm.). Additional experiments utilized 87·5 mg/l. ($2{\cdot}31 \times 10^{-4}$ molar) feed solutions of EHDA-Br with a nitrogen rate of 4,950 ml./min and 113 mg/l. ($3{\cdot}30 \times 10^{-4}$ molar) feed solutions of HPy-Cl with a nitrogen rate of 3,700 ml./min. Prior to each run, carefully measured quantities of hydrochloric acid, sulphuric acid, sodium hydroxide, calcium hydroxide, sodium chloride or sodium sulphate were added to the surfactant feed solution, and the *p*H measured with a Beckman *p*H meter. The *p*H of the distilled water was 6·6 and the *p*H of pure 125 mg/l. EHDA-Br solutions was 6·1. This would seem to indicate that a small amount of hydrolysis of the quaternary ammonium ions occurred. Temperature was maintained at 31·5° C. At the termination of each experiment the residual solution volume was measured, and the concentration of surfactant was determined by a two-phase titration technique[18]. Random analyses of the collapsed foam were conducted for material balance verifications. The method of analysis was accurate to within ± 1·0 mg/l. The *p*H of the residual solution and the *p*H of the collapsed foam were measured.

Results of the experiments with 125 mg/l. feed solutions of EHDA-Br are presented in Figs. 1 and 2, in which the removal ratio, $V_f y_f / V_t x_t$, and the lesser coefficient of fractionation, x_r/x_t, are related to *p*H. V_f and V_t are the volumes (ml.) of the collapsed foam and feed solution, respectively, and y_f, x_r and x_t are the concentrations of EHDA-Br in the collapsed foam, residual solution, and feed solution, respectively. For maximum efficiency, it is desirable to minimize x_r/x_t while maintaining $V_f y_f / V_t x_t$ at a large value. Maximization of $V_f y_f / V_t x_t$ generally signifies an excessively large and dilute foam stream. For each experiment, the following material balances may be written:

$$V_t = V_r + V_f \qquad (1)$$

$$x_t V_t = x_r V_r + y_f V_f \qquad (2)$$

V_r is the volume (ml.) of the residual solution. V_t was held constant at 2,000 ml. For given x_t and V_t, y_f may be computed from experimental values of x_r and V_r, using equations (1) and (2).

From Fig. 1 it may be observed that the addition of sulphuric acid causes a rapid increase in the removal ratio, reaching a maximum at *p*H = 3·3 followed by a sharp decline. The behaviour with hydrochloric acid is similar except that the increase begins more slowly (as the *p*H is decreased from 6·1) and reaches a peak at *p*H = 2·7. The different behaviour of the two acids would be more pronounced if $p\mathrm{Cl}^-$ and $p\mathrm{SO}_4^{2-}$ were plotted on the abscissa instead of *p*H. In this case, the sulphuric acid curve would be shifted to 0·3 units to the *right* indicating a maximum in the removal ratio at $p\mathrm{SO}_4^{2-} = 3{\cdot}6$. The effect of the addition of strong bases on $V_f y_f / V_t x_t$ is not pronounced. For sodium hydroxide the removal ratio on the average is virtually identical to that of a pure EHDA-Br solution. For calcium hydroxide there appears to be a slight increase in the removal ratio as the *p*H is increased. The variation in the two points between *p*H = 7·0 and *p*H = 8·0 seems to be due to experimental scatter. For experiments with the *p*H of the feed solution

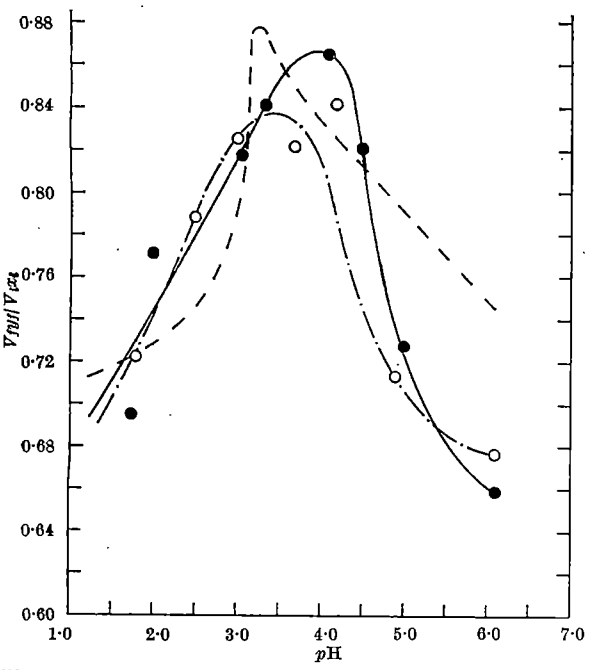

Fig. 3. Relationships between $Vfyf/ViXi$ and pH with sulphuric acid. ○—·—, HPy-Cl, 113 mg/l.; ●—, EHDA-Br, 87·5 mg/l.; ———, EHDA-Br, 125 mg/l.

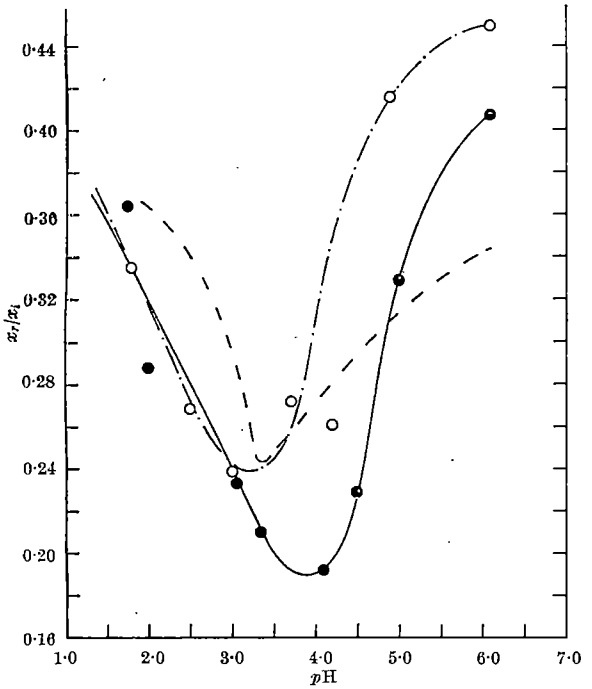

Fig. 4. Relationships between x_r/x_i and pH with sulphuric acid. Symbols as for Fig. 3

between 7·5 and 9·5, the pH of the residual solution and the pH of the collapsed foam were both lower than the feed. When the pH of the feed was between 6·1 and 7·0, the opposite tendency was observed. For all other feed pH values, no changes were noted. Part of the variation may have been due to the presence of low concentrations of carbon dioxide in the distilled water or to a slight amount of hydrolysis.

Fig. 2 indicates that the concentration of the residual solution, and thus the lesser coefficient of fractionation, behave analogously to the total removal at pH < 6·0. x_r/x_i passes through minima at virtually the same points where $V_f y_f / V_i x_i$ is maximized. Two investigations[5,7] have shown previously that when considering such operating variables as gas-rate and feed-rate, the residual concentration and removal ratio do not increase and decrease analogously. Considering values of x_r/x_i for pH > 7·0, no trend can be seen. Again the effect of pH variation on the basic side is small.

Figs. 3 and 4 present the effect of pH depression by sulphuric acid on the foam fractionation of 87·5 mg/l. EHDA-Br and of 113 mg/l. HPy-Cl solutions. The curves for 125 mg/l. EHDA-Br solutions are included for comparison. From Fig. 3 it should be noted that for the more dilute EHDA-Br solutions, a lower concentration of sulphuric acid is necessary to produce the maximum, and the effect of sulphuric acid on the removal ratio is more pronounced. The influence of sulphuric acid on HPy-Cl solutions is similar to that on EHDA-Br. The behaviour of the lesser coefficient is again analogous to that of the removal ratio. For 125 mg/l. EHDA-Br and 113 mg/l. HPy-Cl the minima are at approximately the same pH (3·2–3·3) and yield similar values of x_r/x_i at the minima (0·24–0·25). However, the shapes of the curves are quite different.

A few comparison runs were conducted with sodium chloride and sodium sulphate. Results of the experiments are presented in Table 1, together with values for hydrochloric acid and sulphuric acid (smoothed) at the same Cl^- and SO_4^{2-} concentrations. With both salts the same general trend may be observed as with the corresponding acids, with values of $V_f y_f / V_i x_i$ passing through maxima and values of x_r/x_i passing through minima. The maximum (and minimum) for sodium chloride is at a higher anion concentration than the maximum for sodium sulphate. Comparing the relative effects of H^+ and Na^+, the values of x_r/x_i for sodium sulphate and sulphuric acid are practically identical, while the removal ratio for sulphuric acid is greater at the two lower SO_4^{2-} concentrations and less at the highest concentration. The removal ratio behaves in a similar manner for sodium chloride and hydrochloric acid except that the differences are greater. In addition, there is a considerable difference in the values of x_r/x_i between the acid and the salt. A final comparison between the effects of various anions may be made by noting the experiments with sodium hydroxide listed in Table 1. Contrasted to Cl^- and SO_4^{2-}, the effect of OH^- is minimal.

Table 1. COMPARISONS BETWEEN SALTS, ACIDS, AND BASES FOR 125 MG/I. EHDA-Br SOLUTIONS

The separation obtained in a foam fractionation process depends on two interrelated factors: the tendency of the surfactant molecules to be adsorbed at the gas–liquid interfaces of the bubbles as they rise through the bulk solution; the stability (persistence) and drainage of the foam phase rising above the foam-solution interface. In a batch foaming process, in addition to the single transfer stage in the bulk solution multiple stages exist in the rising column of foam, and each cross-section of foam is enriched continually by the drainage of concentrated liquid from the foam layers above the particular cross-section. The bulk solution concentration, the concentration of surfactant in the surface layers at the gas interfaces in the foam, and the concentration of entrained (draining) liquid in the foam all continually change with time. At any time, the latter two concentrations vary with height in the rising column of foam.

Most of the effects which were observed may be explained on the basis of the anions (Cl^-, SO_4^{2-}) added to the surfactant solutions rather than on the basis of *p*H. Quaternary ammonium salts are almost completely dissociated in solution and only a slight amount of hydrolysis occurs to form quaternary ammonium bases. The adsorption of surfactant ions at a gas-liquid interface involves the formation of a diffuse, electrical double layer consisting of a unilayer of surfactant ions in the surface and a Gouy region below it which is poorer in solute. The resulting potential which is set up as soon as the first surfactant ions are adsorbed acts as an activation barrier, which is reduced by an increase in the ionic strength of the solution[19]. The decrease of the surface tension of surfactant solutions on the addition of salts validates this description[16,17,20]. In the case of cationic surfactants, the nature and valency of the anions are significant factors and the initial increase in $V_f y_f / V_i x_i$ and decrease in x_r/x_i as the *p*H is lowered below 6·1 may be explained by the greater adsorption of surfactant ions and the resulting more voluminous and stable foam. In this regard, SO_4^{2-} is more effective than Cl^-, while OH^- (*p*H elevated) has little influence. From Table 1 it may be observed that there is some difference between sodium sulphate and sulphuric acid and a significant difference between sodium chloride and hydrochloric acid, indicating that changes in cations do have some effect. Similar behaviour has been noted for anionic surfactants[21] and the hydrolysis of impurities may have brought it about. As the *p*H is lowered below the values (3·3 and 2·7) corresponding to the maxima and minima with sulphuric acid and hydrochloric acid, respectively, the decrease in $V_f y_f / V_i x_i$ and increase in x_r/x_i may have been caused by the promotion of foam drainage by the electrolytes present. Foam drainage increases as the electrolyte concentration is increased due to the ability of the liquid lamellæ to thin to a greater extent as the ionic concentration is raised[22]. It is possible that this effect was shielded by the increase in the adsorption of surfactant ions at higher values of *p*H (6·1 → 3·5); then as the *p*H was further lowered the increase in adsorption levelled off and the increased foam drainage due to the electrolyte became the significant factor. Maxima in relations between foam stability and electrolyte concentration have been observed previously for anionic surfactants[17,21].

This investigation was carried out under the sponsorship of the Commission on Environmental Hygiene of the Armed Forces Epidemiological Board and was supported in part by the U.S. Army Medical Research and Development Command, Department of the Army, under research contract *DA–49–193–MD–2629*.

A GAS-TIGHT GROWTH CHAMBER FOR INVESTIGATING GASEOUS NITROGEN CHANGES IN THE SOIL : PLANT : ATMOSPHERE SYSTEM

By P. J. ROSS, Dr. A. E. MARTIN and Dr. E. F. HENZELL

C.S.I.R.O. Divisions of Soils and Tropical Pastures, Cunningham Laboratory, St. Lucia, Queensland

LOSSES of nitrogen from the soil : plant system have never been measured directly, and gains have almost always been estimated from conventional nitrogen balance experiments. Quantitative knowledge of changes in nitrogen occurring in an enclosed atmosphere surrounding the system should not only allow satisfactory nitrogen balances to be struck, thus resolving Allison's[1] enigma, but also permit the kinetics of these changes to be studied, including the effects of such factors as temperature, soil moisture, and soil type. The use of nitrogen-15 would increase the power of such a technique; for example, by cross-labelling nitrogen fertilizer and nitrogen gas, it should be possible to identify simultaneous gains and losses instead of measuring net changes as has been invariably done in the past. This article describes a gas-tight assembly which has been successfully used in this laboratory for preliminary balance studies on normal soil : plant systems.

It is important to stress the need for a strictly closed system of small volume that will allow the prolonged growth of plants in soil under conditions as natural as possible. If the system is not strictly closed, changes due to leakage may result, especially over long periods; a large volume (relative to the size of the plants) makes the detection of small changes difficult, and abnormal or restricted conditions limit the applicability of the results obtained. Systems used by previous workers, though adequate for particular purposes, are thus defective from this point of view. For example, closed systems have been used for studies of gaseous losses of nitrogen from soil alone[2,3], but extrapolation of such results is limited. Wilson[4] and other workers[5–7] have used closed systems to study fixation, but normal conditions were not ensured and no attempt was made to follow gaseous changes. De and Mandal[8] measured the decrease in atmospheric nitrogen to estimate fixation by algae in flooded rice soils; however, their system did not enclose the whole plant. Some physiological experiments have involved closed systems[9], but these were short-term investigations lasting only a few hours. Normal plants labelled with carbon-14 have been produced in closed systems; the assembly described by Jenkinson[10] is a typical example. Here the volume was kept large to reduce the effects of the plants; small atmospheric changes would thus be undetectable. Moreover, the system was not strictly closed, and used an

artificial growth medium. Thus it seems that no assembly suitable for the following gaseous nitrogen changes in a soil : plant : atmosphere system has been previously described.

An extended period of growth in a gas-tight chamber presents several difficulties. First, some form of air conditioning inside the chamber is desirable to ensure suitable temperature and humidity, and to return transpired water to the soil. Secondly, removal of oxygen produced by photosynthesis is necessary if initial gas pressure and composition are to be maintained. Expandable rubber or plastic bags would keep the total pressure at 1 atm. but would allow an increase in pO_2; furthermore, such bags permit diffusion of gases and are thus unsatisfactory. Thirdly, an adequate supply of carbon dioxide must be maintained. Finally, a sufficiently accurate and versatile method of gas analysis is necessary.

Prototype Assembly. A 'Perspex' cylinder *A* (Fig. 1*a*), 50 cm long and 15 cm internal diameter with a wall thickness of 6 mm, is fitted with a flange at either end, 2·5 cm wide and 12 mm thick. The outer surface of each flange contains a machined rectangular groove in which a gasket seal *B* is seated; this consists of a length of 3 mm dia. latex. A circular end-plate is bolted to each flange by six wing nuts.

The top end-plate supports condensing coils *C* and contains gas inlet ports, a sampling port, and electrical connexions. Water vapour condenses on the coils, which are copper tubes of 6 mm diameter, silver-plated, and cooled by water at 5°–10° C circulated continuously from a refrigerated bath. Condensed water drips on to a shallow funnel-shaped annulus *D*, also plated, and thence flows into a glass siphon *E*. Use of this siphon avoids discharge of cold condensate directly to the soil and surface roots; by altering its capacity, different cycles of wetting and drying can be imposed on the soil.

Air circulation is provided by a fan *F*, mounted centrally in the upper part of the assembly within a short cylinder *G*. The fan axis, rotating on two bearings, is connected to a short length of soft iron *H* so that magnetic coupling can be used. Air movement is sufficient to mix the atmosphere thoroughly and ensure the efficient condensation of transpired water vapour; however, if close control of temperature were desired, it would be necessary to provide more efficient circulation since air near the top of the chamber is cycled more rapidly over the coils than air around the plant. Inclusion of a simple nichrome heating wire (not shown) allows some control of temperature, and humidity can be varied by changing the temperature of the cooling water.

Excess oxygen is removed by burning pure hydrogen at the end of a capillary in a microburner *J*, a larger drawing of which is shown in Fig. 1*b*, which also illustrates gasket seals used for the various entry ports and electrical connexions. When the pressure in the system rises a nichrome ignition spiral is switched on, hydrogen admitted, and excess oxygen removed in the small flame. Heat produced is dissipated by a thin nickel enclosure *K*. This device could be automated by providing a polarographic oxygen detector[11] to operate the ignition spiral and the hydrogen inlet valve simultaneously through an appropriate control system.

Pure carbon dioxide from a cylinder is admitted through a calibrated capillary leak for a specified period each hour, injection being automatically controlled by a solenoid valve connected to a time switch. The amount injected is somewhat less than the anticipated plant requirement, and is easily adjusted if gas analysis reveals an excess. It may prove possible to control the level of carbon dioxide automatically by using a pCO_2 electrode[11] as the sensing element in a control system.

A metal gauze screen *L* is necessary to prevent plants from entering the upper part of the chamber.

Light for a single chamber is conveniently supplied by short, vertical fluorescent tubes; for a number of chambers long horizontal tubes are more convenient. The addition of incandescent bulbs improves the quality of the light. It is necessary to ensure adequate ventilation of the lighting unit to prevent overheating the chambers; light intensities of 2,000 ft.-candles can be obtained without difficulty.

Mass Spectrometric Analysis of Gaseous Changes. The most suitable method of gas analysis is mass spectrometry (for which reliable methods are available[12–14]), since this provides an accuracy, versatility and convenience that other methods cannot match.

To measure small changes mass spectrometrically it is necessary to use a comparative method in which samples are compared with a standard mixture on a double-inlet mass spectrometer. It is convenient to use as standard a sample of the initial atmosphere.

If unit pressure of component j of a mixture is admitted to the mass spectrometer, the height of the largest resulting peak is by definition the (absolute) sensitivity s_j of the component; the height of the peak at mass i is $c_{ij}s_j$, where the set of numbers c_{ij} (i ranging over the peaks of the spectrum) is by definition the cracking pattern of the component. If unit pressure of the mixture gives a peak i of height H_i, then, subject to the usual assumptions[12]:

$$\sum_j c_{ij}s_j p_j = H_i \qquad (1)$$

where p_j is the partial pressure of component j.

It is convenient to select one component of the mixture, s, as an internal reference standard. Assuming that only this component contributes to the peak r:

$$c_{rs}s_s p_s = H_r$$

Defining relative sensitivities r_j and relative partial pressures x_j by the relations:

$$r_j = s_j/s_s$$

$$x_j = p_j/p_s$$

equation (1) becomes, on division by $s_s p_s$:

$$\sum_j c_{ij} r_j x_j = c_{rs} H_i/H_r \qquad (2)$$

The unit of pressure chosen is arbitrary, and small changes do not affect the cracking patterns and relative sensitivities. Hence, if the standard mixture taken from the chamber initially is admitted to one inlet vessel of the mass spectrometer and a later sample to the other, the pressures being adjusted to give approximately equal heights at peak r, we have from equation (2):

$$\sum_j c_{ij} r_j (x'_j - x_j) = c_{rs}(H'_i/H'_r - H_i/H_r)$$

where the prime refers to the later sample. If we let:

$$\Delta H_i = H'_i - H_i$$

this becomes:

$$\sum_j c_{ij} r_j (x_j - x_j) = c_{rs}(\Delta H_i - \Delta H_r H_i/H_r)/H' \qquad (3)$$

The change in the quantity of component j in the chamber is given by:

$$\Delta Q_j = M(x'_j - x_j)$$

where M is the quantity of component s present, assumed strictly constant.

The terms c_{ij}, r_j, and H_i/H_r are constants and need be measured only once. Hence, to analyse a sample, it is only necessary to measure H'_r and ΔH_r at peak r, and ΔH_i at enough peaks to allow the ΔQ_j of interest to be found; a complete analysis need not be made, which is an important advantage if there are many samples. The method also avoids the use of specially blended gas mixtures. The sensitivity is such that changes in a component in the 8-l. chamber of 0·1–0·5 per cent, or 1–5 μmol. (whichever is larger), can be detected.

The method outlined here can also be used for measuring large changes in a component if high accuracy is not desired; if high accuracy is necessary the use of a specially blended gas mixture in place of the initial atmosphere sample will allow the calculation of x'_j from equation (3).

For the experiments on fixation presented here the 20 peak of argon was used as an internal reference. A known quantity of krypton added to the chamber (which contained 60 per cent argon) enabled M to be calculated. It was initially intended to use the krypton as internal reference, but results calculated on this basis were rather variable, probably because of effects in the mass spectrometer inlet system arising from the relatively high molecular weight of this gas. The 20 peak of argon was used in preference to the 40 peak, which was too large for convenience. The change in excess nitrogen-15 in the atmosphere, $\Delta XS^{15}N$, was calculated from the formula:

$$\Delta XS^{15}N = \Delta Q_{^{14}N^{15}N} - \Delta Q_{^{14}N_2}/135 + 2\Delta Q_{^{15}N_2}$$

with the quantities on the right expressed in millimoles and $\Delta XS^{15}N$ in milli-equivalents.

Trial Experiments. To test the chamber and associated techniques in establishing a nitrogen balance, four experiments were run. Three of these (experiments 1, 2 and 3) used pots each containing two leguminous and two grass plants, labelled nitrogen gas being added to the atmosphere, while experiment 4 used four grass plants fertilized with labelled ammonium sulphate. Excess nitrogen-15 in the atmospheres was monitored by gas analysis, and at the end of the experiments excess nitrogen-15 in plants and soils was measured by Kjeldahl and nitrogen-15 analysis.

The plants used were *Phaseolus atropurpureus* var. 'Sirato', a legume which has shown promise as a pasture plant in Queensland, and *Chloris gayana* (Rhodes grass). Each pot contained 2 kg sandy loam soil of *p*H 5·6, any nutrient deficiencies (except that of nitrogen) being corrected by addition of fertilizer. Soil temperatures and matrix suctions during the experiments were 27° C and 0·1 bar for experiment 1, and 32° C and 0·2 bar for experiments 2, 3 and 4.

After an initial period in the glasshouse one pot was taken and placed on the bottom end-plate of the chamber, legume growth being cut back. The assembly was then placed over the pot and the unit sealed by tightening the wing nuts. An artificial atmosphere was introduced by flushing the system with commercial argon, evacuating to 0·75 atm., and adding oxygen to 1 atm. from an anæsthetic bag. In experiments 1, 2 and 3 labelled nitrogen gas was added in the same way. Finally, a known quantity of krypton (approximately 4 m.mol.) was added by displacement with water. Labelled nitrogen gas was prepared by reaction of alkaline hypobromite with an enriched ammonium salt and purified by passage through a liquid nitrogen trap; no peaks at masses 31 or 45 were detected on the mass spectrometer, indicating that no oxides of nitrogen were present.

During the experiments, soil temperature was measured with a thermometer and air temperature with a shielded thermistor; humidity was followed with a thermocouple hygrometer. Pressure was measured by movement of a metal diaphragm, as mercury vapour was found to be toxic to the legume, and other manometric fluids would permit diffusion of gases. All plants appeared healthy at the end of the experiments, although some of the older legume leaves were shed soon after the plants were introduced into the chamber. The grass in experiments 1, 2 and 3 made little growth in the nitrogen deficient soil, but that in experiment 4, which had received nitrogen fertilizer, soon filled the chamber.

Experiments 1, 2 and 3 were run for 26, 23 and 13 days respectively. The atmospheres contained 18, 29 and 16 per cent nitrogen with enrichments of 4·1, 3·4 and 7·1 atom per cent excess nitrogen-15. The rates of fixation of total nitrogen, calculated from the gas analysis data for nitrogen-15, were 3·2, 1·5 and 2·2 mg/pot/day. Fixation of unlabelled nitrogen could not be followed directly because air diffused against a positive pressure into rubber tubing connecting the cylinder of carbon dioxide to the systems; it was thus admitted with the carbon dioxide. Subsequent tests have shown other sources of leakage to be negligible, at least for periods of up to a month.

The excess nitrogen-15 in the atmosphere at the end of the experiments was estimated by regression analysis of the gas analysis data, since these appeared to lie close to a straight line. Total nitrogen was determined on dried (60° C) plant material and soil using the method of Bremner and Shaw[15], the ammonia being distilled into 30 ml. of 5 per cent boric acid. An aliquot of this was taken for electrometric titration with sulphuric acid and the remainder concentrated by redistillation into hydrochloric acid for isotope ratio determination. The results are presented in Table 1.

It is seen that the recovery of nitrogen-15 is close to 100 per cent. However, the 99 per cent fiducial limits on the atmospheric decreases in nitrogen-15 indicate that, for experiments 2 and 3, these decreases are significantly different from the increases in the soil : plant system. The cause of this slight discrepancy is not known. It is possible that adsorption of gases within the soil is responsible;

Table 1. Comparison of Excess Nitrogen-15 Removed from the Atmosphere with that found in the Soil : Plant System

Exp.	Decrease of excess ^{15}N in the atmosphere (m.equiv.)	Increase of excess ^{15}N in the soil : plant system (m.equiv.)	Recovery of total excess ^{15}N in the system (%)
1	0·245 ± 0·026	0·235	99·8
2	0·084 ± 0·016	0·067	99·8
3	0·146 ± 0·021	0·121	99·6

The 99 per cent fiducial limits from regression analysis are given for the decrease of excess ^{15}N in the atmosphere. The recovery of total excess ^{15}N is based on a determination of that originally present using a synthetic gas mixture for comparison. The decreases in experiments 1, 2 and 3 were 4·9, 1·2 and 2·2 per cent respectively of the excess ^{15}N originally present.

alternatively, there may be a systematic error in the gas analysis. Errors in the recovery of nitrogen-15 from the soil : plant component are considered to be too small to cause the difference. It is clear, however, that the detection of changes of a few per cent in atmospheric nitrogen-15 is considerably more accurate than the detection of similar changes in the soil : plant component where errors in the determination of total nitrogen make the detection of small proportional changes difficult. There is no reason why a similar accuracy should not be attained for unlabelled nitrogen, provided the system is free from leaks.

The partition of nitrogen-15 fixed is shown in Table 2. These results are interesting because of their variability, which indicates that under different conditions, as in these experiments, a considerable range of partition is possible. In particular, the amount of fixed nitrogen in the grass in exp. 1 is negligible, but in exp. 2 and 3 it is of practical significance. In exp. 3, for example, the total uptake of fixed nitrogen by the grass would correspond to approximately 20 lb./acre/yr. The large proportion of fixed nitrogen-15 in the soil in exp. 2 is thought to be a real effect and not largely due to poor separation of roots from soil. Further work in this direction using controlled conditions should prove fruitful.

Table 2. THE PARTITION OF FIXED EXCESS NITROGEN-15

Exp.	Percentage of total ^{15}N fixed in		
	Legume	Grass	Soil
1	91	0·07	9
2	67	1·2	32
3	84	2·3	14

Exp. 4 was run for 34 days in an atmosphere of 7 per cent unlabelled nitrogen, 10 per cent oxygen, 82 per cent argon, and 1 per cent krypton. The grass had received 12 m.equiv. (approximately 200 lb./acre) unlabelled nitrogen as ammonium nitrate one week before the pot was placed in the chamber. A further application of 12 m.equiv. labelled nitrogen (30 atom per cent excess nitrogen-15) as ammonium sulphate was placed in the water siphon; this was automatically applied the day after the experiment began. Peaks at masses 17, 29, 30, 31, 45 and 46 (corresponding to ammonia, nitrogen and oxides of nitrogen) were monitored. No change was detected at any of these peaks. From the data it was estimated that any loss of nitrogen-15 to the atmosphere which may have occurred in these forms was less than 5 μequiv. or approximately 0·1 per cent of that applied. The peak at mass 30 indicated that there was no loss of unlabelled nitrogen as N_2O, NO, or NO_2. These results serve to establish a lower limit to the sensitivity of the technique. It must be remembered, however, that any NH_3 or NO_2 present in the atmosphere would probably be absorbed in condensed water and returned to the soil.

Excess nitrogen-15 in the soil : plant component was determined as in the other experiments, tops, roots and soil being analysed separately. The recovery of excess nitrogen-15 was 101 per cent of that applied.

Discussion. The experiments described here show that the chamber can be successfully used to strike a nitrogen balance, even where changes in nitrogen are small. It may also find application in work not directly concerned with nitrogen balance. For example, McAuliffe *et al.*[16] have applied labelled nitrogen to legumes grown with grass and used the relative enrichments resulting as an indication of nitrogen fixation by the legumes. The chamber could be used to test the validity of the assumptions underlying this technique. Again, simultaneous fixation of carbon and nitrogen could be followed from day to day under controlled conditions. The chamber may also find uses, perhaps in an adapted form, in microbiological and plant-physiological work—for example, in studying the effects of artificial atmospheres. An important advantage of the chamber is its low cost, which allows ready replication.

We thank Mr. L. Cowper for constructing the chamber, and Dr. A. W. Moore for advice. Mr. D. J. Oxenham gave further assistance, and Miss Carolyn Patterson helped with analyses.

FLUTTERING FLIGHT MECHANISMS IN INSECTS AND BIRDS

By PROF. G. HOUGHTON

School of Engineering and Mines, University of Pittsburgh, Pennsylvania

RECENT analysis[1–3] has demonstrated that the fluttering lift behaviour of insects and birds can be explained by a non-linear force balance accounting for superposition of the forces derived from body acceleration, aerodynamic lift, gravitation and air acceleration, such that the model takes into detailed consideration all the following factors: (1) as in Nature, the present theory requires a true flapping motion about a point hinged to the body, in contrast to the non-flapping or wing-pitching model of Holst and Küchemann[4]; (2) an instantaneous force balance is used throughout the analysis so that it is unnecessary either to neglect portions of the stroke or to take time average forces, as in the approaches of Walker[5] and Osborne[6]; (3) unlike previous models, the present analysis permits the body to oscillate freely as observed experimentally for the locust by Jensen[7] and photographed during model ornithopter flight by Holst and Küchemann[4]; (4) an aerodynamic lift force is included by a term proportional to the square of the relative body-wing velocity during flutter, a form analogous to that proposed for insects by Osborne[6] and of the square-form conventionally used in experimental aerodynamics for systems in Helmholtz flow; (5) the lift coefficient C_L in the aerodynamic lift term is permitted to have different values on the downstroke (C_L^D) and upstroke (C_L^U) as postulated by most workers in the field of insect and bird flight[4–10], the largest value of C_L observed in laboratory experiments[11] on plane aerofoils in Helmholtz flow being

2·14; (6) the present theory accounts for the experimental observation[6–10] that the wing motion (wave-form) is non-uniform, such that the ratio of the time of lowering to the time of raising, or the duration factor k, may be in the range 1·0–1·8 depending on the particular insect or bird; (7) the important air acceleration term, not present in earlier models, arises because the wings, when acting as paddles, press on the ambient air with a force that varies from one part of the cycle to the next such that the mass of displaced air, multiplied by its acceleration, will generate a non-uniform reaction force on the wings—the nature of such displaced fluid forces in the analogous case of accelerating particle-fluid systems has already been discussed[12–14].

In the present case of flapping flight the air acceleration term has been formulated, as in particle-fluid systems, by requiring the mass of displaced air to carry along with it a virtual mass which is a fraction $\varkappa$ of the displaced air, the motion of this mass of accelerated air closely following the non-uniform trajectory of the wings, with the possible exception of a difference in phase ε. It is the uneven pressure of the wings on the ambient atmosphere, arising from the periodic but non-sinusoidal wing motion, which results in the non-uniform reaction force of the displaced air on the wings, the time integral of this net force over a complete wing cycle being cumulative over a succession of wing beats, as discussed later. The fluttering-lift equation, incorporating all of the foregoing phenomena, is a complicated two-dimensional integro-differential equation with time-varying coefficients that requires a high-speed digital computer for its numerical solution—such complexity indicates why insect and bird flight has proved so intractable to simplified approaches in the past[4–6], a situation which no doubt prompted Pringle[15] to summarize the status of insect flight in 1957 as follows: "It must be stated that there is at present no simplified picture of the mechanism of insect flight which can be used to derive a mathematical theory of the way in which lift and thrust are generated by wing motion".

That most of the force induced by wing flutter is used to overcome gravity and a much smaller percentage is needed to maintain uniform horizontal flight can be demonstrated fairly generally using available experimental flight data for insects[6–10]; for example, the results of Weis-Fogh[8,9] and Jensen[7,8] on the desert locust reveal the equivalent body diameter to be about 1 cm, the average steady flight velocity as 350 cm/sec with a measured drag coefficient on the wings of less than 0·1 for observed angles of attack in the conventional aerodynamic sense of 5°–10°, while the drag coefficient for the body at Reynolds numbers of 2,500 would be[16] about 0·4, so that the total body-wing form drag in horizontal flight using conventional aerodynamic gliding concepts is estimated to be less than 50 g cm/sec^2, as compared with the gravitational force of 1,960 g cm/sec^2 on a locust weighing 2 g. Similarly, the wing lift coefficient was found[7–9] to be less than 0·8 with angles of attack of 5°–10°, so that the maximum lift that could be generated by any forward horizontal gliding in the conventional aerodynamic sense is 320 g cm/sec^2; if the flight velocity were reduced by a half to 175 cm/sec the square law would reduce the lift to one-quarter its value, or 80 g cm/sec^2. Thus the frictional drag in horizontal flight is theoretically about 2–3 per cent of the gravitational force, as also found experimentally by Weis-Fogh[9] and Jensen[7], while the vertical lift generated by any forward gliding motion is probably less than 16 per cent of the downward gravitational pull, indicating that the insect is unstable in the conventional aerodynamic sense and also that at least 84 per cent of the lift must be generated by wing flutter. Since most measurements[6–10,17] of wing frequency and stroke angle for insects are probably no more accurate than ± 25 per cent, it seems quite reasonable to neglect lift and drag produced by forward motion in comparison with the overwhelming gravitational pull. Furthermore, it is common observation that many insects, such as the bee, can rise and descend vertically in still air with scarcely any horizontal components to the body motion. Thus the applicability of conventional aerodynamic gliding principles to insect flight must be held in serious doubt since the wings must serve the dual function of forward propulsion against the body form drag as well as vertical stabilization against gravity. From the physical point of view, forward motion by wing flapping in higher-order insects could be produced by giving the wing a time-varying angle of attack and permitting it to flutter with a horizontal component as well as a vertical component—that is, in one type of wing motion the tip might follow an elliptical Lissajous figure such as one might describe with an oar when rowing a boat, while, in another type of wing motion, with wing *twisting*, the trajectory might be that of a figure of eight. In the large-winged insects, such as the locust and moth, wing folding with only slight wing twisting are the most probable causes of forward motion, while in birds the most logical mechanisms for forward propulsion are wing warping and feather twisting, particularly of the primary remiges. However, as discussed here, the force required to maintain uniform horizontal flight against body-wing form drag is less than 3 per cent of the vertical component required to balance gravity in the locust, so that the treatment of the more complicated forward motion will necessitate greater refinements in both the theoretical and experimental techniques than have hitherto been contemplated. Another aspect of insect and bird flight apparently neglected in most treatments is the influence of body contours, particularly in birds and higher-order insects, since if forward propulsion is effected by 'wing-rowing', then the body might be aerodynamically shaped to provide maximum lift with minimum drag, these being problems in common with all conventional aircraft and hydrocraft.

Thus, since gravity is by far the most overwhelming force on a fluttering wing-body system at low forward speeds, the major problem of insect and bird flight is resolved into determining the relative importance in the present theory of the anti-gravity forces generated by the aerodynamic lift term and the air acceleration term in the fluttering lift equation (1) of the first article[1], which is rewritten in the more suitable integral form:

$$u(t) = -(\rho/M)\int_0^t C_L(\tau)\int_0^L W(r)\,\{u(\tau) - r\varphi P_\tau(k, \omega\tau)\cos[\varphi P(k, \omega\tau)]\}.$$
$$|u(\tau) - r\varphi P_\tau(k, \omega\tau)\cos[\varphi P(k, \omega\tau)]|\,\mathrm{d}\tau\mathrm{d}r - gt$$
$$- (\gamma\varphi/M)\int_0^t P_{\tau\tau}(k, \omega\tau + \varepsilon)\cos[\varphi P(k, \omega\tau)]\,\mathrm{d}\tau \qquad (1)$$

The instantaneous body velocity is $u(t)$, the ambient air density ρ being small compared with the body density ρ_L such that the mass of the insect $M \approx (\rho_L + \chi\rho)V \approx (\rho_L - \rho)V$ where V is the volume of the body the coefficient of virtual mass of which is χ. The periodic function $\varphi P(k, \omega\tau)$ simulates the non-uniform wing motion (wave-form) of angular half amplitude φ and overall angular frequency $\omega = 2\pi f$ such that the notation for derivatives is $P_{\tau\tau} = \mathrm{d}P_\tau/\mathrm{d}\tau = \mathrm{d}^2P/\mathrm{d}\tau^2$. The geometry[1–3] of the axially symmetric wings is governed by the chord length $W(r)$ as a function of the radial distance r from the fulcrum, the overall wing-length being L. The lift coefficient $C_L(\tau)$ is included in the time-integral so that it can take on the periodic values of C_L^D and C_L^U on the downstroke ($P_\tau \leqslant 0$) and upstroke ($P_\tau > 0$) respectively[2]. The acceleration factor $\gamma = 8\rho(1 + \varkappa)\varphi S m_2$ is based on the volume of air (plus virtual volume) displaced by the wings, the single wing area $S = \int_0^L W(r)\mathrm{d}r$ and the second wing moment $m_2 = (1/S)\int_0^L r^2 W(r)\mathrm{d}r$ being determined by graphical integration using equivalent two-wing geometries[1–3]. Tran-

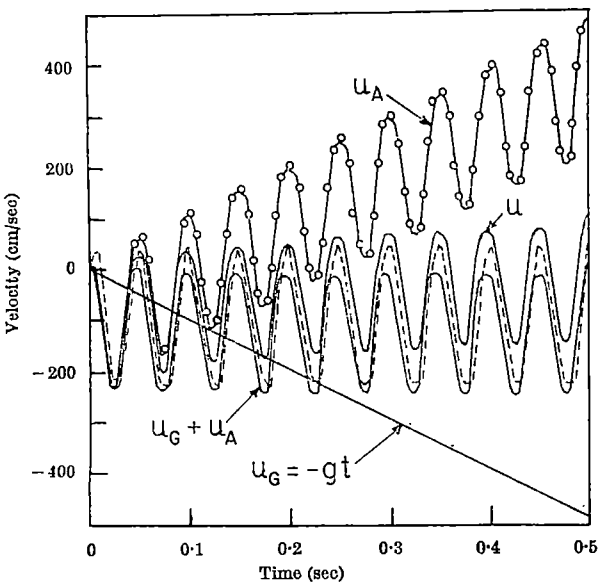

Fig. 1. Velocities u, u_A and u_G for the desert locust at $k = 1{\cdot}50$, the points (O) being U_A from equation (2) with $\mu = 0{\cdot}056$; the broken curve is u_A at $k = 1{\cdot}00$

sient velocity distribution effects, as generalized by a Basset term, have been presumed negligible for the reasons given earlier[1]. Using Stieltjes forms for the time integrals, equation (1) above has been solved numerically[1] on a high-speed digital computer (IBM 7090) starting with $u(0) = 0$ and $y(0) = 0$ to calculate $u(t)$ and the vertical distance $y(t) = \int_0^t u(\tau)\mathrm{d}\tau$. In the discussion which follows much simplification is achieved by assigning the functional symbol $u_L(t)$ to the first term on the right of equation (1) arising from aerodynamic lift generated by wing flutter, the symbol $u_G(t)$ to the gravitational term $-gt$ and $u_A(t)$ to the third term on the right arising from the integration of non-uniform air acceleration forces.

Some insight into the relative importance of the lift and acceleration terms, u_L and u_A, respectively, in relation to gravity u_G can be obtained by inspecting the vertical phugoids, $y(t)$ versus t, for the bird, locust, moth, fly and bee in the previous communication[3], it being found that the slope of the trajectory for $\gamma \equiv 0$, corresponding to no air acceleration forces, is about 15–35 per cent lower than that for free fall with no wing flutter, thereby indicating that if coupling effects are ignored the air acceleration term will contribute about 65–85 per cent of the total anti-gravity force for the case where $C_L^D = 2{\cdot}0$ and $C_L^U = 1{\cdot}5$, the wing wave-form being of the Z-type with phase lag $\varepsilon = -3\pi/4$. Higher aerodynamic lift contributions of 20–50 per cent have been found when $C_L^D = C_L^U = 2{\cdot}0$. Thus, while aerodynamic lift effects arising from wing flutter are not small, being on average 25 per cent of gravity, the major anti-gravity contribution of about 75 per cent comes from non-uniform air acceleration, thereby explaining why earlier theories of flapping flight, based solely on aerodynamic lift phenomena, were inadequate to explain insect flight.

In order to illustrate the behaviour of the non-uniform air acceleration term, Fig. 1 has been constructed based on Z-wave-form calculations for the desert locust at $\varepsilon = -3\pi/4$, $f = 20$ c/s, $\varphi = 0{\cdot}875$ rad, $k = 1{\cdot}5$, $C_L^D = 2{\cdot}0$, $C_L^U = 1{\cdot}5$ and $\gamma = 2{\cdot}80$ g cm, utilizing the equivalent two-wing geometry of Weis-Fogh and Jensen[8]. Clearly with $k = 1{\cdot}5$ the acceleration integral u_A exhibits a component oscillating in velocity around another component that increases linearly with time, this latter component being due to the non-uniformity of the wing motion since it disappears when $k = 1{\cdot}00$; it is this positive linear component that cancels the negative gravitational term $u_G = -gt$, the resultant $u_G + u_A$ being also plotted in Fig. 1 for comparison with the true body velocity u which contains the aerodynamic lift contribution u_L of equation (1) together with any coupling effects. A comparison of the velocities shows that the linear portion of u_A represents about 82 per cent of u_G, the remaining 18 per cent being accounted for by u_L and coupling effects, thus confirming the predominance of the air acceleration forces. Very similar results to those for the locust in Fig. 1 have also been obtained for the bird-, moth-, fly- and bee-types discussed previously[3]. Although not shown in Fig. 1, the magnitude of the linear contribution to u_A can be varied by changing the phase angle ε which modifies the interaction between the functions $P_{\tau\tau}(k, \omega\tau + \varepsilon)$ and $\cos[\varphi P(k, \omega\tau)]$ as demonstrated earlier[2], it being also shown that the Z-wave-form is more effective than the S-wave-form, the latter tending to produce phugoids which are relatively insensitive to the duration factor k. Since the non-uniform air acceleration integral appears to be composed of linear and oscillatory components, it seems reasonable to formulate a functional approximation U_A to u_A such that, for convenience in subsequent analyses, the two contributions are clearly separated as follows:

$$u_A(t) \approx U_A(t) = \mu(\gamma\varphi/M)(\omega_U^2 - \omega_D^2)t - (\gamma\varphi\omega^2/M)\int_0^t \cos(\omega\tau + \varepsilon)\cos(\varphi\cos\omega\tau)\mathrm{d}\tau \quad (2)$$

where ω_D and ω_U are the respective frequencies of the downstroke and upstroke segments of the Z wave-form such that the duration factor is $k = \omega_U/\omega_D$, the linear term yielding the necessary zero contribution when $k = 1{\cdot}00$; empirical coefficient μ denotes a dimensionless parameter the numerical value of which is adjusted to fit u_A as closely as possible—the fit of approximation (2) to the locust data with $\mu = 0{\cdot}056$ is shown by the points plotted in Fig. 1, similar agreement being found for the bird, moth, fly and bee when μ is 0·125, 0·099, 0·047 and 0·096 respectively, the corresponding flight parameters for these insects being tabulated in the previous article[3]. Equation (2) clearly identifies the two components present in the air acceleration term, thereby illustrating that the original non-uniform wave-form is modulated by interaction to generate a time-increasing portion and leaving a more uniform oscillatory component; it will be demonstrated in a future communication that approximation (2) serves as the basis for a general correlation of all the insect flight data of Magnan[10], Osborne[6] and Sotavalta[18], comprising 21 different insects belonging to the orders Lepidoptera, Neuroptera, Coleoptera, Diptera and Hymenoptera.

For the computing time on the IBM 7090 digital computer I thank the U.S. National Science Foundation through grant *GP*–2310, which partially supports the University of Pittsburgh Computing Center.

INDUCTION OF IMMUNITY AND OF UNRESPONSIVENESS TO PARENTAL MARROW GRAFTS IN ADULT F_1 HYBRID MICE

By Dr. GUSTAVO CUDKOWICZ
Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

Jackson Laboratory, Bar Harbor, Maine

PREVIOUS work has firmly established that transplanted bone marrow cells of several sub-lines of the *C57BL* (H-$2^b/H$-2^b) strain do not grow as well in X-irradiated *C3H* × *C57BL* (H-$2^k/H$-2^b) and *A* × *C57BL* (H-$2^a/H$-2^b) F_1 hybrids as in recipient mice of either of the parental strains[1,2]. Such hybrids have been designated resistant toward grafted parental marrow merely to indicate that they are not capable of supporting optimal growth of donor hæmopoietic cells, as compared with genetically compatible recipients. The frequency of success of such grafts in segregating backcross progeny and the marrow's growth pattern in F_1 hybrids heterozygous at known H loci or at defined regions of the H-2 locus indicated that hybrid resistance (or, conversely, deficient growth of *C57BL* marrow in F_1 hybrid recipients) was controlled by a genetic determinant closely associated with the K region of the H-2 locus, in linkage group IX[2,3]. *C57BL* marrow is capable, however, of sustained and optimal growth on transplantation into irradiated mice of strain *C3H*, an allogeneic recipient[1,2]. This finding has been interpreted to mean that genetic interaction (interallelic), rather than heterozygosis for a recessive gene, may be responsible for hybrid resistance, presumably by preventing or modifying the expression of one or more isoantigens of the parental H-2^b phenotype[2,3].

In view of the known characteristics of growth of *C57BL*/10 and *C3H* strain marrow cells[2], we regard *C57BL*/10*ScSn* or *B10* as the prototype donor strain for demonstrating the phenotype 'deficient growth of parental marrow grafts in hybrids' and *C3H*/*HeSn* or *C3H* as the strain representative of the more common pattern of growth of transplanted parental marrow cells, which is indistinguishable in hybrids and in isogenic recipients.

These two strains of mice were used in the present experiments in pairs with their related congenic lines[4]. Strain *C57BL*/10-H-2^d-old or *B10·D2* is congenic with *B10* except that it carries the H-2^d allele, derived from *DBA/2*, instead of H-2^b. Strain *C3H·SW* is congenic with *C3H* except that it carries the H-2^b allele, derived from a non-inbred Swiss mouse stock, instead of H-2^k. F_1 hybrids from crosses between the congenic pair *B10* × *B10·D2* (H-$2^b/H$-2^d) were prospective recipients for marrow cells gathered from *B10* and *B10·D2* donors, while *C3H·SW* × *C3H* (H-$2^b/H$-2^k) hybrids were prospective recipients for *C3H·SW* and *C3H* marrow cells. In either case, the parental strains had, by definition, a common genetic background but different H-2 alleles. The recipient mice were females exposed to 700 or 800 r. of 300-kV (peak) whole-body X-rays at the age of 12–15 weeks and injected intravenously with graded doses of nucleated cells a few hours later. Generally, each cell dose was given to a group of 5–10 mice. Marrow was obtained from the femurs and tibias of adult female donors; the cells were suspended in Tyrode's solution and counted with a Coulter electronic particle counter after red blood cells were lysed. Five days following transplantation of the marrow, its growth was assayed in each of the recipients by measuring the uptake of 5-iodo-2′-deoxyuridine-^{131}I, a specific deoxyribonucleic acid (DNA) precursor, in the spleen. For this assay, each recipient was given intraperitoneally 0·5 μc. of ^{131}IUdR (specific activity ~100 mc./mg, Nuclear Science and Engineering Co., Pittsburgh, Pennsylvania), and 17 h later each recipient was killed, its spleen removed, and the incorporated iodine-131 radioactivity measured by means of crystal scintillation counting. The splenic uptake of ^{131}IUdR was expressed in percentage of the total radioactivity injected. Parental marrow cells from a single preparation were generally grafted into isogenic and into F_1 hybrid mice at the same time; the relationship between the mean uptake of ^{131}IUdR in spleens of isogenic recipients and the number of cells injected into the animals 5 days prior to ^{131}IUdR labelling appeared to be linear on a logarithmic plot for *B10*, *B10·D2* and for *C3H·SW* marrow (Fig. 1, curve *A*), throughout a range of cell doses from $0{\cdot}1 \times 10^6$ to $1{\cdot}6 \times 10^6$ donor cells per recipient mouse. This indicates that the competence to proliferate on transplantation into genetically susceptible hosts was not different for cells carrying the H-2^b or the H-2^d alleles; it has been reported previously[2], and it is shown in Table 1, that *C3H* cells carrying the H-2^k allele are also comparable with cells of the aforementioned types with respect to proliferative activity in isogenic recipients. The marrow cells characterized by these four phenotypes differed markedly, however, with respect to their ability to proliferate in the spleens of F_1 hybrid recipients: *B10* and *C3H·SW* cells grew deficiently in *B10* × *B10·D2* and in *C3H·SW* × *C3H* F_1 hybrids, respectively (Fig. 1, lines *C* and *B*), whereas *B10·D2* and *C3H* marrow grew without detectable impairment in hybrids of the same

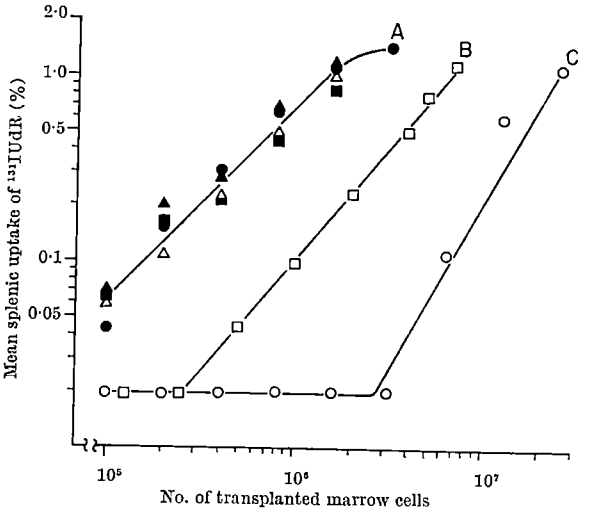

Fig. 1. Mean splenic uptake of ^{131}IUdR in relation to the number of bone marrow cells injected into X-irradiated (700 r.) recipient mice (five mice per point). Table 1. Proliferation of Transplanted Parental Marrow Cells in the Spleens of F_1 Hybrid Recipients pretreated with Parental Marrow or Skin Grafts

Donor Strain	Donor No. of grafted cells	Recipient Strain	Recipient Pretreatment	Mean splenic uptake of ^{131}IUdR (per cent ± S.E.)*
B10	10^7	*B10 × B10·D2*	Tyrode's	0·58 ± 0·04 (28)
			B10 marrow	0·12 ± 0·01 (25)
			B10·D2 marrow	0·60 ± 0·03 (27)
			B10 skin graft	0·73 ± 0·08 (13)
			B10·D2 skin graft	0·89 ± 0·10 (9)
B10·D2	10^6	*B10 × B10·D2*	Tyrode's	0·69 ± 0·05 (10)
			B10 marrow	0·59 ± 0·05 (10)
C3H	10^6	*B10 × B10·D2*	Tyrode's	0·61 ± 0·09 (10)
			B10 marrow	0·70 ± 0·10 (10)
C3H·SW	8×10^6	*C3H·SW × C3H*	Tyrode's	1·02 ± 0·04 (10)
			C3H·SW marrow	0·17 ± 0·03 (10)
			C3H marrow	0·99 ± 0·07 (10)
C3H	10^6	*C3H·SW × C3H*	Tyrode's	0·61 ± 0·06 (10)
			C3H·SW marrow	0·70 ± 0·07 (10)

*Mean uptake values are given as percentage of the total ^{131}IUdR radioactivity administered ± S.E. of the means, in excess of percentage retention of radioactivity in spleens of irradiated control animals not injected with marrow. The number of recipient mice is indicated in brackets; data of several independent experiments were pooled.

parentage (Fig. 1, curve *A*, and Table 1). Thus, the simple substitution of the *H–2*^{b} allele with *H–2*^{d} conferred to the marrow cells of *B10·D2* mice the ability to grow optimally in *H–2* heterozygotes, although the genetic background remained essentially that of the *B10* strain. Conversely, substitution of the *H–2*^{k} allele with *H–2*^{b} conferred on the marrow cells of *C3H·SW* mice the trait for deficient growth in *H–2* heterozygotes, despite the *C3H* genetic background of such mice. Differences in strength of hybrid resistance were noticeable, however, on comparison of the uptake-cell dose responses in F_1 hybrids from *B10* or *C3H* parents (Fig. 1, lines *B* and *C*). This observation raises the question whether or not the strength of hybrid resistance is modified by the genetic background of the parental strains entering the F_1 cross. Alternatively, the observed differences in strength of hybrid resistance might reflect dissimilarities in the *K* region of *H–2*^{d} and *H–2*^{k} with regard to the factor(s) involved in hybrid resistance.

Since *H–2* isoantigens are thought to be of primary importance in deciding the fate of allogeneic tissue grafts[5,6], it is conceivable that the *H–2* controlled hybrid resistance may reflect differences in isoantigenic constitution between the tissues of *H–2*^{b}/*H–2*^{b} parental mice and those of their heterozygous hybrid recipients. If this were the case, one would expect that hæmopoietic cells of the strains *B10* and *C3H·SW* would be antigenic to their resistant hybrids and capable of inducing a state of sensitivity or of unresponsiveness in such hybrids towards parental marrow grafts. To test this possibility, adult hybrid mice were given one of the following treatments before irradiation and infusion with parental marrow cells: (1) intraperitoneal injection at weekly intervals of $1{\cdot}5 \times 10^7$ nucleated, viable parental marrow cells for a total of three injections; (2) intraperitoneal injection at weekly intervals of 2×10^7 nucleated, viable parental spleen cells for a total of four injections; (3) transplantation on to the mid-dorsal region of parental skin tissue taken from the donor's ear; and (4) intraperitoneal injection at weekly intervals of Tyrode's solution for a total of three or four injections. Seven days after the last of the cell injections, or 100 days after placing the parental skin grafts (accepted and in perfect condition throughout), the hybrids were irradiated and infused with a single fixed dose of parental strain or allogeneic strain marrow cells. Five days later the extent of grafted marrow proliferation was assessed by the ^{131}IUdR assay. To detect immunity, that is, an induced state in which parental marrow grafts become unacceptable to F_1 recipients which otherwise would accept them, we grafted a dose of parental marrow cells known to override the resistance of non-sensitized hybrids (Fig. 1, lines *B* and *C*, and Table 1). On the other hand, to detect unresponsiveness, an induced state in which parental marrow grafts become acceptable to recipients which otherwise would reject them we grafted a dose of parental marrow cells known not to grow detectably in non-pretreated hybrids.

The promotion of splenic incorporation of ^{131}IUdR by 10^7 transplanted *B10* marrow cells in *B10 × B10·D2*F_1 hybrids was inhibited when the hybrids were pre-injected with *B10* marrow (Table 1, upper section). However, such an effect was not observed when the hybrids were pretreated with *B10·D2* marrow or with skin grafts of either parental strain before X-irradiation and infusion with the *B10* marrow test-graft. Furthermore, the pretreatment with *B10* marrow, which resulted in reduced acceptance of the *B10* test-grafts by the F_1 hybrids, did not affect the acceptance of marrow test-grafts from parental *B10·D2* and from unrelated *C3H* donors. Similar results were obtained with *C3H·SW* marrow grafts given to a comparable series of *C3H·SW × C3H* F_1 hybrids (Table 1, lower section). Thus, the induction of enhanced hybrid resistance resembles the induction of transplantation immunity, in that it is effected by the parental cells towards which the hybrid host was known to be resistant but not by the parental marrow cells or by the parental skin grafts which were known to be histocompatible with the hybrids. Furthermore, once established, this condition was specific for cells identical with those used for sensitization.

In contrast to the previous findings, pre-injection of resistant hybrid mice with parental spleen cells instead of parental marrow cells did not enhance the hybrid resistance and led, rather, to an opposite effect, that is, to the abrogation of hybrid resistance (Table 2). This was accomplished when the hybrids were given multiple injections of spleen cells from their *H–2*^{b}/*H–2*^{b} parents over a period of 4 weeks, whereas similar treatment with spleen cells of their parent which carried an *H–2* allele different from *H–2*^{b}, or with skin grafts of either parental strain, was ineffective (Table 2). That injected spleen cells have a tendency in certain circumstances to yield specific unresponsiveness in adult allogeneic mice has been reported by several investigators[7]. In this study, a similar condition has been established in F_1 hybrid mice

Table 2. Proliferation of Transplanted Parental Marrow Cells in the Spleen of F_1 Hybrid Recipients pretreated with Parental Spleen or Skin Grafts

* Donor and recipients were females. Recipients were exposed to 800 r. of X-rays before spleen cell infusion (4–5 mice per group).

† *B10* mice were sensitized against *B10·D2* isoantigens; *C3H·SW* mice were sensitized against *C3H* × *B10* F_1 isoantigens.

‡ The cell mixture was prepared a few minutes before the infusion into recipient mice.

§ The spleens of 11 suspected chimeras were tested 28 days after the first of four injections with *B10* or *C3H·SW* spleen cells. Eleven additional tests not reported in the table were made 32 days later with identical results.

towards parental *B10* and *C3H·SW* marrow grafts, provided that the exposure of the hybrids to the injected parental spleen cells was of sufficiently long duration. The extent of the hybrid's unresponsive state was estimated by comparing the splenic uptake of ^{131}IUdR in isogenic recipients and in pretreated hybrid recipients given test-grafts from a common pool of parental marrow cells (Table 2, lower section). Injected spleen cells of either *B10* or *C3H·SW* mice were capable of inducing unresponsiveness to *B10* marrow grafts in *C3H* × *B10* F_1 hybrids. Even though the abrogation of hybrid resistance induced by *C3H·SW* spleen cells was not as complete as that induced by *B10* spleen cells, the spleen cell factor(s) responsible for induction of unresponsiveness appeared to be similar in the two unrelated homozygous *H–2*^{b} strains, *B10* and *C3H·SW*.

It has been reported that F_1 hybrid mice infused with large doses of parental strain spleen cells sometimes become cellular chimeras[8]. Therefore, we determined the solubility and crystallographic properties of peripheral blood hæmoglobin[9] in *C3H* × *B10* F_1 hybrids, 28 and 60 days after the first of four injections with spleen cells of *B10*, *C3H·SW*, or *C3H* mice. If chimerism resulted from the injections of spleen cells, increasing amounts of donor-type hæmoglobin should become detectable as host erythrocytes age and disappear from the circulation. All the hybrids injected with *B10* or *C3H·SW* spleen cells became non-resistant to *B10* marrow grafts, as determined 7 days after the last injection (Table 2, lower section). At this time, as well as 32 days later, they did not contain detectable amounts of donor-type hæmoglobin in their blood. *C3H* × *B10* F_1 mice treated with *C3H* spleen cells also failed to become blood chimeras at similar time-intervals after the treatment. The spleens of hybrid mice which received multiple injections of parental cells were also tested for the presence of donor-type hæmopoietic spleen cells by transplantation, as described in the following. Cell suspensions were prepared from each hybrid spleen under test, and known numbers of such cells, varying from 2×10^7 to 4×10^7, were injected into irradiated *B10* or *C3H·SW* recipients, that is, into recipients isogenic with the donors of the spleen cells used to abrogate the hybrid resistance.

Prior to this cell injection the mice received intraperitoneally 50 U.S.P. units of heparin to prevent sudden death during or immediately after intravenous administration of large numbers of spleen cells. Half the *B10* or *C3H·SW* hosts were sensitized against isoantigens of the F_1 hybrid spleen donor by two intraperitoneal injections of 5×10^6 spleen cells each, given 1 and 2 weeks, respectively, before the test. This was done to prevent hybrid spleen cells from proliferating in such hosts on transplantation without impairing, however, the proliferation of eventually admixed parental-type spleen cells. Proliferation of the grafted cells was evaluated by the ^{131}IUdR method as described above, except that an intraperitoneal injection of 10^{-7} mole of 5-fluoro-2′-deoxyuridine (FUdR, gift from Hoffman LaRoche, Inc., Nutley, New Jersey) was given to the recipient mice 1 h before the ^{131}IUdR injection. FUdR is an inhibitor of the endogenous synthesis of thymidilate and reduces the competition of the latter with ^{131}IUdR for incorporation into DNA. Hence, it increases the incorporation of ^{131}IUdR in a given population of cells and therefore the sensitivity of the assay. Cells isogenic with the irradiated recipients (that is, *B10* or *C3H·SW*) were equally capable of promoting splenic incorporation of ^{131}IUdR when transplanted alone or as a mixture with F_1 hybrid cells (Table 3). The latter cells, however, were not capable of growth in presensitized recipients, their viability being established by their successful growth in unsensitized recipients (Table 3). Spleens of 22 suspected F_1 hybrid chimeras were analysed 28 days and 60 days after the first of four parental strain spleen cell injections. No spleen contained transplantable hæmopoietic cells other than those carrying the isoantigens of the hybrid donor (Table 3).

The proliferation of transplantable hæmopoietic stem cells contained in 2×10^5 nucleated parental strain spleen cells was readily measured by the ^{131}IUdR technique; since we transplanted approximately one-quarter of all the nucleated cells of a whole F_1 hybrid spleen into each of the recipients, we could, in fact, have detected the presence of one parental strain stem cell in 200–400 hybrid-type stem cells, depending on the total number of nucleated spleen cells infused (Table 3). Our findings do not exclude, however, that spleens of the unresponsive F_1 hybrids contain other parental type cells which are not hæmopoietic and do not proliferate on transplantation, as, for example, long-lived small lymphocytes.

It is suggested that induced enhancement and induced abrogation of hybrid resistance to marrow grafts from *H–2*^{b}/*H–2*^{b} donors reflect acquired immunity and unresponsiveness, respectively, to cellular isoantigen(s) of the *H–2*^{b} phenotype not present in *H–2*^{b} heterozygous F_1 hybrids. The failure of parental skin grafts from homozygous *H–2*^{b} donors to affect the response of F_1 mice to the postulated parental isoantigen(s) is in keeping with the lack of hybrid resistance to parental skin grafts[2,10] and with the lack of detectable hybrid-anti-parent humoral antibodies[5,11]. For these reasons, experiments based on rejection of skin grafts and on induction of hæmagglutinating antibodies have failed to detect this phenomenon[5,11].

In vitro CYTOTOXIC EFFECT OF LYMPHOID CELLS FROM MICE IMMUNIZED WITH ALLOGENEIC TISSUE

By DR. TAPANI VAINIO and DR. OLLI KOSKIMIES

IT is generally agreed that lymphoid cells have a decisive role in transplantation reactions *in vivo*. Although the mechanism of their action is unknown, it is of interest in this connexion that lymphocytes from mice immunized with allogeneic transplants can cause a cytolytic destruction of cells from the donor strains *in vitro*[1–4]. This effect is immunologically specific and does not seem to be complement-dependent.

When target cells were labelled with ^{14}C-thymidine and exposed to isoantibodies *in vitro*, the release of radioactivity into the medium after trypsin treatment was found to be correlated to the cytotoxic response as determined by supravital staining[5]. A similar method was applied for measuring the effect of immune lymphoid cells on labelled donor cells *in vitro*. Observations made in parallel on the morphology of the target cells will also be described.

Mice were immunized against allogeneic tissues derived from foreign genotypes differing at the *H*-2 locus in all cases except one. Skin, tumour tissues or spleen, liver and kidney were used as indicated in Table 1. The target cells were taken from mice of the strain used as tissue donor for immunization. Cells were isolated from whole 16–17-day-old fœtuses by trypsinization, or from adult lungs and kidneys, and were cultivated in milk dilution bottles[6]. Second or third sub-cultures were made on coverslips (1 cm × 1 cm) in small Petri dishes. The culture medium in all experiments consisted of Eagle's basal medium in Earle's balanced salt solution containing 0·0172 M sodium bicarbonate and 10 per cent heat-inactivated (30 min, 56° C) calf serum. The cultures were incubated at 37° C in 5 per cent carbon dioxide in air.

For morphological observation of the cytotoxic reactions, the coverslips were transferred to Petri dishes (1 coverslip/dish) and placed under stainless-steel screens (1 cm × 1 cm) of the type introduced by Trowell for organ culture[7]. Each screen was covered by lens paper and the dishes were filled with medium up to the height of the lens paper[7,8]. Axillary and inguinal lymph nodes, spleen and thymus, or spleen only, were removed from the immunized mice, cut into small pieces, washed twice and placed on top of the lens paper. All lymphoid material removed from one mouse was placed on the screen in one culture dish. Control material was taken from mice syngeneic with target cells. The controls were either from untreated mice, or from mice inoculated with syngeneic or allogeneic tissue.

After varying times of exposure, the coverslips were fixed and stained with hæmatoxylin–eosin. In the experiments with embryonic fibroblasts, no obvious cytotoxic effect of the immune lymphoid cells was found. Numerous lymphocytes and also a few polymorphonuclear cells had fallen down from the screens. Lymphocytes gathered around the target cells, but no abundant lysis was observed up to 72 h, and the number of target cells remaining on the coverslips appeared to be similar to that in the controls, even when the seeding of the cells on the coverslips was sparse.

In contrast, adult kidney or lung fibroblasts were more susceptible to immune lymphocytes. In the immune systems, a large proportion of the cells disappeared from the coverslips within 24 h, while no apparent change in cell number was seen in the controls (Figs. 1 and 2). Furthermore, the cells remaining on the glass in the immune systems were covered by aggregated lymphocytes and had a vacuolated cytoplasm. Addition of fresh guinea-pig serum (final dilution, 1 : 20) to the incubation medium did not affect the results, which were similar to those found by other authors[1–4]. The reason for the apparent resistance of the embryonic cells is unknown, although the lesser concentration of isoantigens on their surface may be suspected to play a part[9].

For the isotope experiments only embryonic fibroblasts were used. Second or third passage cultures on coverslips in Petri dishes were incubated overnight in medium containing either 0·5 μc./ml. of ^{14}C-thymidine (Radiochemical Centre, Amersham, England; spec. act. 0·1 mc./0·83 mg).

For each experiment, coverslips from one Petri dish were washed three times with buffered saline (PBS) and were then transferred to fresh dishes under stainless-steel screens (one screen/dish) as described above. One or two screens were loaded with lymphoid material from immunized animals, or two others with lymphoid material from control mice, whereas some screens in control dishes were left empty. The volume of the incubation medium in each dish was 13 ml. After incubation for 11–45 h the coverslips were removed and washed again three times with PBS. Each coverslip was treated for 15 min with 2 ml. 0·5 per cent trypsin, and the cells were spun at 2,000 r.p.m.

for 10 min. The cell sediment was treated with ice-cold 5 per cent trichloroacetic acid (TCA) and the precipitate formed was then washed once with TCA (5 per cent) and with absolute alcohol and alcohol + ether (3 : 1). For determination of carbon-14, the precipitates were dissolved in formic acid and the radioactivity was measured at infinite thinness with a thin-windowed Geiger–Müller tube in an automatic gas flow counter after drying on plastic planchets. The values in Table 1 show the total acid precipitable radioactivity (c.p.m.) of the cells recovered from a coverslip after incubation, washing and trypsinization. In addition, the acid-soluble as well as the acid-precipitable radioactivity of the trypsin solutions, and of aliquots of the incubation media, were determined in the same way. In some experiments, unlabelled DNA (0·4 mg/sample) was added as carrier.

Table 1 shows the results of a series of eight experiments. As can be seen, the acid-precipitable radioactivity recovered from the cells exposed to immune lymphoid cells was approximately 20–40 per cent less than that found in the controls when fresh lymphoid material was used (Exps. 5–8). This effect was seen only in 2 of 4 experiments in which the lymphoid material had been precultivated for one or two days (Exps. 1–4). (The positive results of Exp. 4 are questionable because of infection found in the sister culture.) No significant loss of isotope was noted in the cultures exposed to control lymphoid cells as compared with the unexposed control cultures. A measurable loss could already be recorded after 11 h of incubation. Addition of guinea-pig serum had no effect, although its concentration under the present conditions may have been too low for complement action.

As can be seen from Table 1, the immune cells were active 4–10 days after the last challenge of the mice with antigen. These results were confirmed in a series of similar experiments, where pieces of spleen from *C3H* mice immunized with *C57BL* spleen, were added to embryonic fibroblasts of *C57BL* mice. In this series, the immune spleen cells exhibited a cytotoxic action from 2–10 days after challenge. Control spleens from *C3H* mice inoculated with syngeneic tissue or with tissue from unrelated allogeneic mice (*AKR*) were inactive.

In the previous experiments[6], the cytotoxic effect of iso-antibodies was determined by measuring the isotope released from the damaged target cell into the incubation medium after trypsin treatment. In the work recorded here, the content of isotope of the trypsin solutions, as well as that of the incubation media, was low, and no differences were found between immune systems and controls. However, since the volume of the incubation mixtures was large and since some cellular material may have been lost during washing of the coverslips after incubation, isotope may have escaped detection. Until it has been established where and in which form the missing isotope can be recovered, it cannot be decided whether the present difference between immune systems and controls was due to a release of isotope from damaged cells, or to the escape of cells from the coverslips. It should be noted, however, that the morphological observations of these embryonic cells (see foregoing) showed no striking difference in cell numbers between immune and control incubations.

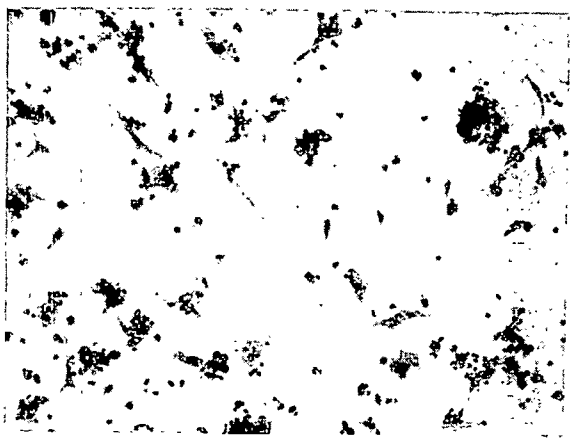

Fig. 1. Adult *A.SW* lung fibroblasts (second passage) after overnight exposure to immune lymphoid tissue from one *A* mouse immunized with *A.SW* sarcoma (MSWB) (Table 1)

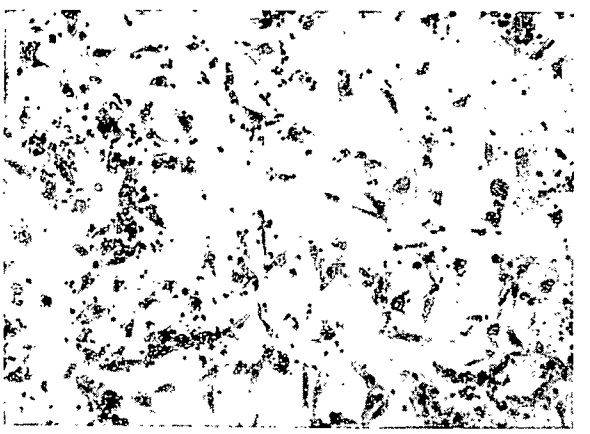

Fig. 2. Parallel control culture. Fibroblasts exposed to lymphoid tissue from one *A* mouse inoculated with syngeneic cells

In conclusion, it may be stated that even in cases where morphological observation gave no clear-cut results, the *in vitro* cytotoxic effect of immune lymphoid cells could readily be detected by the technique described here. The cytotoxic action of the lymphoid cells on the embryonic fibroblasts was immunologically specific. Although serum from the immunized mice had no cytotoxic effect under the present conditions, it cannot be excluded that the effect was mediated by antibodies of γ-globulin type, adsorbed to or synthesized by the aggregated lymphocytes[10–12].

It also remains to be established whether or not the reduced activity of the lymphoid tissue after ageing for 1–2 days in culture was significant. It is well known that isolated lymphoid tissue may retain its capacity to produce antibody during several weeks in culture[13,14].

INTESTINAL CRYPT LESIONS IN NEONATALLY THYMECTOMIZED HAMSTERS

By Dr. RICHARD C. HARD*, Prof. CARLOS MARTINEZ† and Prof. ROBERT A. GOOD‡

Pediatric Research Laboratories of the Variety Club Heart Hospital and Department of Physiology, University of Minnesota, Minneapolis

THE fatal wasting syndrome following neonatal thymectomy in the golden hamster includes diarrhœa, marked loss in weight, pancytopenia[1] and immunological deficiency[2]. The basic mechanism of these changes is unknown. Work recorded here describes the characteristics and incidence of intestinal crypt lesions in hamsters thymectomized at birth, which may account for the diarrhœa and wasting of these animals. The high degree of correlation between the occurrence of enteropathology and alterations in the ratios of circulating white blood cells is noted.

A total of 274 new-born golden hamsters (obtained from Simonsen Laboratories, White Bear Lake, Minnesota) from 31 litters were divided into three groups of 143 thymectomized, 76 sham-thymectomized controls (sham) and 55 intact controls (controls). Thymectomy within 24 h of birth was carried out by the method of Sjodin *et al.*[3]. In all but two litters, litter mates of the thymectomized animals were subjected to sham operation involving exposure of the thymus without removal. The intact controls from separate litters were anæsthetized in ether and toe marked.

Blood for differential white blood cell counts was obtained following decapitation of the one- and two-week-old animals, or from the retro-orbital plexus in older animals immediately prior to death. All animals were killed by decapitation following ether anæsthesia. Twelve of the 18 thymectomized animals three weeks of age and more were killed when one or more signs of the syndrome appeared. The remainder appeared healthy but were killed to provide representatives of a particular age-group to complete the sequential study. Sham-operated and control animals were killed in each age-group. Complete gross and microscopic autopsy studies were performed on all animals used in this work. The tissues obtained were fixed immediately in 10 per cent formalin and prepared for histological examination. One-cm lengths of small bowel, usually including lymphoid aggregates, and of colon were sectioned longitudinally for more extensive evaluations of the intestinal mucosa. This report includes all animals 1–8 weeks of age, the tissues of which were adequate for complete histological investigations and the differential white blood cell counts of which were available. No attempts other than morphological observations were made to determine the presence of bacterial or viral agents.

Survey of all animals showed some differences between the experimental and control groups. The two-week survival rates of 38 per cent for the thymectomized animals versus 49 per cent for the control groups probably reflected the traumatic effects of neonatal manipulations. In general, the thymectomized hamsters showed an early gain in weight comparable to the controls, but then failed to gain, or lost, weight. The incidence of post-thymectomy wasting was about equal in the two sexes. There was no apparent correlation between the clinical conditions of the experimental animals at the time of death and the two parameters of this work, enteropathology and percentage of circulating lymphocytes.

This article will concentrate on the pathology of the intestinal crypt lesions diffusely scattered throughout the small bowel in 14 of 18 weaned, thymectomized animals. The lesions were of two types, both of which might occur in the same animal. The more distinctive (Fig. 1) appeared to comprise a disorderly proliferation of large vacuolated cells. The earliest changes in afflicted crypts included a loss of the bright red staining granules of the base cells (Paneth cells) and a slight disorganization in the orderly arrangement of the columnar lining cells. The cytoplasm of the cells became pale and swollen. The decreased intensity of nuclear staining suggested decreased nuclear chromatin content. Compression of surrounding tissue and the continued presence of mitotic figures suggested that excessive proliferation of the crypt cells had been involved in these lesions. Inflammatory response to these lesions was variable but usually minimal. No viral inclusion bodies were seen. The second type of lesion was an inflammation at the base of the crypts. There was usually flattening of the crypt lining cells, minute erosions occurred, and micro-abscesses formed (Fig. 2). The acute inflammatory reaction often involved the supporting connective tissue (lamina propria). It seemed to us that the best interpretation of these lesions was that both types were due to abnormal regeneration of crypt lining cells. In one case, the regenerative process could be considered defective, and in the other inadequate.

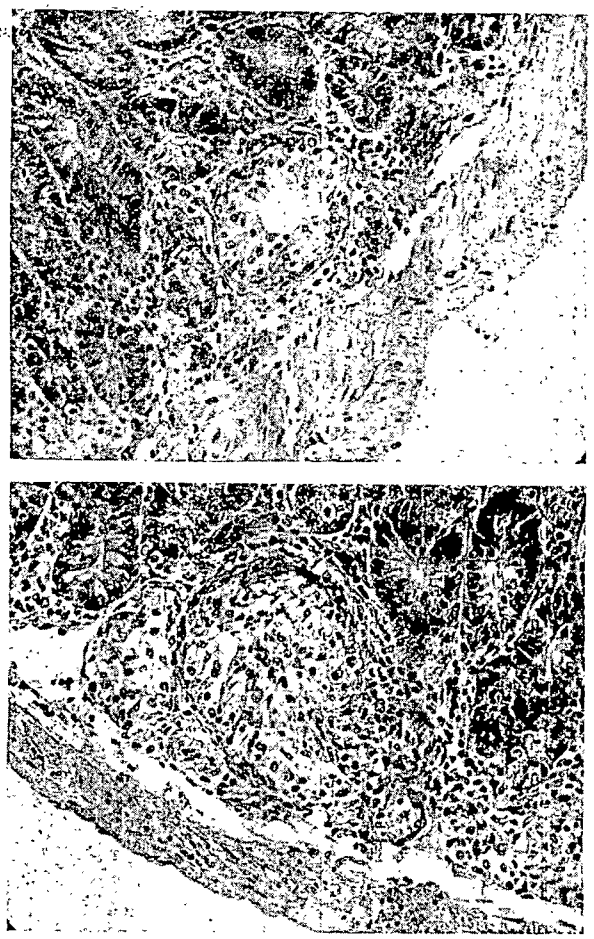

Fig. 1. Proliferative intestinal crypt lesions of neonatally thymectomized hamsters. Above, moderately advanced lesion typically located inside the muscularis with crypt architecture partially maintained by large vacuolated cells around dilated lumen; below, advanced lesion with central cell necrosis and slight acute inflammatory reaction. Note lesser involvement of two adjacent crypts (hæmatoxylin and eosin, × *c.* 133)

Histological survey of the other tissues of the thymectomized animals revealed only sporadic examples of significant tissue alterations, none of which appeared to be of infectious ætiology. Lymphocytic depletion in lymphoid organs was variable. It is of interest that the only examples of acute inflammatory lesions outside the intestinal tract which might be attributed to bacterial agents were found in three animals from the sham and control groups.

Lymphopenia has long been known to follow thymectomy. In this series, the designation of lymphopenia was an arbitrary one, representing a drop in the percentage of lymphocytes by one-quarter or more from an average level of 70 per cent. This average figure was obtained from the differential white blood cell counts of the sham and control animals found to be free of disease at autopsy. On this basis, it can be seen from columns I and III of Table 1 that lymphopenia occurred in 16 of 18 experimental

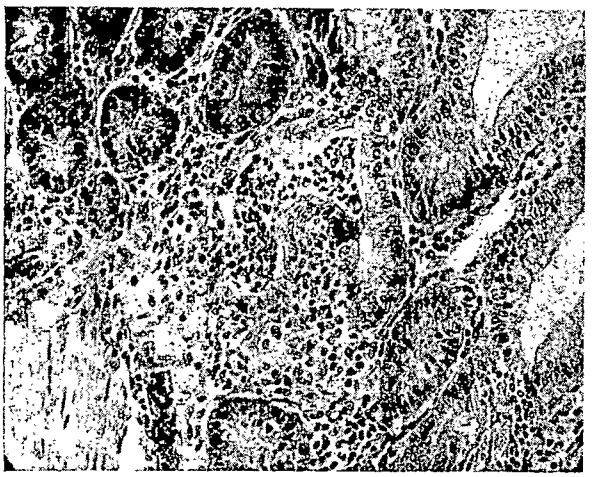

Fig. 2. Acute inflammatory intestinal crypt lesion of neonatally thymectomized hamsters (hæmatoxylin and eosin, × *c.* 133)

animals three weeks of age and over. The average proportion of lymphocytes in these 16 lymphopenic animals was 29 per cent with a range of 6–52 per cent (versus a range of 55–90 per cent in the two control groups). Although the experimental plan for this series of animals did not include total white blood cell counts to rule out a leucocytosis perhaps secondary to bowel inflammations, the hæmatological data of our pilot experiments were in agreement with the hæmatological data of Sherman *et al.*[1] and Defendi *et al.*[2], and indicated that the lymphopenia of thymectomized hamsters is both relative and absolute.

The association of intestinal crypt lesions and lymphopenia in 13 of 18 (72 per cent) neonatally thymectomized hamsters three weeks of age and older contrasted markedly with the absence of coincident lymphopenia and crypt lesions in sham-operated and control groups. The apparently normal hæmatological and enteric status of the thymectomized hamsters during the first two weeks is striking. Four additional thymectomized animals had crypt lesions, but were not included in Table 1 because differential counts were not available.

The five animals in the experimental group which did not show lymphopenia and crypt lesions were of interest. One had normal circulating lymphocyte levels and intact bowel mucosa; despite thorough search, no thymic remnant was found. Three animals had lymphopenia but no crypt lesions. The fifth animal which had crypt lesions without lymphopenia proved to be the major exception of the series. The crypt lesions noted in one sham animal (column IV of Table 1) were part of a diffuse ulceration of bowel adherent to a large liver abscess.

Microscopic thymic remnants were found in 4 of 34 animals in the thymectomized group after sectioning the thymic bed tissue at a frequency of approximately 70μ. All four of these animals showed lymphopenia and three of the four had crypt lesions. The development of one or more signs of the post-thymectomy syndrome despite the presence of minute thymic fragments in these animals suggested that a minimal amount of thymus may be

required for maintenance of lymphopoiesis and normal body economy.

The occurrence of these crypt lesions in thymectomized hamsters, and more recently in mice[4], raises the question of ætiology. It would be of great interest to know whether the enteric pathology is an independent occurrence or whether it is sequentially and causally related to the lymphopenia which occurs in such animals. It is possible that neonatal thymectomy removes the source of a humoral substance capable of direct action on the metabolic processes of the mucosal crypt cells. However, the high degree of association of lymphopenia with crypt lesions, and of normal lymphocyte levels with normal intestinal mucosa, suggested to us that these lesions might reflect the need of the rapidly proliferating crypt cells for components normally provided by the lymphocytes. Bryant[5] found, for example, that cells of the intestinal crypts took up radio-tagged DNA precursor from lymphocytes. These morphological and radioisotopic investigations would be in keeping with the idea that one function of the lymphocyte is to act as a nucleoprotein trephocyte[6]. The three thymectomized hamsters with lymphopenia but lacking crypt pathology, and the one thymectomized animal with normal lymphocyte count and intact mucosa, might indicate that lymphopenia preceded the intestinal lesions.

It is also possible that the enteric lesions are due to a latent virus activated in a weakened host as was recently observed with a hepatotrophic agent[7] found in neonatally thymectomized mice. Some of the characteristics of the crypt lesions would be compatible with this view. There is the additional possibility that our observations reflect the direct action of an auto-immune process as suggested by deVries *et al.*[8], and that these lesions are similar in pathogenesis to the crypt lesion observed earlier in animals undergoing homologous disease[9]. On the other hand, it is quite conceivable that the crypt lesions found in animals suffering from homologous disease are due to the lymphoid tissue deficiency known to accompany the graft-versus-host reaction[10].

A REINTERPRETATION OF THE VISCERAL SKELETON OF *Acanthodes*

By DR. R. S. MILES*

Naturhistoriska Riksmuseum, Paleozoologiska avd., Stockholm

IN a work of cardinal importance on the Acanthodii, Prof. D. M. S. Watson[1] attempted to demonstrate that these gnathostome fishes had a fully developed prehyoid (spiracular) gill-slit, and a little-modified hyoid arch skeleton which played no part in the suspension of the upper jaw. He also argued that this was true of the various groups of placoderms, and these he grouped with the acanthodians in the grade Aphetohyoidea. He believed the Aphetohyoidea to occupy an intermediate position between the Cyclostomata and Pisces with regard to the modification and incorporation in the jaw apparatus of the anterior visceral arches.

Several workers[2–5] have doubted that the aphetohyoid condition obtained in either the Acanthodii or Placodermi. Watson's arguments are overtly less strong where they concern the latter group, and Stensiö[6] has convincingly demonstrated that the hyoid arch is strongly modified in many placoderms, and that they did not have a complete spiracular gill-slit. Of particular importance are the descriptions by him and other workers of a large hyomandibula in the Rhenanida[6,7], and in at least one of the Ptyctodontida (*Rhynchodontus eximius* Jaekel)[8]. Doubt still exists about the interpretation of the visceral skeleton of the Acanthodii, and Holmgren[2] and Stensiö[3] have tried to show that these fishes are not aphetohyoid. The former's arguments are based to some extent on the assumption that acanthodians are an early branch of the selachian stock; the latter's evidence rests on the supposed course of the nerve fibres supplying what is believed to be the homologue of the actinopterygian preopercular neuromast line (see also Jarvik[5]).

It is only in the Carboniferous and Lower Permian genus *Acanthodes* that the acanthodian visceral skeleton is adequately known. However, even here discussions about its organization have been hindered by uncertainties over the structure of certain crucial regions, and by the often conflicting accounts of earlier workers[1,9,10]. I have studied a large number (about 50) of excellent, negatively prepared specimens of *Acanthodes bronni* Ag., and have been led to a partly new interpretation of the organization of the acanthodian head. This study may also throw some light on the relationships of the Acanthodii to the other classes of gnathostome fishes.

There is a series of four post-hyoidean branchial arches in *Acanthodes*, and the skeleton of the first, glossopharyngeal innervated arch, is structurally quite typical of the whole (Fig. 1). Dorsally it consists of a proportionately small epibranchial element which articulates against an infrapharyngobranchial of similar size. The latter element bears a stout, postero-dorsally directed process, against which a small suprapharyngobranchial articulates. In contrast, the hyoid arch consists, dorsally, of two elements. In all probability they were joined in life by cartilage (Fig. 1*B*), to form a large, continuous structure, which may be regarded as a hyomandibula. It lies in a broad groove on the mesial surface of the palatoquadrate (Fig. 1*A*). As the relationship of the latter to the neural endocranium is definitely fixed, through the articulation of the external otic process and basal process with the postorbital process and basipterygoid process respectively (Fig. 1 *B*, *C*), the position occupied in the head by the hyomandibula can be determined. It articulates with the neural endocranium just behind the postorbital process

* Present address: Department of Geology, Royal Scottish Museum, Edinburgh.

and plays an important part in the suspension of the upper jaw.

The large, ventral component of the hyomandibula is undoubtedly the epihyal. The nature of the small, dorsal component is less obvious. Earlier workers[2,10,11] have regarded it as the pharyngohyal (presumably the suprapharyngohyal in modern terminology), but as the hyomandibula articulates against the endocranium dorsally and laterally to the jugular vein, as in actinopterygians, this is not a completely satisfactory explanation. Further, because of the position of the jugular vein, it is very likely that both the infrapharyngohyal and suprapharyngohyal elements are incorporated in the brain-case as in crossopterygians, actinopterygians and elasmobranchs[12,13]. In actinopterygians, the hyomandibula is composed of the fused epihyal and laterohyal elements[13], the latter forming the articular head and being derived from hyoid gill ray material. Probably the dorsal element in the *Acanthodes* hyomandibula is equivalent to the actinopterygian laterohyal, so that the hyomandibula as a whole is of the same nature in the two cases. In elasmobranchs the hyomandibula appears to be formed from the epihyal only[14]; in the Batoidei, hyoid gill ray material may form the pseudohyoid[15].

Some previous writers[6,16,17,19] have independently compared the anterior basal element of the *Acanthodes* brain-case with the parasphenoid of other gnathostomes. It is clearly not a purely dermal formation[18], however, as it includes the basipterygoid processes and the base of the interorbital wall. What is important is that in this structure there can be recognized, at each side, anterior and posterior ascending processes, and a shallow sulcus which is identifiable as the spiracular groove. There is a marked correspondence in gross morphology between the anterior basal of *Acanthodes* and the parasphenoid of early actinopterygians (Fig. 2, ref. 12): and the spatial relationships of the structure in general, and at each side, its ascending processes and spiracular groove in particular, to the hypophysis, basipterygoid process, postorbital process and articular area for the hyomandibula, are exactly the same in the two cases (compare Figs. 1 and 2).

The spiracular groove in *Acanthodes* must have contained the spiracular tube, that is, the reduced dorsal part of the spiracular gill-slit, as is the case, for example, in *Amia* and other bony fishes[12,20]. This part of the spiracular gill-slit was therefore far removed from the hyomandibula (as in bony fishes), and it is quite evident that a normally functioning gill-slit did not exist between the mandibular and hyoid arches. Further, it has been shown above that the hyoid arch skeleton is highly modified in comparison with a typical branchial arch and plays an important part in the suspension of the upper jaw. It is very probable that the ventral half of the spiracular gill-slit was closed, as I hope to discuss on another occasion. The ceratohyal and hypohyal elements lie close to Meckel's cartilage and, as assumed by Jarvik[5], it is likely that the ramus mandibularis internus VII (the post-trematic branch of the n. facialis) was situated in the normal gnathostome (pre-trematic) position on the

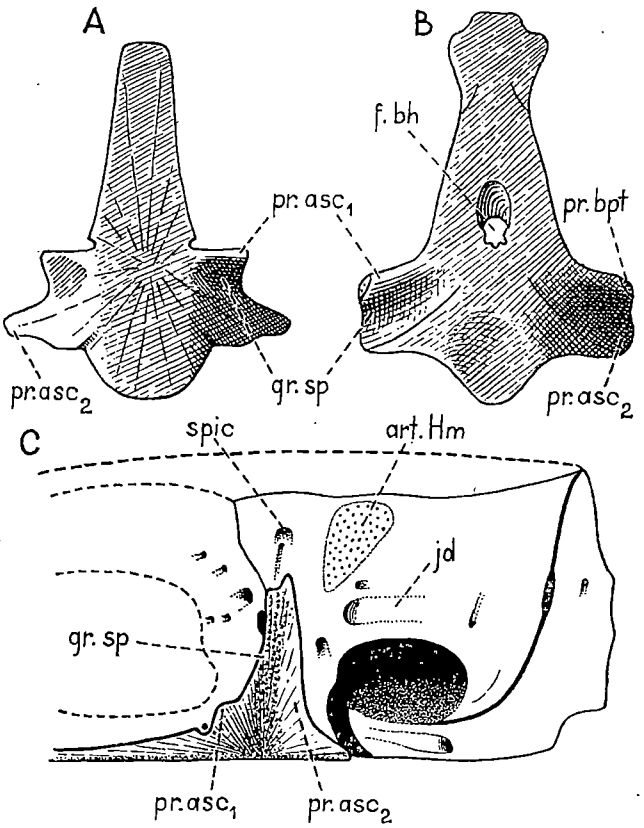

Fig. 2. *A*, *Pteronisculus magnus* (Nielsen) (Actinopterygii; Palaeonisciidae); parasphenoid in ventral view, teeth omitted; from Nielsen[20]. *B*, *Acanthodes bronni* AG.; anterior basal element in ventral view. *C*, *Pteronisculus cicatrosus* White; neural endocranium in lateral view; from Jarvik[12]. *art.Hm*, articular area for hyomandibula; *f.bh*, buccohypophysial foramen; *gr.sp*, spiracular groove; *jd*, groove for jugular vein; $pr.asc_1$, $pr.asc_2$, anterior and posterior ascending process, respectively; *pr.bpt*, basipterygoid process; *spic*, spiracular canal

mesial side of Meckel's cartilage[14]. The inescapable conclusion is that *Acanthodes* is not aphetohyoid, but is broadly the same as actinopterygians, crossopterygians and elasmobranchs in the general organization of the known regions of the head.

There remains for notation the gill-rakers that are found in *Acanthodes*. In the hyoid arch they are situated on the ceratohyal and hypohyal elements and on the epihyal part of the hyomandibula. They play an important part in Watson's arguments for the aphetohyoid condition. However, as Holmgren[2] has pointed out, gill-rakers are commonly present on the hyoid arch in present-day fishes in which the spiracular gill-slit is largely or completely closed, so their presence on this arch cannot be taken as evidence to show that the preceding gill-slit is complete and functional. It appears to me that the gill-rakers on the hyoid arch in *Acanthodes* project into the pharynx, and are associated with the presence of a large hyoidean hemibranch.

It is important to consider how far the conditions described for *Acanthodes* apply to the Acanthodii as a whole. It seems certain that *Acanthodes* is fully representative of the Acanthodiformes[21] (with the families Mesacanthidae, Cheiracanthidae and Acanthodidae) and Ischnacanthiformes, because of what is known of the palatoquadrate in the members of these groups; but there is little direct evidence about the nature of the visceral skeleton in the Climatiiformes (Climatiidae, Euthacanthidae and Diplacanthidae). Watson assumed that members of the latter group were aphetohyoid because he believed that his evidence showed that the main gill cover was carried on the mandibular arch. In the Acanthodiformes, however, it is clear from the relationship of the main, branchiostegal[5] (mandibular[1]) ray-bearing gill cover to the hyoid arch that it is hyoidean in nature, and I believe this to be true of all acanthodians (compare refs. 3–5). I find a marked lack of evidence for the view that any of the Acanthodii are aphetohyoid.

Nielsen[22] has pointed to some resemblances in the morphology of the palatoquadrate and endocranium between early actinopterygians and acanthodians (as represented by *Acanthodes*). His comparisons can be greatly extended in view of what has been outlined here, and we may also note the similar organization of the branchial arches with, for example, elongated hypobranchials, and the presence of large otoliths in acanthodians[1,23] (see also Heyler[24]). The Acanthodii seem to resemble palæoniscoid actinopterygians more closely than they do any other group of fishes, although the significance of this resemblance cannot yet be stated. Very large differences exist between the known members of these groups, particularly in the presence of body spines and the development of the shoulder-girdle. It is now clear that the Acanthodii have no important characters which serve to link them with the Elasmobranchii or Placodermi. In my opinion, these three groups are best ranked as separate classes of gnathostome vertebrates, along with the several classes of 'bony fishes'.

I thank Prof. E. Jarvik for the hospitality of the department in which this study was made, Mrs. M. Liepina for drawing the text-figures, and Dr. H. Jaeger and Prof. H. K. Erben for the loan of material. This work was supported by a NATO research fellowship.

SYNTHESIS OF NUCLEIC ACIDS IN *Opalina ranarum* Ehrbg.

By V. K. NILOVA and K. M. SUKHANOVA

Laboratory of Cell Morphology and Laboratory of Unicellular Organisms, Institute of Cytology, Academy of Sciences of the U.S.S.R., Leningrad

THE opalinids are multinucleate, homocaryote Protozoa. The great majority of *Protoopalina* and *Zelleriella* are binucleate. The genera *Cepedea* and *Opalina* are multinucleate. The trophonts of *Opalina ranarum* commonly possess about 200 nuclei. The division of the nuclei is asynchronous and does not appear to be in keeping with the division of the cytoplasm. In spring, during the breeding season of amphibians, the plasmotomy proceeds quickly, resulting in the formation of small individuals or tomonts[1] which are capable of encysting. The tomonts are formed by plasmotomy which usually does not correspond to nuclear division.

The life-cycle and morphological and cytochemical peculiarities of the opalinids have been examined thoroughly[1–5]. These investigations form the basis for the present experimental work which is devoted to the examination of some regularities of DNA and RNA synthesis in the trophonts of *Opalina ranarum* during different seasons.

Experiments were carried out on the natural populations of *Opalina ranarum* isolated from the intestine of *Rana temporaria* L. After isolation the opalines were placed in small test-tubes which are generally used for *Opalina* cultures *in vitro*[4]. Ringer's solution for amphibians was used as the medium for the control cultures. Ringer's solution previously injected with radioactive precursors of DNA and RNA served as the medium for the test cultures.

Tritiated thymidine (from the Radiochemical Centre, Amersham, Buckinghamshire, England) with a specific activity of 2·4 c./mM was diluted with distilled water to 100 mc./ml. Then Ringer's solution was added to it so as to reduce the final concentration of tritiated thymidine to 20 mc./ml.

^{14}C-Adenine (from the State Office 'Isotop', Moscow, U.S.S.R.) with a specific activity of 9 mc./ml. was diluted

with Ringer's solution to a final concentration of 1 mc./ml.

The opalines were incubated in the solutions injected with tritiated thymidine and ^{14}C-adenine for 1, 3, 24 or 72 h. After incubation, the opalines were fixed in Carnoy's solution, embedded in paraffin, and the sections were cut at 5μ.

The investigation was carried out by means of autoradiography on a liquid emulsion of '*R*' type supplied by the NIKFI, Moscow, U.S.S.R. The emulsion was applied to the sections by the method described earlier[5]. The sections with the emulsion were exposed for 20 days. Prior to the application of the emulsion some of the sections were treated with trichloroacetic acid, and some of the sections were treated by ribonuclease in the experiments with ^{14}C-adenine. The rest of the sections were stained with methyl green-pyronine. The control sections to which the emulsion had not been applied were stained by Feulgen, with methyl green-pyronine and hæmatoxylin-eosin. The index (percentage) of labelled nuclei was calculated on the basis of the examination of 1,000 nuclei, and more than 50 sections.

In winter and in spring, during the breeding season of the frogs, the opalines were incubated in the medium containing tritiated thymidine and ^{14}C-adenine within 3–14 days at 4° C, and within 1–72 h at 15° C. No labelled nuclei were found in opalines after their incubation in the medium containing tritiated thymidine. On the contrary, the label was obtained in some of the nuclei and in the endoplasm of opalines incubated in the medium with ^{14}C-adenine. After 72 h of incubation 19 per cent of the nuclei proved to be labelled. The label completely disappeared after treatment of the sections with ribonuclease. Thus, the label of both the nuclei and the endoplasm depended on RNA. The nuclei on the sections stained by Feulgen did not reveal any labelling at all, and this fact confirmed the result obtained in the experiments with tritiated thymidine.

^{14}C-Adenine was used for the examination of DNA and RNA synthesis in *Opalina* trophonts during the summer. The opalines were incubated in the medium containing ^{14}C-adenine for 1–72 h at 15° C. The label was obtained in some of the nuclei and in the endoplasm of each trophont in all the cases of incubation. The percentage of the labelled nuclei depended on the time of incubation of the opalines in the radioactive medium. The number of labelled nuclei increased very quickly after 1 h incubation and achieved a maximum after 3 h incubation (52·24 per cent). After 3 h the number of labelled nuclei began increasing slowly and after 72 h incubation only about 60 per cent of the nuclei appeared to be labelled (Fig. 1). Some of these sections were treated with ribonuclease. This treatment confirmed that 42·78 per cent of the nuclei possessed the label showing the RNA synthesis (this label disappeared after the treatment). The treatment also showed that the label did not disappear in 16·72 per cent of the nuclei. It could be assumed that synthesis of DNA occurred in these nuclei (Fig. 1) and this supposition was confirmed by examination of the sections stained by Feulgen. The nuclear and endoplasmic label completely disappeared after treatment with trichloroacetic acid.

The nuclei labelled with ^{14}C-adenine as a rule possessed small nucleoli, rather dense nuclear substance, and their diameter was about 6–6·5μ. No labels were observed in the nuclei immediately after their division. These nuclei are usually situated very closely to each other and their diameter was about 3–4μ. No labels were found in nuclei with large nucleoli and vacuoles, with a diameter of about 7·5–8μ. This kind of nuclei is usually characteristic of the majority of the nuclei in opalines during winter.

When comparing the results obtained, it can be seen that the nuclei of *Opalina ranarum* do not synthesize DNA either during winter or in early spring. At the beginning

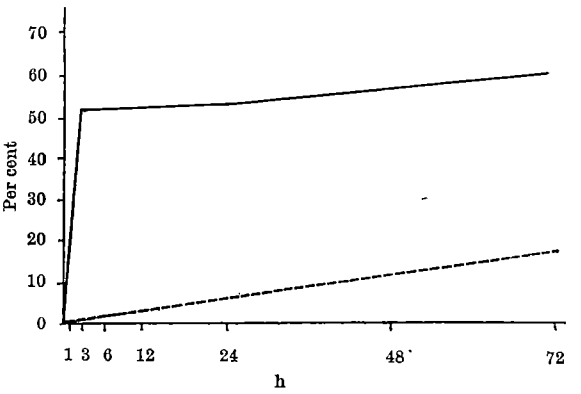

Fig. 1. The number of labelled nuclei in *Opalina ranarum* during various periods of incubation in the medium containing ^{14}C-adenine. The abscissa shows the time of incubation (h). The ordinate shows the percentage of labelled nuclei. The continuous line demonstrates the whole number of labelled nuclei; the dotted line—the percentage of labelled nuclei after the ribonuclease treatment

of spring many *Opalina* trophonts undergo a series of rapid divisions without compensatory growth. These plasmotomic processes result in the formation of pre-cysting forms and cysts containing several nuclei. Such plasmotomy which usually does not correlate with nuclear division is characteristic of opalinids and essentially differs from typical processes of palintomy[5] and syntomy. It can also be supposed that the processes of cyst formation proceed without DNA synthesis in opalines.

The results of the experiments with the incubation of the opalines in the medium containing ^{14}C-adenine show that RNA synthesis can be supposed to proceed all through the winter and spring as well. Approximately one-fifth of the nuclei of each trophont synthesize RNA during these seasons. It was important to establish that the number of the nuclei synthesizing RNA increased in summer and 42·78 per cent of the nuclei of trophonts took part in this process during summer.

Synthesis of DNA was observed in the nuclei of trophonts only in summer. This fact may suggest that *Opalina* cells synthesize the necessary storage of DNA during the summer period of the life-cycle when the Protozoa and their hosts are active. It is in summer that the intensive processes of DNA and RNA synthesis can be observed in the nuclei and in the endoplasm of the opalinids, and besides, many trophonts and their nuclei usually divide during this period of time. Thus, seasonal changes can be observed in the synthesis of DNA and RNA in *Opalina ranarum*.

The experimental results obtained also testify to asynchronism of both DNA and RNA synthesis (within the intervals investigated). The asynchronism in DNA and RNA synthesis can be confirmed by the observations of the label only in some of the nuclei of *Opalina ranarum* in summer, spring and winter as well. This observation allows us to suppose that only the labelled nuclei can synthesize DNA and RNA. Another confirmation of asynchronism of DNA and RNA synthesis in the nuclei of *Opalina ranarum* is the increase of the number of labelled nuclei during different periods of incubation of the trophonts in the radioactive medium (Fig. 1). 100 per cent labelled nuclei were not observed in any cases of incubation of the opalines, though the time of incubation was long enough for each nucleus to be labelled. Hence, the multinuclear cell of *Opalina ranarum* shows not only asynchronism in the nuclear division, but also asynchronic synthesis of DNA and RNA.

LETTERS TO THE EDITOR

ASTRONOMY

Lunar Erosion and Brownian Motion

RECENT photographs of the lunar surface taken by the U.S. *Ranger* space craft indicate that erosion occurs on the face of the Moon. A number of speculations as to the source of this erosion have appeared. I suggest that Brownian motion provides a mechanism of lunar erosion which seems likely to account for at least part of the observed erosion.

The face of the Moon is subjected to high-velocity impact by meteorites. Optical microscopic observations of rocks (for example, calcite) which have been fractured by high-velocity projectiles (bullets) have shown that a few large chips are produced by impact and that the material along the boundaries of these chips is pulverized into very fine particles which can barely be distinguished at times 850. The typical size of these particles seems to be about $10^{-1}\mu$, and one might expect the surface of the Moon to be covered with rock fragments of similar size. In addition, satellite data indicate that the typical diameter of micrometeorites is in the micron and sub-micron range (J. Mar, private communication, 1964), which further indicates that the dust cover of the Moon might well consist of rock fragments of about $10^{-1}\mu$ diameter. These small rock fragments should have a specific gravity of about 3·3 (the mean specific gravity of the Moon) and their weight in the gravity field at the surface of the Moon (which is about 0·16 times the gravity field at the surface of the Earth) should be about $0{\cdot}53 \times 10^{-12}$ dynes. The temperature on the sunny side of the Moon is of the order of 10^3 °K, and thus the value of kT (Boltzmann's constant, $k \simeq 1{\cdot}4 \times 10^{-16}$ dyne·cm/ °K) on the sunny portion of the lunar surface is about $3/2 \times 10^{-13}$ dyne·cm. Using these values of mg and kT in the barometric formula, one finds that the typical scale of height of the dust cloud on the moon (kT/mg) is roughly 3/10 cm. The density of the dust cloud is 1 per cent of its density on the surface at a height of about four times this typical scale (for example, four 'relaxation distances'), and so the height of the dust atmosphere on the sunny portion of the lunar surface is of the order of a centimetre. As the Moon turns and each portion of the lunar surface is alternately heated by the Sun for about two weeks and then cooled to low temperatures by radiation into space, the dust cloud rises and falls with about a 28-day period. The rising and falling of the dust cloud are accompanied by a redistribution of the dust which should gradually obscure the sharp features on the Moon, and thus provide a partial explanation for the observed lunar erosion.

In addition, the sharp edge of a lunar crater will cast a shadow in which the lunar surface will be cooled rapidly by radiation into space and heated rather slowly by conduction through surrounding material. The temperature of the surface in these shadows should be quite low, causing the dust cloud to fall locally. The dust cloud on the hot sunny side of a ridge will be drawn over the ridge to condense on the shadowy portion, and thus a second mechanism of erosion obtains. Since the mean kinetic energy of the dust particles is $3/2kT$, the mean velocity of those dust particles in the sun is about 10 cm/sec; this should be about the speed at which the dust flows over the tops of ridges in passing from the hot sunny side into the cold shadows where the dust cloud is almost completely condensed. The flow of these fine abrasive fragments should wear down the sharp ridges and thus contribute to the erosion observed in the *Ranger* photographs.

I note that even if the typical diameter of fine rock dust on the Moon were as large as a micron (and this seems unlikely), the height of the dust cloud on the sunny portion of the lunar surface would be of the order 10^{-3} cm (about 10 particle diameters) and the two mechanisms of erosion given here would still operate, although at a much slower rate.

GEOPHYSICS

Rocket Optical Observation of a Day-time Aurora

STUDIES of the day-time aurora have been restricted almost entirely to investigations by radio techniques. So far as we are aware the only published optical work is that by Noxon[1] on the red and green lines of atomic oxygen. In this communication we report the preliminary results of an investigation of the spectral region 4000–5900 Å obtained during a day-time aurora by means of a rocket probe launched from Fort Churchill, Manitoba, Canada.

The principal difficulty in an optical study of the day-time aurora is, very simply, that of knowing when an optical aurora is, in fact, present. Statistical investigations indicate some correlation between the radio and visual aurora but the correspondence is certainly not one-to-one. Furthermore, we must bear in mind that these investigations are based on night-time measurements and the situation may be different for day-time events. A second difficulty, of particular importance for rocket measurements, arises from the fact that the aurora in the auroral zone is normally quite limited in spatial extent and exhibits both rapid spatial movements and rapid intensity fluctuations. It is, consequently, fairly easy to fire a rocket at an aurora and find the aurora no longer there when the rocket reaches the altitude at which measurements begin.

Montbriand (private communication) has examined the statistical relationship between auroral absorption, as observed by the riometer, and visual auroral forms in northern latitudes. He has found that almost all the occurrences which take place (*a*) during the morning maxima between 0600 h and 0900 h, and (*b*) during which night conditions were still present, were associated with widespread diffused auroral glows. Such glows occasionally have active rays, patches and diffused surfaces within them.

As a result of the foregoing considerations the following criteria were used to decide whether the rocket should be fired: (1) the existence of moderate to strong magnetic activity; (2) the firing to be between 0600 and 0900 h; (3) riometer absorption greater than 0·5 dB; (4) increased absorption as shown by an appreciable increase in the ionosonde f_{min}; and (5) as a secondary criterion the presence of radio auroral echoes observed from the Prince Albert, Saskatchewan, radar facility. These criteria were met on the morning of July 18, 1964, and the launching took place at 0622 C.S.T. Due to technical difficulties, the firing was not at the maximum of the auroral event. Fig. 1 shows a portion of the 30 mc/s riometer record during this period. The flight times are indicated in Fig. 1. The instrument flown was a

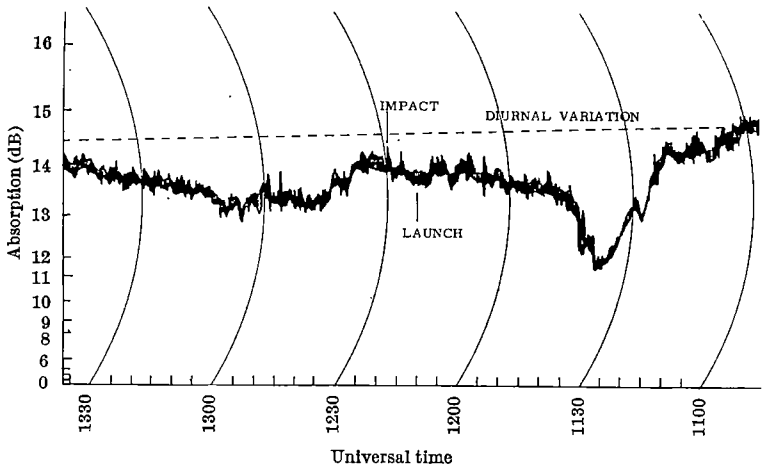

Fig. 1. Riometer absorption at Fort Churchill, Canada, from about 1100–1330 h U.T. on July 18, 1964. The estimated normal diurnal variation is indicated by a dotted line. The times of launch and impact of the rocket are indicated on the chart

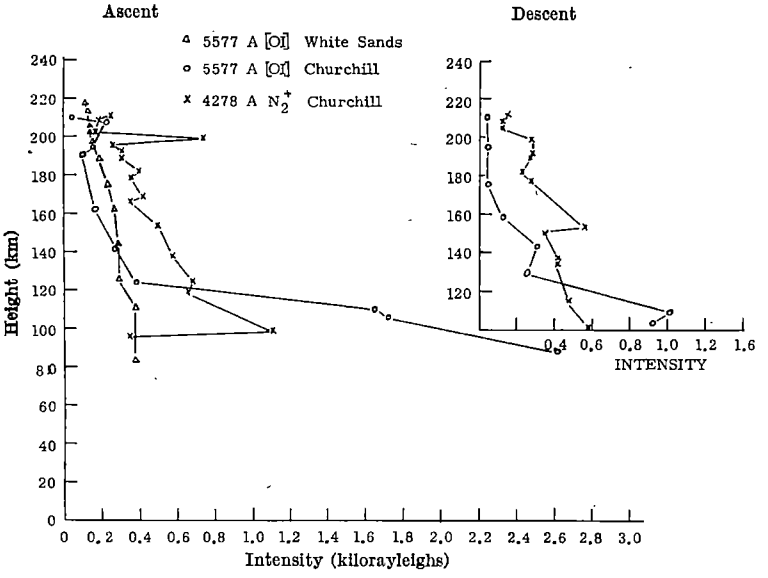

Fig. 2. Intensity variation with altitude for 4278 Å N_2^+ and 5577 Å [OI] at Fort Churchill, Canada, for July 18, 1964, compared with that for 5577 Å [OI] obtained at White Sands Missile Range, New Mexico, November 13, 1963. The intensity scale for the descent data has been displaced to avoid confusion

1-m Ebert spectrophotometer[2] with fixed slits set for a resolution of 11 Å and scanning the wave-length range 4000–5900 Å in 7 sec. The instrumental field of view was directed along the longitudinal axis of the rocket and viewed the sky through an opening exposed by the ejection of the nose cone tip. A 14-in. baffle and sun shade was mounted in front of the input slit to minimize the sunlight scattered into the instrument. The altitude of the rocket was determined by the use of a cosmic ray altimeter.

Preliminary analysis of the data leads to the following results. Because of scattered sunlight only two lines were unambiguously observed in the spectra: 5577 Å [OI] and 4278 Å N_2^+. The variation of the intensities, uncorrected for aspect, of these two lines with height is shown in Fig. 2. Also shown in Fig. 2 are the intensities of the 5577 Å line obtained from a rocket launched at 1600 M.S.T. on November 13, 1963, from White Sands, New Mexico. The same instrument, with a different grating and slit width, was used for the two flights, so that a fairly direct comparison of intensities as a function of height can be made. This comparison leads to the following conclusions: the optical day-time aurora is clearly evident in the lowest scans as a considerably greater luminosity at Churchill than at White Sands. The intensity of the 5577 Å line on the lowest altitude scan, that is, that which would be most comparable with a ground-based observation, is in the range to be expected for an I.B.C. I aurora. It is also of the same order as that reported during a part of the day-time aurora observed by Noxon[1]. We consider the height at which the luminosities are approximately equal at the two sites to represent the upper border of the aurora: Using data from both ascent and descent we determine the upper border as lying between 113 and 123 km, similar to a typical night-time aurora. The lower border cannot be determined from our data. Above 123 km the relative intensities are comparable in magnitude though they appear to fall off more rapidly with altitude at Churchill than at White Sands. This may be due to the difference in latitude, time of day, or to the presence of an auroral component even at the higher altitudes. It is difficult at present to determine which of these factors is responsible, though the descent data down to about 160 km indicate that the day-glow component at Churchill may be appreciably lower than the day-glow at White Sands. The 4278 Å N_2^+ band intensity appears to be due to particle bombardment, superimposed. The ratio of 4278 Å intensity to that at 5577 Å above 150 km is comparable to that reported by Wallace and Nidey[3] for the day-glow at White Sands. Thus we conclude that above about 120 km the optical observations refer primarily to a day-glow component and that the aurora is confined primarily to heights lower than this. Unfortunately no data on the ratio of these two lines for the normal day-glow below 150 km are available for comparison with the results of the present flight. The results reported here come from a preliminary analysis of the data.

OCEANOGRAPHY

Scavenging of 'Dissolved' Organic Matter from Sea-water with Hydrated Metal Oxides

In an effort to recover the 'dissolved'* organic matter from large volumes of sea-water by a simple and widely applicable process, co-precipitation experiments with hydrated metal oxides were undertaken using natural sea-water.

Previously published reports on the scavenging or co-precipitation of organic matter from sea-water had indicated that such an approach might be fruitful. Recoveries of organic compounds of the order of 80–100 per cent have been claimed. Jeffrey and Hood[1] co-precipitated the organic matter from a ^{14}C-labelled, aged algal culture filtrate by increasing the *p*H to 10 to precipitate $CaCO_3$ and $Mg(OH)_2$ from the sea-water. This scavenged 79 per cent of the ^{14}C-labelled material. They recovered 95 per cent of the labelled organic matter from the aged culture

* 'Dissolved' is arbitrarily defined as that passing a 0·45μ *HA* 'Millipore' membrane filter unless otherwise noted.

[1] All surface samples from the Scripps Institute of Oceanography pier except where indicated. The variable initial carbon is a result of sampling at different times.

[2] Metal as Fe^{3+}, Mn^{2+}, Cu^{2+} and Al^{3+}.

[3] Mean of duplicate samples. The precision of the method is ± 0·12 mg C/l. at the 95 per cent confidence limit.

[4] Surface water collected 5 miles offshore.

[5] Collected 85 miles offshore at a depth of 1,500 m.

[6] Sample centrifuged for 10 min at 2,000 r.p.m. in a clinical centrifuge after the settling time indicated.

by co-precipitation with $Fe(OH)_3$ at a *p*H of 7·6–8·21. The concentration of ferric iron used was 5·6 g Fe^{3+}/l. Tatsumoto *et al.*[2] and Park *et al.*[3] co-precipitated combined and free amino-acids from natural sea-water with $Fe(OH)_3$ (124 mg Fe^{3+}/l.) and Williams[4] recovered 0·1 mg C/l. of organic acids from deep sea-water by $Fe(OH)_3$ scavenging using 20 mg of Fe^{3+}/l. The addition of known organic compounds to sea-water in concentrations greater than those expected under natural conditions, and subsequent co-precipitation with $Fe(OH)_3$, yielded recoveries of polypeptides, organic acids, sugars and amino-acids ranging from 0 to 100 per cent (Williams[5] and Tatsumoto *et al.*[2]). In addition, Bader *et al.*[6] demonstrated scavenging of various organic compounds added to sea-water by the minerals montmorillonite and kaolinite.

In all the above cases, total organic carbon data for the sea-water were lacking. Menzel and Vaccaro[7] have recently developed a rapid and sensitive method for the determination of total organic carbon in sea-water, and this analysis has been used in the present work to assess the percentage removal of the dissolved organic carbon in sea-water samples by co-precipitation with $MnO_2.nH_2O$, $Fe_2O_3.nH_2O$, $Al_2O_3.nH_2O$, and $CuO.nH_2O$. These values are compared with the percentage adsorption of organic carbon by filter pads of activated alumina, a celite–MgO mixture and silicic acid.

The sea-water samples were collected from the Scripps Institution of Oceanography pier, from 5 miles offshore, and from a depth of 1,500 m at a station 85 miles offshore. Small samples were filtered immediately through an *HA* 'Millipore' filter, discarding the initial 200 ml. of filtrate, which contains a significant amount of organic matter leached from the filter. The 1,600- and 200-l. samples were filtered through a 35μ mesh-size net only. The samples were then acidified to *p*H 2 with organic carbon-free 6 N HCl. Iron, manganese, copper and aluminium were added as organic carbon-free solutions of $FeCl_3$, $MnSO_4$, $CuSO_4$ and $AlNH_4(SO_4)_2$. The 'Celite'–MgO mixture (1 : 1), activated alumina (neutral) and silicic acid were freed of organic matter by ignition at 450° C. The metal hydroxides were precipitated by the addition of 1 N KOH to give the desired final *p*H and allowed to settle. Organic carbon determinations were made on the initial filtered sea-water, the sea-water plus added metal at *p*H 2, the sea-water plus added metal and KOH at the final *p*H and on the supernatant liquid at time intervals thereafter, as the precipitates settled.

The organic carbon in the $Fe(OH)_3$ precipitate, after decanting the supernatant, was determined in two experiments and the carbon values checked to within 10 per cent of the values calculated from the initial and supernatant amounts. The solid adsorbers, approximately 25 g, were slurried in organic carbon-free distilled water, poured into the 'Millipore' filter assembly to form a pad 3 cm deep, through which 400 ml. of the filtered sea-water was passed; the initial 200 ml. of filtrate was discarded.

Table 1 summarizes the conditions and percentage removal of carbon by co-precipitation. Table 2 gives the carbon adsorbed by 'Celite'–MgO, alumina, and silicic acid.

The effect of the final *p*H on the percentage removal of organic matter was determined by precipitating 0·5 l. samples of sea-water (initially containing 1·26 mg C/l.) with 20 mg Fe^{3+}/l. at a final *p*H of 4, 5, 6 or 7. The percentage removal was 38, 44, 42 or 38 respectively. The percentage removal as a function of time was variable but, in general, the maximum amount was co-precipitated in 8 h and further standing did not significantly improve the yield.

Table 2. PERCENTAGE REMOVAL OF ORGANIC CARBON FROM SEA-WATER USING SOLID ADSORBANTS.

Adsorbant	Initial mg C/l.[1]	Final mg C/l.	Percentage removal
'Celite'-MgO	1·31	1·06	19
Silicic acid	1·31	1·01	23
Alumina	1·31	0·75	43

[1] The same sea-water was used in all three experiments.

The 200-l. samples were co-precipitated in a 220-l. polyethylene tank, and the 1,600-l. sample in a 1,900-l. polyvinylchloride-lined tank. All other precipitations were made in glass. There was no detectable organic carbon contamination from the reagents or from the polyvinylchloride liner. The use of the polyethylene tank gave an increase of 0·1 mg C/l.

It is evident from Table 1 that Fe^{3+} at a concentration of 20 mg/l. and at a final *p*H from 4 to 6 is the most effective scavenger of the systems studied. A five-fold increase in Fe^{3+} did not increase the yield, while a fifty-fold increase only gave an additional 12 per cent removal. This latter concentration gives cumbersome amounts of precipitate in dealing with large volumes of water. Centrifugation of the supernatant solution did not improve yields.

The amount of organic carbon scavenged from the five sea-water samples from the surface, collected at the pier, using 20 mg Fe^{3+}/l. and at a final *p*H of 5 to 6·4, ranged from 38 to 43 per cent, indicating that a relatively constant fraction of the organic matter was scavenged by $Fe(OH)_3$ from samples with variable initial levels of organic carbon. The low recovery from the 1,500-m sample was consistent with the hypothesis that deep-water organic matter has already been exposed to any indigenous clay mineral and

ferric hydroxide scavenging processes in the sea and thus contains less organic matter susceptible to further scavenging.

There may be a refractory compound or group of compounds in deep sea-water which are resistant to chemical and biochemical oxidation or utilization and which may be 'old' in the sense that the inorganic carbon in deep water is old relative to that in the surface water. This study was undertaken in the hope of isolating sufficient dissolved organic carbon from deep water to obtain an age using radiocarbon dating.

This work was sponsored by the United States Atomic Energy Commission, Contract *At*(11-1)-34, Project 108. *AEC* Ref. No. *UCSD*-34*P*-108-2.

Uranium Distribution in Drake Passage Waters

CONSIDERING the amount of work that has been done concerning the uranium content of oceanic waters, remarkably few data can be found for the Antarctic Ocean compared with the North Pacific, the North Atlantic and the Indian Oceans[1-5]. It is possible the Antarctic waters might have a considerable interchange with the deep waters of the Atlantic and the Pacific. Information about the distribution of uranium in Antarctic waters might, therefore, contribute significantly to knowledge of oceanic circulation.

Water samples were collected during a cruise (TRIDENTE-3, February–March 1963) by R/V *Capitan Canepa* of the Argentine Navy Hydrographic Service, along the transect of Drake Passage (Fig. 1). The microquantities of uranium present in the samples were determined fluorometrically by using fused mixture with sodium fluoride[6].

To each sample of 200–500 ml., 10 ml. of mixed solution of concentrated HNO_3, aluminium nitrate solution (50 mg/ml.) and ammonium hydrogen phosphate solution (12 mg/ml.), in the ratio of 3 : 2 : 5, was added. After boiling the sea-water for 10 min to decompose the carbonate anionic complex of uranium, aluminium phosphate was precipitated at *p*H 6 by adding ammonium hydroxide. Uranium was co-precipitated with the aluminium phosphate.

The precipitate-containing uranium was ignited at 450°–500° C. The residue was dissolved in 10 ml. of HNO_3-acidified aluminium nitrate (a solution contained 900 g of $Al(NO_3)_3 \cdot 9H_2O$ in 500 ml. of 1 : 10 HNO_3) as a solvent and salting-out agent.

Uranium was extracted with 10 ml. of ethylacetate, and a 2-ml. portion of ethylacetate solution was evaporated on a platinum dish (diameter 1·5 in.) moderately heated over a water-bath. To the residue on the platinum dish, 2 g of flux (fused and pulverized mixture of K_2CO_3, Na_2CO_3 and NaF with the ratio of 45·5 : 45·5 : 9) was added and fused for 20 min at 650° C in a specially designed double-rotating electric oven. The cake obtained from rapid cooling of the fused material was stored in a desiccator. The fluorescence was measured at a wave-length of 555 mμ with a transmission-type fluorometer[6]. The uranium content of reagents used for uranium determination were checked before the analysis. The results showed that the total blank was below 0·01 μg.

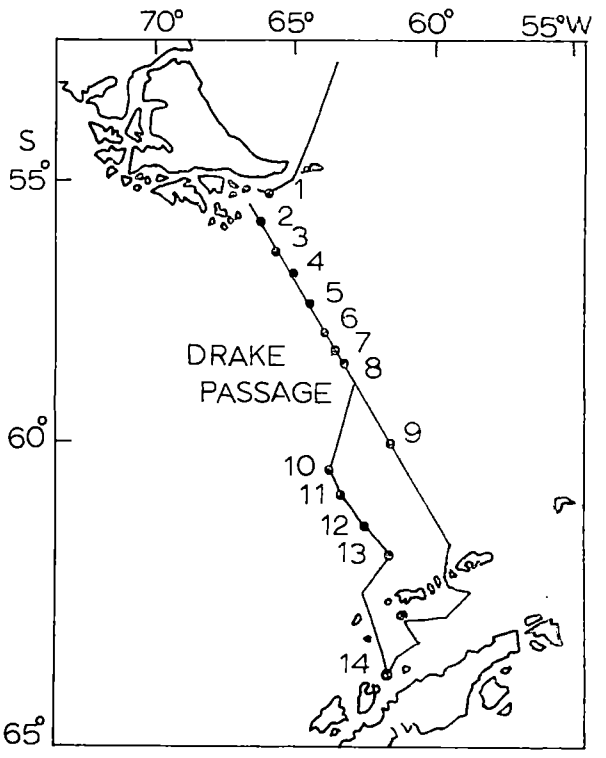

Fig. 1. Location of water sampled

The results of analyses of the surface waters are summarized in Table 1, and the vertical distribution of uranium for stations 8 and 9 is shown in Table 2. It can be seen that fairly constant values of uranium were obtained in the surface sample from elsewhere in Drake Passage. In this season, the Antarctic Convergence was located

B. Sampling site: 60° 00′ S., 61° 25′ W. (St. 9, March 10, 1963)

Depth (m)	Temp. (°C)	Salinity (‰)	Uranium ($\times 10^{-6}$ g/l.)
0	1·20	33·88	3·0 ± 0·03
180	0·72	34·23	3·1 ± 0·03
360	1·95	34·58	3·0 ± 0·03
770	1·99	34·60	3·2 ± 0·03
1,820	1·18	34·64	3·3 ± 0·03

between 58° S and 59° S. However, there was no significant difference in uranium content between the samples from both sides of the convergence.

Baranov and Khristianova gave an average value of $2{\cdot}7 \times 10^{-6}$ g/l. of uranium for the southern Indian Ocean[5]. Rona *et al.* and Wilson *et al.* gave an average of $3{\cdot}3 \times 10^{-6}$ g/l. of uranium for the North Atlantic and the North Pacific waters[1,2]. An average of $3{\cdot}4 \times 10^{-6}$ g/l. of uranium was given by Miyake and Sugimura for the western North Pacific waters off Japan[4]. For the uranium content of surface waters in Drake Passage, an average value of $3{\cdot}1 \pm 0{\cdot}2 \times 10^{-6}$ g/l. is obtained, which is in the same order of magnitude as those in previous work.

In its vertical distribution, uranium tends to show a minimum concentration about the depth of 300–400 m, increasing at greater depth. A similar vertical distribution of uranium was found by Miyake and Sugimura in the area of the western North Pacific[4].

METALLURGY

Austenite/Carbon Reaction in Cast Iron

In our experiments in collaboration with the British Cast Iron Research Association, on the gouging and machining of grey iron with a plasma jet, it came to our notice that the skin of the iron under the gouge had become white due to being heated close to or slightly above the melting point and rapidly cooled. Subsequent experiments have shown that, if we quickly passed the plasma jet over the surface of the iron so that it reached a high temperature (~1,100° C) but did not melt, a white surface layer was produced which in some cases contained graphite.

Fig. 1 shows the cementite/graphite surface layer. In the lower areas of the photomicrograph, cementite (white)

Fig. 1. Photomicrograph of the cementite/graphite surface layer (×100)

Fig. 2. Lower right-hand corner of Fig. 1 (×400)

can be seen growing out from graphite flakes. In these areas the thermal cycle has been such as to arrest the reaction. Fig. 2 is a photomicrograph of this particular area at higher magnification showing the cementite 'dendrites' in greater detail. The particular iron used contained 3·4 per cent carbon, 3·5 per cent silicon and 0·67 per cent manganese.

The mechanism of the production of this layer is probably that the rapid localized heating causes the formation of Fe_3C by reaction between the graphite and iron, and the rapid cooling retains the Fe_3C, giving it insufficient time to decompose back to iron and graphite. The surface layer comprising cementite and some graphite is hard (up to 1,000 Vickers pyramid number) and, with the added self-lubricating and oil-retaining effect of the graphite flakes, it should provide good wear resistance.

CRYSTALLOGRAPHY

Growth of Crystals from the Melt in Glass Tubes

The rates of growth of benzophenone and salol from the melt have been investigated. Single crystals were grown freely in the melt, and the rate of advance of a single face was measured by means of a travelling microscope. In further experiments the crystal faces were allowed to grow into glass capillary tubes which were situated in the melt normal to the face. The melts were held at constant under-coolings of 4° C or less, by means of a thermostat: under these conditions it was found that on entering the capillary the face remained plane but advanced down the tube at a rapidly diminishing rate, finally practically ceasing to grow altogether. The data on an experiment with the (100) face of salol are as follows:

Undercooling 3·6° C. Capillary 1·5 mm internal diameter.
Free growing rate was 25×10^{-5} cm s^{-1}
Average rate for 1st 5½ h in capillary $0{\cdot}87 \times 10^{-5}$ cm s^{-1}
Average rate between 52 and 92 h $0{\cdot}02 \times 10^{-5}$ cm s^{-1}

When a crystal face had ceased to grow inside a capillary it was found that on touching the face inside the capillary with a glass spike the face started to advance again, but at a rapidly diminishing rate, finally coming virtually to rest once more. For example, the (001) face of a benzophenone crystal was allowed to grow into a capillary of 1·5 mm internal diameter at an undercooling of 2·0° C. The free growth rate under these conditions is about

Time (min)	Growth rate (cm s^{-1}) × 10^5
0	0·2
34	0·1
34	touched surface inside capillary with glass spike
34½	11·9
40	4·6
45	2·1
50	0·9

The above growth rates were determined from the slope of the displacement/time curve).

20×10^{-5} cm s^{-1}. Growth measurements were then begun at a time when the rate had already fallen to a very low figure.

Most of the experiments were carried out in tubes of diameter 1·5 mm or less. In one experiment, however, the (010) (the slowest growing) face of a salol crystal was allowed to grow into a much wider tube of 0·8 cm internal diameter at an under-cooling of 2·2° C: the effect was similar although the retardation was somewhat less, the results being as follows.

Time (h)	Displacement (cm)	Rate (cm s^{-1}) × 10^5
0	0	6·7
⅛	0·04	
⅝	0·087	8·2
1⅝	0·382	

The crystal which had hitherto been free growing now entered the 0·8 cm diameter tube

2½	0·480	1·6
20	1·498	
67	2·886	0·18
96	3·074	
122	3·159	0·09
146	3·198	0·045

(The rates given are the average rates over the times indicated by the brackets)

Several different types of experiment were carried out with salol which convinced us that the observed retardation is not due to accumulation of impurities in the melt in advance of the growing face. No altogether satisfactory explanation of the observation has yet been found; but tentatively two alternative lines of approach are suggested. If growth layers were normally nucleated at the edges of faces, it seems possible that when the crystal grows into, and fills, a glass tube this nucleation process would be hindered or eliminated; this would explain the retardation on entering the tube. But it would also be necessary to assume that scratching the crystal surface with a glass spike would temporarily set up defects in the surface which would enable new layers to be nucleated at those defects, until such time as the defects are healed over or grow out to the walls.

Alternatively, growth layers may always be initiated at defects in the surface (which may be screw dislocations, groups of screw dislocations, or major defects such as grain boundaries). Then it would be necessary to assume that when growing in a tube these defects either grow out to the walls or are healed over. At the same time it would be necessary to assume that fresh defects are less easily formed in a crystal that is confined in a tube than in a free-growing crystal.

When growing in capillaries at under-coolings of greater than about 6° C the advancing faces were no longer plane, the crystals were no longer transparent and appeared to be polycrystalline; under these conditions the slowing up of growth was not observed.

The results presented here suggest that the measurement of growth rates in capillary tubes, on which much reliance has been placed in the past, is no guide to the behaviour of free-growing crystals.

CHEMISTRY

Adsorption of Krypton and Xenon on Evaporated Metal Films

Brennan *et al.*[1] quoted our earlier communication[2] in connexion with the determination of the effective cross-sectional areas of adsorbed xenon molecules, σ(Xe). However, a numerical error appears in their article. The values 13·8 and 17·2 Å² were not given in our communication and the value σ(Kr) = 19·5 Å² was not used as a reference value. Our communication indicated that we found from the measurements of xenon adsorption on evaporated nickel films at 78° K that σ(Xe) = 19·3 Å², and from measurements at 90° K that σ(Xe) = 21·8 Å². Moreover, σ(Kr) = 21 Å² was used as the reference value. The adsorbed amounts of xenon and krypton were always estimated by the same volumetric method and evaluated by means of the Brunauer–Emmett–Teller theory.

The value of the ratio σ(Xe)/σ(Kr) (xenon and krypton adsorption was measured at 78° K) was 0·92 in our communication, which is in good agreement with the value 0·95, which Brennan *et al.* calculated from their experimental data for the same system.

Catalysed Reaction of Xenon with Fluorine

Nickel reaction vessels have been used in the past for the preparation of xenon fluorides because of the good resistance of this metal to attack by fluorine[1–3]. However, despite the apparent ease with which these compounds form, the possibility that nickel may be acting as a catalyst has apparently been overlooked. To test this possibility we have carried out the following experiments.

Xenon (99–100 per cent, balance krypton) and fluorine (at its vapour pressure at −196° C) were mixed in a fused silica vessel. A nickel filament (0·020 cm diam.) was heated electrically in the gas mixture and its temperature monitored by following the resistance. Pressure changes in the vessel were followed with an all-metal bellows manometer. The results shown in Fig. 1 were obtained with the walls of the vessel cooled to −78° C. The number of molecules that reacted was determined from the pressure changes observed when the nickel wire was heated in the range 180°–400° C. The reaction is of zero order until about half the initial material has reacted, then slows down, and has almost stopped when two-thirds has reacted. The product condenses in the form of a fine white powder on the cooled walls of the reaction vessel. The composition of the gas phase at the end of an experiment was determined by freezing the xenon in liquid nitrogen and pumping the excess fluorine away.

The ratio of fluorine to xenon (F_2/Xe) reacted was reproducibly 1·2 and was independent of the temperature of reaction over the range examined and independent of the initial F_2/Xe ratio in the range 0·8–2·0. The product, on standing at room temperature in the evacuated vessel, decomposed over about one hour to give a total pressure corresponding to the amounts of xenon and fluorine reacted.

The Arrhenius plot of the reaction rates is shown in Fig. 2. From this is derived an activation energy of 10·4 kcal $mole^{-1}$ and a pre-exponential factor of $\sim 10^{21}$ molecules sec^{-1} cm^{-2}. This last-mentioned value is comparable with the collision frequency of xenon with the nickel wire.

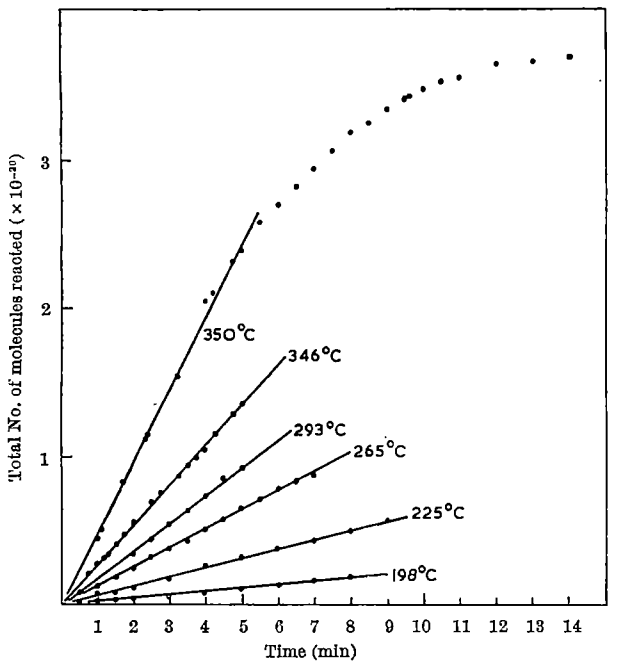

Fig. 1. Rate of reaction of xenon with fluorine at different temperatures

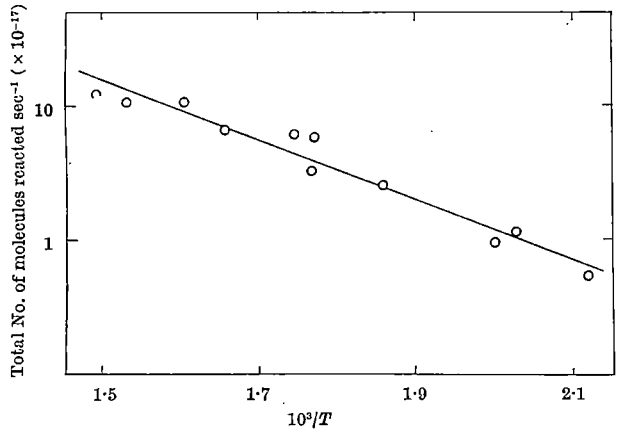

Fig. 2. Arrhenius plot for the reaction of xenon with fluorine

Reaction rates measured with the walls of the vessel at 0° C were lower and zero order conditions held over a much smaller extent of reaction (about one-quarter). This suggests that the product interferes with the reaction if it is not effectively frozen out. The product crystals, which condensed at 0° C, were larger than those condensed at −78° C, colourless, and could be readily sublimed.

Experiments in which xenon and fluorine were heated in the silica vessel in the absence of any hot metal surface and also in which fluorine alone was heated by the nickel filament showed that no reaction took place.

To compare the catalytic activity of nickel with other metals, similar experiments were carried out on copper, aluminium and platinum wires. In the temperature range examined for nickel these metals produced no measurable reaction. However, copper was effective above ~550° C with a rate corresponding to that observed at 200° C on nickel. Reaction occurred on aluminium from ~430° C up to its melting point; the rate at 450° C corresponded to the nickel rate at 200° C. In both cases a product was observed which behaved similarly to that formed in the nickel reaction. The interaction of fluorine alone with these metals under the reaction conditions was found to be small.

At about 510° C, platinum reacted vigorously to give a sharp drop in pressure. The walls of the vessel were covered with a pale yellow solid which hydrolysed on exposure to air. Addition of water to this material produced a yellow precipitate. The relative amounts of xenon, fluorine and platinum used up in the reaction were Xe : F : Pt = 2 : 12 : 1.

Electron-microscope examination of the nickel wire after reaction showed that the surface (×10,000) was roughened by polycrystalline flakes (~1μ), which were shown by electron diffraction to be composed of very small crystals of NiF_2. The surface of the copper wire was heavily encrusted with CuF and CuF_2. The aluminium surface was covered with crystals (0·2μ) of AlF_3.

The different activities observed for these metals show that the reaction between xenon and fluorine is catalysed by a nickel surface and to a lesser extent by copper and aluminium. The low activation energy measured is consistent with the ease of formation of these compounds and may be of interest when considering the energies involved in the formation of the xenon fluorides.

We thank Dr. T. A. O'Donnell of the Chemistry Department, University of Melbourne, for his advice. We also thank Mr. V. Sheludko for assistance with the experimental work.

New High-pressure Polymorphs of Sodium Bromide and Sodium Iodide

Recently new high-pressure polymorphs were discovered for sodium chloride[1] and sodium fluoride[2]. It is reasonable to expect the other sodium halides also to show polymorphism when subjected to elevated pressures. Bridgman[3] failed to find any evidence for polymorphism in the sodium halides.

Pressures up to 50 kbars were generated in a piston-cylinder apparatus similar to that previously described[4]. Possible transitions were investigated with the volume-discontinuity method[5]. The halides were dried at 300° C pre-pressed into a cylindrical pellet about 1 in. long and 0·5 in. in diam., and wrapped in thin lead foil. Piston displacement versus pressure was plotted. Temperatures up to 200° C could be obtained by wrapping a heavy-duty heating coil around the pressure vessel.

The curves obtained for sodium bromide showed a very sluggish but reversible transition near 11·5 ± 2·5 kbars at temperatures of 175°–200° C. At lower temperatures the transition did not occur at all. The kinetics of the transition appeared to be very similar to the kinetics of the corresponding transition in sodium chloride[6] and in some alkali fluorides[7].

No transition was found in sodium iodide at temperatures ranging up to 140° C, but at 164° C a transition was easily picked up at 10·2 ± 2·5 kbars. The transition was also found at 171° C, 11 ± 2·5 kbars, and 175° C, 11·6 ± 2·5 kbars. The sodium iodide transition is much less sluggish than the sodium bromide transition, and at 194° C, where the transition pressure is 14·0 ± 2·5 kbars, the transition was still running when the piston reached the end of its travel. The change in volume is at least 8 per cent, and may be much more. A fresh set-up was made to check these values and similar results were found. The best transition pressure obtained is 14·3 ± 1·5 kbars at 190° C, being the average of the readings obtained with increasing and with decreasing pressure.

Transitions have now been found for all the sodium halides at elevated pressures. The transition in sodium chloride is one from the sodium chloride-type structure

to the cæsium chloride-type structure[1], and it is to be expected that the transitions in sodium fluoride, bromide and iodide are similar.

Polymeric Structure of Mercury tert-Butyl Mercury Mercaptide

Investigations of metal alkoxides[1] have shown that polymeric molecules $[M(OR)_x]_n$ are generally formed unless the alkyl group (R) is bulky. Work on sulphur analogues known as metal mercaptides $M(SR)_x$ was undertaken in order to compare the structures and properties of metal alkoxides and metal mercaptides. A survey of the work on metal mercaptides showed that the lowest mercaptide, mercury methyl mercaptide $Hg(S{\cdot}CH_3)_2$, has quite a compact structure[2] having weak intermolecular Hg—S bonds. The structure is consistent with the high melting point (185°) and low solubility of this compound. The next higher mercaptide, mercury ethyl mercaptide $Hg(S{\cdot}Et)_2$, melts at a low temperature (76°) and as such has essentially a molecular structure[3]. The structures of most of the higher mercaptides are likely to be molecular since they are volatile and soluble in organic solvents. The properties of mercury *tert*-butyl mercaptide did not fit into this pattern. This compound has a low solubility and sublimes at a high temperature (135°) under low pressure. An X-ray analysis of this compound was, therefore, undertaken in order to elucidate its crystal structure.

Rotation and Weissenberg photographs (copper radiation) of the orthorhombic needles of the compound obtained by vacuum sublimation gave the following results: $a = 18{\cdot}36 \pm 0{\cdot}03$ Å, $b = 9{\cdot}18 \pm 0{\cdot}02$ Å, $c = 7{\cdot}52 \pm 0{\cdot}01$ Å; $d_{obs} = 1{\cdot}97$ g cm^{-3}, $d_{calc} = 1{\cdot}972$ g cm^{-3}; $z = 4$; space group $C222$. The $hk0$ and $h0l$ results were obtained and measured using multiple-film technique and visual estimation.

The ($hk0$) and ($h0l$) Patterson projections gave the co-ordinates for Hg_1, S_1 and S_2 and precluded the other two space-groups, namely, $Cmm2$ and $Cmmm$. Positions of the carbon atoms obtained by mercury–difference Fourier syntheses are less precise because of the presence of the heavy mercury atom in the crystal structure. The structure was refined by the successive difference Fourier syntheses and the final agreement index for all $hk0$ and $h00$ reflexions is 0·12. All calculations were made on the IBM 7040 computer using programmes written in *Fortran IV*, in this laboratory.

The results of the structure analysis of this compound are interesting. The structure of this compound is quite different from those of the other known mercaptides and consists of rows of mercury atoms (Hg—Hg = 3·76 ± 0·01 Å) parallel to the crystallographic C axis. Each mercury is surrounded by four sulphur atoms (Hg—S = 2·59 ± 0·025 Å, 2·66 ± 0·025 Å) in a highly distorted tetrahedral arrangement, angles SHgS being 87 ± 1·5°, 90 ± 1·5°, 121 ± 1·5°. A polymeric chain parallel to the C axis is formed by an infinite sharing of the opposite edges of the tetrahedra. The sulphur of the mercapto group acts as a bridge linking the two neighbouring atoms. The values of the Hg—S—Hg bridge angles are 90 ± 1·5° and 93 ± 1·5°. The dimensions of the chain are shown in Fig. 1. All chains are parallel to each other and to the C axis. The forces between the various chains are of residual type.

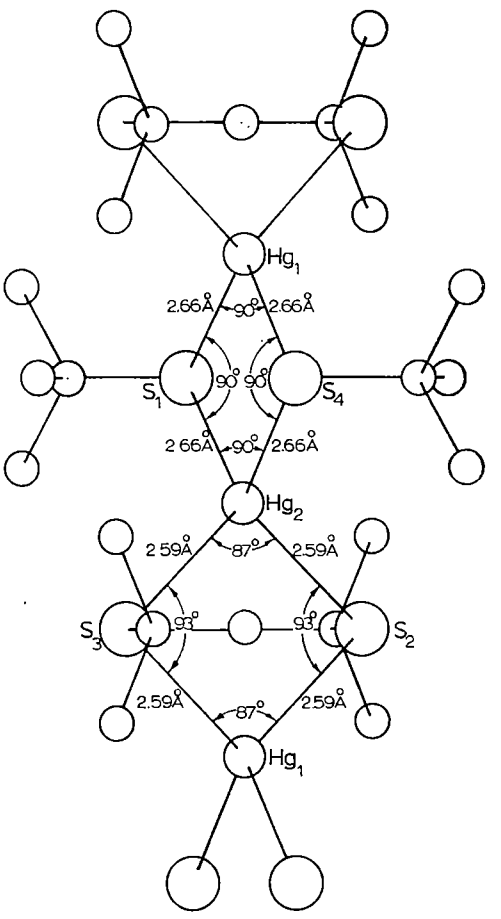

Fig. 1. Bond-lengths and bond-angles in the polymeric chain of mercury *tert*-butyl mercaptide

It is intriguing that this compound has a true polymeric structure while the lower mercaptides $Hg(S{\cdot}Met)_2$ and $Hg(S{\cdot}Et)_2$ have molecular structures. A probable explanation for this is that in all these compounds co-ordination occurs through sulphur, and in the case of sulphur, the greater the substitution, the greater is its co-ordinating power[4].

Optical Rotatory Power of DNA and of its Complex with Acridine Orange under Streaming Conditions

This communication reports the results of experiments in which left- and right-circularly polarized light is propagated along the flow lines of a streaming solution of DNA or of the DNA-AO (acridine orange (I)) complex, and the differential molar extinction coefficient ($\varepsilon_l - \varepsilon_r$) is measured as a function of wave-length. By these means circular dichroism bands due to electronic transitions polarized parallel and perpendicular to the helix

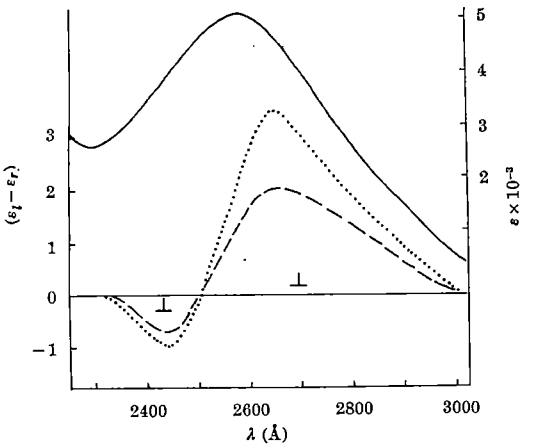

Fig. 1. The electronic absorption spectrum (———) and the circular dichroism (— — —) under stationary and (. . . . .) under flow conditions of calf-thymus DNA in aqueous solution at *p*H 6·5. ⊥, perpendicular polarization

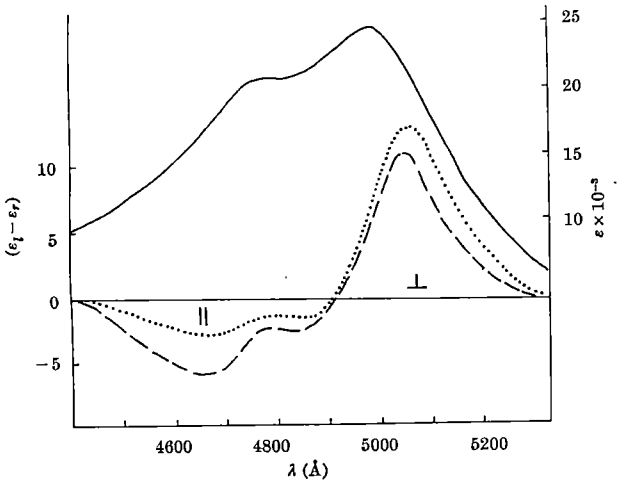

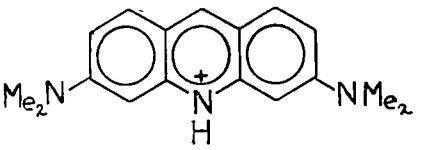

Fig. 2. The electronic absorption spectrum (———) and the circular dichroism (— — —) under stationary and (. . . .) under flow conditions of the DNA-acridine orange complex, with one dye molecule per base-pair, in aqueous solution at *p*H 6·5. ∥, parallel, and ⊥, perpendicular polarization

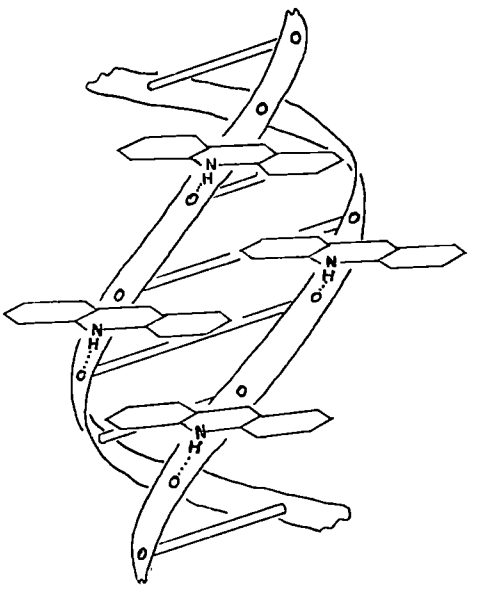
axis of the DNA polymer are distinguished, as light propagated along the helix axis can give rise only to transitions with perpendicular polarization. With the small flow rates employed (3 c.c./sec through a cylindrical cell 4 mm in diameter) the degree of orientation of the rod-like polymer molecules along the flow-lines is small, but it is sufficient to produce circular dichroism changes (Figs. 1 and 2) which allow the polarization directions of the bands to be identified.



The area of a circular dichroism band measures the rotational strength of the electronic transition responsible for the absorption. Current theories[1,2] of the optical rotatory power of helical polymers distinguish two types of rotational strength which are dependent on the pitch and on the radius of the helix, respectively. The rotational strengths of each type derived from a given monomer excitation sum to zero in principle, and in each case the observed circular dichroism should consist of two bands, or groups of bands, with equal areas and opposed sign. The two types differ, however, in that the pitch-dependent rotational strengths are associated only with perpendicularly-polarized transitions, whereas the radius-dependent rotational strengths derive from transitions which are polarized parallel and perpendicular to the helix axis of the polymer.

The results obtained for DNA show (Fig. 1) that both the circular dichroism[3] bands associated with the 2600 Å absorption increase in area under the flow conditions adopted, and that their rotational strengths are of the pitch-dependent type derived from perpendicularly polarized transitions. Accordingly the monomer excitations responsible for the measured optical rotatory power of DNA are the lowest-energy $\pi \rightarrow \pi^*$ transitions of the purine and pyrimidine base-pairs and not the $n \rightarrow \pi^*$ transitions[4], which have electric moments directed parallel to the helix axis in DNA. The magnetic moment of the $n \rightarrow \pi^*$ transition, directed in the molecular plane of the purine or pyrimidine base, may contribute to the rotatory power of DNA, however, as a non-zero rotational strength requires an electric and a magnetic transition moment which are either parallel or antiparallel.

Structures proposed for the DNA-AO complex are the intercalation model[5], in which each dye molecule (I) is sandwiched between two adjacent base-pairs, and the tangential stacking model[6], in which each dye molecule is held by an ionic bond between a dimethylamino group of (I) and a phosphate residue of DNA. In both models the molecular plane of the dye (I) is orientated perpendicular to the helix axis of the DNA, so that in the DNA-AO complex all $\pi \rightarrow \pi^*$ transitions of the dye should have a perpendicular polarization, and should give pitch-dependent rotational strengths only. However, the present flow experiments show (Fig. 2) that, of the two circular dichroism bands of the DNA-AO complex associated with the 5000 Å acridine orange (I) absorption, one is polarized parallel and the other perpendicular to the helix axis of the DNA, the band areas decreasing and increasing, respectively, on streaming. Accordingly these circular dichroism bands are due to radius-dependent rotational strengths, which require that the molecular plane of the dye (I) is orientated neither parallel nor perpendicular to the helix axis of DNA in the complex and that the super-helix of bound dye molecules has a non-zero radius. As the parallel-polarized circular dichroism band of the complex at 4670 Å has a negative rotational strength, the super-helix of bound dye molecules is left-handed, indicating that the dye molecules

(I)

(II)

are accommodated in neither the large nor the small groove of the right-handed sugar-phosphate helix of the DNA molecule. The perpendicular (5050 Å) and the parallel polarized (4670 Å) circular dichroism bands of the DNA-AO complex lie at wave-lengths (Fig. 2) where the unpolarized absorption is relatively strong and weak, respectively, suggesting that the long-axis of the dye molecules, which is the polarization direction of the 5000 Å $\pi \rightarrow \pi^*$ transition of the free dye (I), is orientated at an angle $90° > \alpha > 45°$ to the DNA helix axis in the complex.

The conclusions of the work recorded here suggest the structure (II) for the DNA-AO complex. The primary basic centre of acridine orange (I) is the nuclear nitrogen atom, which is bound in the complex (II) by an ionic or a hydrogen-bond to a phosphate residue of the DNA in such a manner that the long-axis of the dye molecule is inclined at an angle to both the helix axis and the sugar-phosphate strands of the DNA. Dispersion forces between dye molecules bound at adjacent sites maintain the molecular planes parallel in the dye super-helix, but the degree of ordering is probably not large since the observed circular dichroism of the DNA-AO complex (Fig. 2) is an order of magnitude smaller than that[7] of the helical polymer formed by pseudo-isocyanine.

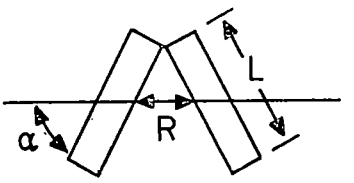
BIOCHEMISTRY



Geometrical Rearrangement of Aggregated Chlorophyll *in vivo* during the Greening Process

It has been previously reported[1] that the emission maximum from aggregated chlorophyll, in *Euglena gracilis* strain *Z*, shifts toward longer wave-lengths as the concentration of chlorophyll increases in the cell. In an earlier paper[2] it was assumed that the shift toward longer wave-lengths arises from the formation of a distribution of molecular aggregates of different sizes. In this treatment, the geometry of the aggregates was presumed to undergo no change during the greening process. A calculation of the aggregate sizes and their absorption maxima corresponding to the experimentally observed emission bands was made.

Alternatively, the observed shift could arise from a single-sized aggregate which undergoes a change in the angle and distance between the molecules forming the aggregate. An expression given by McRae and Kasha[3]:

$$\Delta\tilde{\nu}_A = \frac{4m^2}{hcR^3}\left(\frac{N-1}{N}\right)(1+\cos^2\alpha) \qquad (1)$$

describes quantitatively the absorption properties of dye aggregates, where $\Delta\tilde{\nu}_A$ is the separation, in wave numbers, between the two aggregate absorption bands, m is the transition moment of the monomer, N is the number of monomer units forming the aggregate, R is the distance between charge centres, and α is the angle between the plane of the molecules and the axis of the aggregate. These parameters are indicated in the schematic representation of the structure of the chlorophyll dimer, shown here.

As seen from the geometry, $L \cos\alpha = R$. We can eliminate the cos α term from equation (1) to give:

$$\Delta\tilde{\nu}_A = \frac{4m^2}{hcL^2}\left(\frac{L^2+R^2}{R^3}\right)\left(\frac{N-1}{N}\right) \qquad (2)$$

This equation can be rewritten in terms of emission as described previously[2], where $\tilde{\nu}_F' - \tilde{\nu}_F''$ is the separation, in wave numbers, between the monomer and aggregate emission maxima.

$$\tilde{\nu}_F' - \tilde{\nu}_F'' = \frac{2m^2}{hcL^2}\left(\frac{L^2+R^2}{R^3}\right)\left(\frac{N-1}{N}\right) = \delta \qquad (3)$$

Rearranging terms yields the cubic equation:

$$\delta R^3 - BR^2 - BL^2 = 0 \qquad (4)$$

where $B = \frac{2m^2}{hcL^2}\left(\frac{N-1}{N}\right)$.

It is assumed that the observed shift in emission maximum arises from a change in the distance between charge centres, R, in an aggregate of size, N, and that the centre of charge for chlorophyll is concentrated in the centre of the molecule. A calculation of the aggregate emission maximum, $\tilde{\nu}_F''$, in wave numbers, as a function R, can be made from equation (4). In these calculations the wave number for the monomer emission maximum, $\tilde{\nu}_F'$, is taken as 14,556 cm^{-1} (687 mμ) (ref. 2). The value of B is calculated to be $0{\cdot}714 \times 10^{-5}$ E.S.U./erg cm^3 when the aggregate is a dimer (that is, $N = 2$) and $m^2 = 3{\cdot}26 \times 10^{-35}$ E.S.U. (ref. 4) and $L = 15$ Å (this corrected value supersedes that given in ref. 5). From the relationship $R = L \cos\alpha$, the angle α is also calculated. These values and the analogous ones for larger-sized aggregates (that is, $N = 3, 4, 6$ and ∞) are given in Table 1. The results are also plotted in Fig. 1.

Table 1. Geometrical Values for an Aggregate Calculated from Emission Data

N	Long wave-length emission maximum (observed) mμ	δ cm^{-1} (observed)	R (Å)	α

The first aggregated form observed in *Euglena* (light, 7 h) has an emission maximum at 717 mμ (ref. 1). If only dimers are present, then $R = 6{\cdot}8$ Å and $\alpha = 63°$. After *Euglena* has been in the light for 80 h, the emission maximum is shifted to 734 mμ. If this form is exclusively

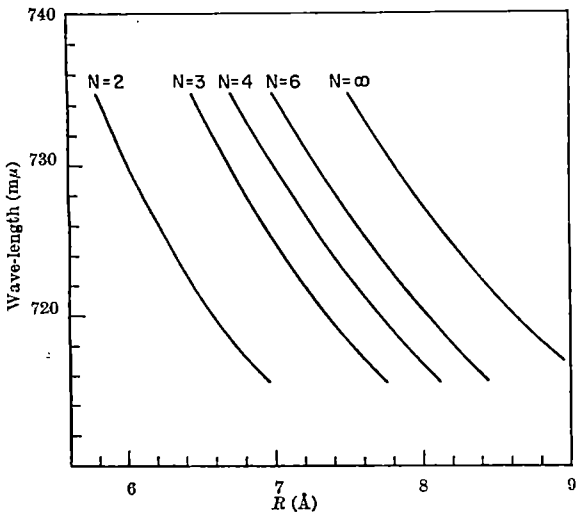

Fig. 1. Relationship between the long wave-length emission maximum from *Euglena* and the distance between charge centres, R, of the molecules forming the aggregate. The relationship is shown for aggregates of different sizes; N being the number of monomer units forming the aggregate. Emission is measured at 77° K and sensitized with blue light (436 mμ)

dimeric, R is 5·8 Å and α is 67°. If the aggregate size *in vivo* is larger than dimeric, then, for a given emission maximum, the value of R is increased considerably with increasing N (Fig. 1) and α decreases.

Up to this point it has not been possible to determine if the observed spectral shift of fluorescence *in vivo* arises from an increase in aggregate size or from a change in the geometry of the dimer, or a combination of these factors. Resolution of the *in vivo* absorption spectra into monomeric and aggregate components should enable one to decide between these possibilities, as shown here.

A relationship between α and the extinctions of the two aggregate absorption bands can be obtained[4] from the work of McRae and Kasha[3]:

$$\frac{\varepsilon''_s}{\varepsilon''_L} = \tan\alpha \qquad (5)$$

where $\frac{\varepsilon''_s}{\varepsilon''_L}$ is the ratio of the extinctions of the short and long wave-length absorptions of the aggregate. If, in the aggregate absorption spectrum, this ratio remains constant during greening (while the emission maximum shifts to longer wave-lengths), then α, and hence R, also do not change. Then the shift in emission maximum to longer wave-lengths can be ascribed solely to an increase in aggregate size. In that event the aggregate size, N, can be determined uniquely from the absorption or emission data. Substituting equation (5) in equation (1) we obtain:

$$\delta = 2\left(\frac{N-1}{N}\right)\frac{m^2}{hcL^3}\left[2+\left(\frac{\varepsilon''_s}{\varepsilon''_L}\right)\right]\sqrt{1+\left(\frac{\varepsilon''_s}{\varepsilon''_L}\right)^2} \qquad (6)$$

when $\frac{\varepsilon''_s}{\varepsilon''_L}$ is constant the wave number separation between the aggregate absorption bands *in vivo* should also vary during the greening process according to equation (1) reflecting increased aggregation. If $\frac{\varepsilon''_s}{\varepsilon''_L}$ varies the shift in long-wave-length emission may be resolved into contributions due to a change in geometrical arrangement of the aggregate and to an increase in size of the aggregate. For the case where the experimentally determined value of δ varies linearly with $\left[2+\left(\frac{\varepsilon''_s}{\varepsilon''_L}\right)^2\right]\cdot\left[1+\left(\frac{\varepsilon''_s}{\varepsilon''_L}\right)^2\right]^{\frac{1}{2}}$, then the shift in long wave-length emission is due solely to geometrical rearrangements. Furthermore, for this case N may be determined uniquely with the aid of equation (6). For the case where δ is not a simple function of the ratio $\frac{\varepsilon''_s}{\varepsilon''_L}$, then both the aggregate size and geometry are changing; with the aid of equation (6) a value of N can be estimated.

Synthesis and Metabolism of Halothane-1-^{14}C

Evidence that the volatile anæsthetics are not biologically inert has been developed recently in reports from this laboratory. We have measured the extent of production of carbon dioxide from ^{14}C-diethyl ether, ^{14}C-chloroform and ^{14}C-methoxyflurane ($^{14}CH_3OCF_2CCl_2H$)[1]. Carbon-14-labelled halothane ($CF_3CBrClH$) has not been available to us until recently when it was prepared by one of us (E. R. L.).

Halothane-1-^{14}C was synthesized starting with chloroacetic-1-^{14}C acid obtained from New England Nuclear Corporation. The amount used was 93 mg with a total isotopic activity of 1 mc. This was mixed with 30 g of cold chloroacetic acid. This mixture plus 170 g sulphur tetrafluoride and 50 μl. water were placed in a 300 ml. stainless steel pressure vessel and heated with shaking to 198° C (2,100 psig). These conditions were maintained for 63 h. In this manner, 25 g of trifluoroethyl chloride-1-^{14}C was prepared and afterwards brominated by means of a vapour phase thermal bromination in the apparatus shown in Fig. 1.

Trifluoroethyl chloride-1-^{14}C (25 g) was dissolved in liquid bromine (33 g) at 0° C and placed in the jacketed dropping funnel. The temperature of the solution was maintained at about 0° C by circulating ice water. The solution was added dropwise over a period of 30 min and heated to 540° C. The effluent from the reaction was condensed in the dry-ice-acetone trap.

The condensate in the trap was allowed to warm to about 0° C and the condensed hydrogen bromide flashed off. The excess bromine was destroyed by adding aqueous sodium bisulphate to the trap. The water-insoluble layer was transferred directly to the post of a small distillation column. The distillation yielded 8·5 gm of unreacted trifluoroethyl chloride-1-^{14}C and 8·4 g of crude halothane-1-^{14}C. The unreacted trifluoroethyl chloride-1-^{14}C was dissolved in 12 g of bromine and recycled through the reactor, yielding an additional 4·6 g of halothane-1-^{14}C.

The crude halothane-1-^{14}C (13 g) was purified by gas-liquid chromatography using a 5/8 in. × 10 ft. *bis*-(2-ethylhexyl) sebacate on 'Chromosorb' column with a temperature of 100° C. After three passes through the column, 6·25 g of halothane-1-^{14}C was obtained having a purity greater than 99·9 per cent. This material did not contain any 1,1,1-4,4,4-hexafluoro-2,3-dichlorobutene-2.

The halothane-1-^{14}C was then used to examine the possibility that this material is converted to carbon dioxide. This was carried out as described previously[1]. The labelled material was injected intraperitoneally in 0·1-ml. quantities which contained $5{\cdot}57 \times 10^6$ DPM. Following the injection, the animal was placed in a metabolism cage which allowed the complete recovery of expired gases including the carbon dioxide. The urine was also collected.

The extent of conversion of the number one carbon of halothane to carbon dioxide is very limited since only

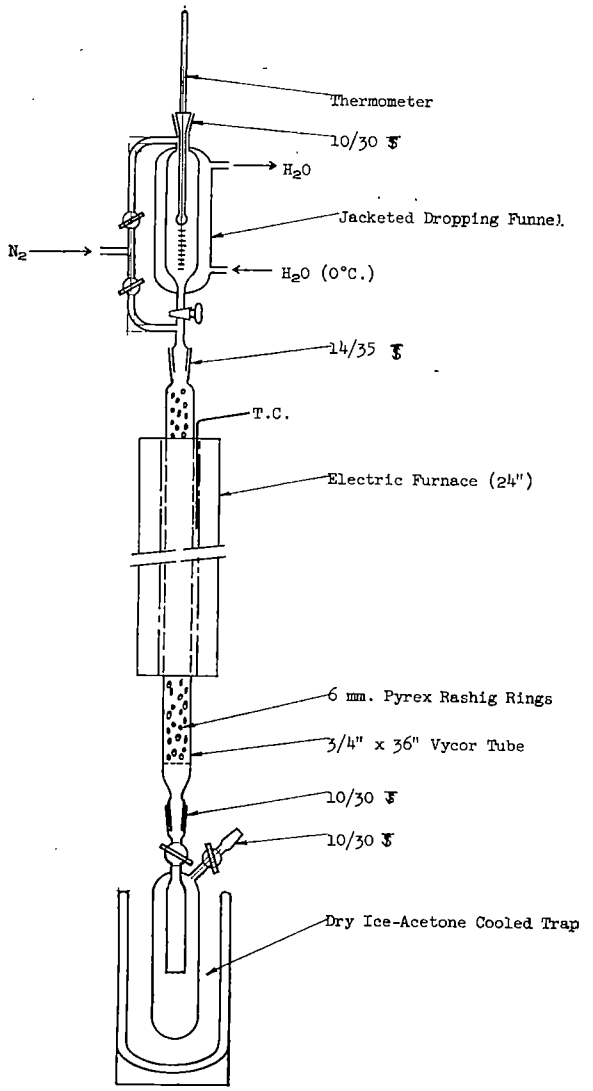

Fig. 1. Apparatus for bromination of trifluoroethyl chloride-^{14}C

0·84 per cent (0·41–1·23 per cent from nine animals) of the injected dose appeared as carbon dioxide in 24 h. This amount of conversion may be due to one of two causes. (1) This may represent the extent of defluorination of the number one carbon and thus the complete breakdown of the molecule. (2) This may represent an easily metabolized impurity, although the purity data do not indicate this.

The extent of labelled metabolites appearing in the urine was also determined. In a 24-h period, an average of 1·56 per cent (0·95–2·68 per cent from nine animals) of the injected dose was found in the urine as non-volatile, unidentified products. Presumably, however, they are dechlorinated and/or debrominated halothane residues conjugated or in some other manner made non-volatile. We have shown that dechlorination does occur[1,2].

The total recovery of all isotopic activity in a 24-h period was 95–103 per cent.

Differential Action of Neuraminidase on Human Serum Alkaline Phosphatases

Boyer[1] noted that blood serum from normal adults produced in starch-gel zymograms one or two major zones of phosphatase activity between the transferrin and the haptoglobin 1–1 regions. Occasionally there was also a faint band near the origin. Similar patterns were later reported by other investigators[2–5].

Arfors *et al.*[5] described a phosphatase polymorphism based on the number of bands in the major zones. Type-1 phosphatase is characterized by a single band in the leading zone, and type-2 phosphatase by one or two additional bands in the slower major zone. A relationship was found between the phosphatase type and the Lewis blood group. Among individuals with type O red blood cells, serum samples of all 16 who were Le (a+ b-) contained type-1 phosphatase, and the sera of 30 of 41 individuals who were Le (a-b+) contained type-2 phosphatase. The authors suggested that one of the components in the slower zone may be complexed with a blood group substance (Le^b or H), since its enzymatic activity was decreased after incubation with anti-Le^b serum. A correlation between serum phosphatase type and red blood cell group has also been demonstrated recently in cattle[6] and in sheep[7].

This report concerns a fundamental difference in the structure of the human serum alkaline phosphatase isozymes. Incubation of serum with neuraminidase, prior to electrophoresis, decreased the anodal migration of three of the four isozymes observed in starch-gel zymograms. The results indicate that terminal neuraminic acid occurs in three of the isozymes, but is absent from one of them. The neuraminidase-resistant enzyme was inhibited by L-phenylalanine, an organ-specific inhibitor for intestinal alkaline phosphatase[8].

Serial dilutions of *Vibrio cholerae* neuraminidase (Behringwerke AG., Marburg, Germany) were prepared in 0·05 M sodium acetate, 0·06 M NaCl, 0·004 M $CaCl_2$, *p*H 5·6. The greatest dilution which, when added to an equal volume of serum, decreased the electrophoretic migration of type-1 phosphatase was considered, arbitrarily, to contain 1 unit per 0·05 ml. To each 0·05 ml. portion of serum was added an equal volume of neuraminidase; the mixtures were incubated for 20 h at 37° C and horizontal starch-gel electrophoresis[9,10] of the incubation mixtures was performed. The methods of Boyer[1] and of Arfors *et al.*[5] were used in the preparation of the zymograms. We find that the two procedures give comparable results. The method of Boyer produces less background staining, but it is not so sensitive as the method of Arfors *et al.*

Fig. 1, a photograph of the zymograms, shows that incubation with neuraminidase decreased the rate of anodal migration of type-1 phosphatase and of the similar fast component of type 2. The slow component of type 2 was unaffected, even when the concentration of neuraminidase was 10,000 times that required to produce detectable changes in the fast component. The activity of the neuraminidase-resistant component was almost completely abolished by staining in substrate mixture[5] containing 0·01 M L-phenylalanine (Fig. 2).

We examined five type-2 sera which showed two bands in the slow major zone. In all cases, only the faster of the two components was neuraminidase-resistant. After incubation with neuraminidase, the sensitive component could not be located on the gel. Possible explanations are that it did not enter the anodal side of the gel, that it migrated to the same position as the neuraminidase-treated fast component, or that the removal of neuraminic acid inactivated the enzyme. The migration of the faint band near the origin was also decreased by the action of neuraminidase. This band, not discernible in Fig. 1, was detected in each of 30 sera when the staining process was continued for 24 h.

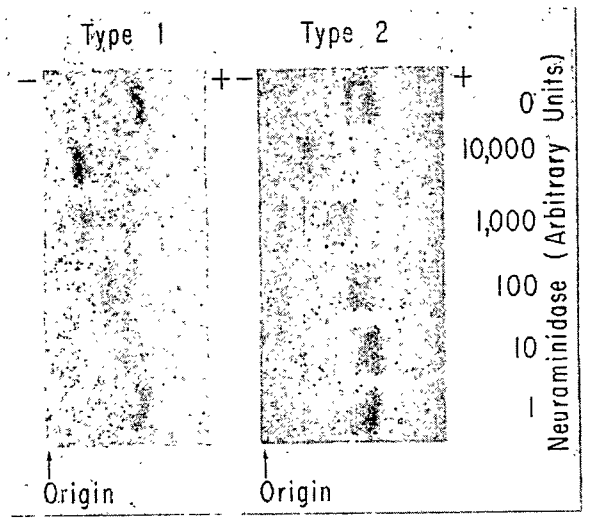

Fig. 1. Starch-gel zymograms of serum alkaline phosphatases, showing the effect of neuraminidase. Six portions of serum, each treated with the indicated quantity of neuraminidase, were inserted in each gel. After electrophoresis the gels were stained according to the method of Boyer[1]. The ends of each of the stained bands have been marked on the photograph, using the original gel as a guide

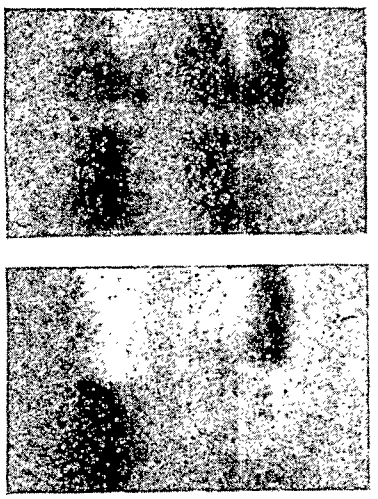

Fig. 2. Starch-gel zymograms, showing specific inhibition by L-phenylalanine of the slow component of type-2 phosphatase. The preparation of the two gels differed only in the inclusion of L-phenylalanine in the substrate mixture for the lower one. The upper insertion in each gel was serum plus buffer; the lower, serum plus neuraminidase. The origin was at the extreme left; the anode was to the right

The decreased anodal migration is caused by the removal of neuraminic acid (or a derivative thereof), which has a free carboxyl group. This technique has been used to demonstrate the occurrence of neuraminic acid in several plasma proteins. It has been particularly useful because the loss of neuraminic acid did not interfere with the specific tests used to detect the proteins. For example, incubation with neuraminidase does not abolish the binding of iron by transferrin, the interaction of haptoglobin with hæmoglobin to form a peroxidase complex, or the binding of thyroxin by thyroxin-binding globulin[11]. Also, we have observed decreased mobility, but unaltered enzymatic activity, of ceruloplasmin and pseudocholinesterase after incubation of serum with neuraminidase. In the case of pseudocholinesterase, Svensmark and Kristensen[12] have clearly shown that the decrease in mobility is due to a change in the isoelectric point of the enzyme from 2·9–3·0 to 6·7–7·0 as a result of treatment with neuraminidase.

Immunological evidence[13,14] indicates that there are at least three antigenic classes of human non-specific alkaline phosphatases. The apparently closely related enzymes of liver, bone, spleen and a major kidney component form one class; intestinal phosphatase and placental phosphatase, which are partially cross-reactive with each other and with a major kidney component, represent the other two classes[13]. The zymograms of Hodson and associates are labelled to show the liver enzyme in the fast major zone, and intestinal and bone phosphatase in the slow major zone. The inhibition investigations of Fishman and Kreisher[4], using L-phenylalanine, support the view that the intestinal enzyme is localized in the second zone. Our results demonstrate that it is this phenylalanine-sensitive enzyme which is resistant to the action of neuraminidase. A minor component near the origin can be seen in zymograms of various tissue extracts prepared by Boyer[13]. The tissue-of-origin of the similar serum component, therefore, cannot be specified at present.

Heretofore, the genetically determined protein variants have been found to differ either by amino-acid substitutions in polypeptide chains[15] or by the association of fundamental units in various combinations, as, for example, in the lactate dehydrogenases[16]. The present work suggests an additional way in which isozymes may differ, namely, in their carbohydrate components. It is possible that in detailed structural analysis of the glycoproteins all three modes will be encountered simultaneously.

A Specific Elastolysate Test

Since the discovery of the splitting effect of pancreatic elastase on elastin[1,2], many authors have described methods for estimating elastolytic activity. In this laboratory we have attempted to develop a salt turbidity test as a more convenient method, by using an alkaline salt, Na_2CO_3, or a neutral salt, NaCl, or an acidic one, $(NH_4)_2SO_4$.

Elastolysates produced by acting of elastase on elastin[2–5] become turbid when treated with saturated solutions of Na_2CO_3, NaCl or $(NH_4)_2SO_4$, and the maximal turbidity values in elastolysates with each of these first two saturated salt solutions are in a ratio of 1 : 2, and 1 : 1 with that of $(NH_4)_2SO_4$ (v/v).

The intensities of the turbidities in these reactions depend first on the kind of saturated salt solution and indicate the following sequence: NaCl < Na_2CO_3 < $(NH_4)_2SO_4$. Under these conditions, saturated solutions of Na_2CO_3 or NaCl do not give any turbidity reaction with some other native proteins or proteins digested by elastase, while $(NH_4)_2SO_4$ has a general protein-precipitating effect.

Each of these saturated salt solutions yields a different value for the same elastolysate specimen at a given time,

and finally determines its different curve of behaviour (Table 1).

Table 1

Time of the elastolysate (min)	5	10	15	20	25	30	60	120	240
Turbidities (colorimetric divisions)									
with sat. Na_2CO_3 :	14	41	59	66	72	79	95	97	88
with sat. NaCl :	0	15	23	36	44	47	—	88	78
with sat. $(NH_4)_2SO_4$:	22	97	128	142	148	149	—	170	180

All these turbidities and precipitates are of different stabilities and thus most of the turbidity values (photocolorimetric divisions), especially in the experiments with Na_2CO_3, are not completely in accordance with those of the corresponding precipitates estimated by kjeldahlometry or gravimetry. Nevertheless, the comparison of these results with those of other general methods shows that this Na_2CO_3 turbidity test is useful for following the activity of elastase on elastin, and it is concluded that these turbidity reactions can be taken as specific reactions for elastin and elastolysates. They have some other advantages over other methods in that (*a*) the reagent is easy to prepare and is stable and consistent, and (*b*) the reactions take only 10 min. The results can be graded objectively, but only semi-quantitatively.

Interactions of Peroxidases and Catalases between *Phaseolus vulgaris* and *Pseudomonas phaseolicola* (Halo Blight of Bean)

The increased activity of oxidative enzymes in plants caused by fungi, viruses or other organisms has been known for many decades[1]. It has also been suggested that the resistance of plants to micro-organisms was due to compounds, probably phenolics, which were formed after the invasion of the pathogen[2]. Since then in many cases correlations between higher activities of phenol oxidases or peroxidases and resistance have been reported[3]. In the case of halo blight of beans, it was suggested that peroxidases play a part in resistance[4]. In fungus-infected beans the appearance of a 'phytoalexin' which induced resistance has been reported[5], but recent investigations showed that it was difficult to explain all resistant reactions in bean plants with only the phytoalexin concept[6]. It is not known if a specific compound induces resistance against the halo blight organism or if a general enhancement of oxidative processes (hypersensitive reaction) is the primary cause of resistance.

Our investigations showed that increased activities of peroxidases caused by the infection could be detected earlier in the resistant variety and that the activity remained higher during the first few days after infection as compared with the susceptible variety. This would suggest that in the case of the susceptible combination the bacteria did not trigger, or were able to delay, this defence mechanism of the bean plant. Attempts to study interactions of host and parasite were often complicated by the need to differentiate between the contributions of the two organisms. Therefore we hoped to obtain a better understanding of the biochemistry of this disease by analysing the proteins of healthy and infected bean leaves and of the bacteria. The first experiments showed clearly that the infection does change the protein composition of the bean leaf and that this change is different in susceptible and resistant varieties[7]. By application of a new technique, polyacrylamide disk electrophoresis, better characterization of the protein changes was attained.

The conditions for growing the bean plants, for infecting the leaves, and for extracting the proteins were the same as described earlier[7]. The disk-electrophoresis method of Ornstein and Davis[8] was used with some minor technical modifications[9]. Bands of enzymatic activity were located on the gels by standard histochemical methods[10].

Staining with amido-black did not reveal marked differences between protein bands of healthy and infected leaves. However, zymograms for several enzymes showed changes due to infection. The details will be published later. In general, increased activities of the host enzymes were observed for oxidases and dehydrogenases, whereas some hydrolytic enzymes (phosphatases, esterases) of the host showed lower activity after infection. In most cases, when new zones were seen in infected leaves, they appeared to be of bacterial origin (for example, acid phosphatase, esterase, malate dehydrogenase, catalase).

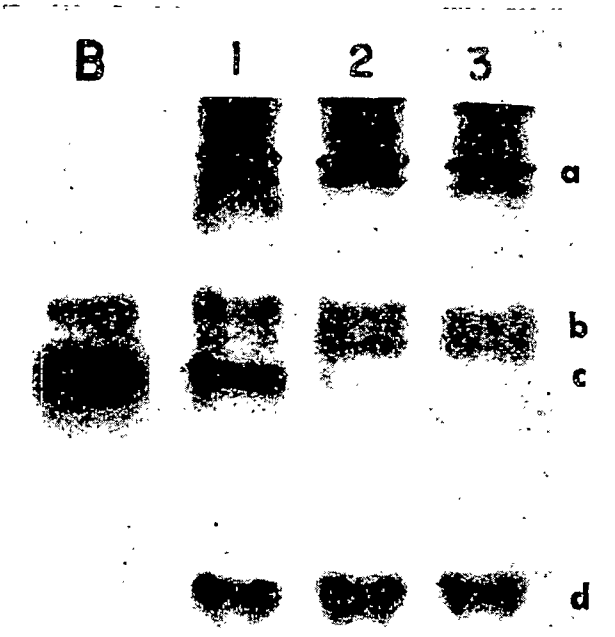

Fig. 1. Peroxidases and catalases in bean leaf and bacterial extracts after disk-electrophoresis. Bands *a-d* were developed with 2×10^{-2} M catechol and 0·3 per cent hydrogen peroxide.
B, bacterial extract; 1, infection centre; 2, surrounding yellow halo; 3, surrounding green tissue

One of the most striking changes was the appearance of bacterial catalase in the infected leaves, as shown in Fig. 1 (band *c*), when catechol (2×10^{-2} M) and hydrogen peroxide (0·3 per cent) were used for development. It was established that band *c* was a catalase because it showed a positive reaction with the starch–iodide method[11], and it did not possess detectable peroxidatic activity with guaiacol as a substrate. Two commercial catalase preparations showed the same characteristics and also oxidized catechol. In contrast the main plant, band *b*, had peroxidatic activity with guaiacol as well as catalytic activity and all upper bands (*a*) showed only peroxidatic activity. Band *d* is probably a phenol oxidase. As shown in Fig. 1, sonic extracts of bacteria grown on peptone–dextrose–beef-extract agar showed a strong band at the same position with the same biochemical characteristics as those described for band *c*. Other evidence for the

bacterial origin of band *c* may be derived from the fact that extracts from the 'greasy' infection centres contained a large amount of this catalase whereas only low activity was found in the surrounding yellow halos and no activity could be detected in the surrounding green tissue (see Fig. 1, 1–3). In contrast, systematically chlorotic leaves contained only low amounts of band *c*, which is in accordance with the report that these leaves contain only a few bacteria[12]. A faint positive reaction was obtained from infected resistant leaves, but this faint zone tended to fade in later infection stages. It has been reported repeatedly[13,14] that in resistant leaves low populations of inoculated bacteria are able to survive for some time. In susceptible leaves band *c* was detectable as early as one day after infection and became very strong during the latter stages of infection. Whether the enzyme is actively excreted by the bacteria or appeared only because of bacterial autolysis is not known. However, its high activity in infected tissues suggested that this enzyme influenced the host metabolism.

One explanation for the influence of catalase on the host metabolism would be an inhibition of host peroxidases by competition for hydrogen peroxide. *In vitro* tests with guaiacol showed that bean peroxidases are markedly inhibited by bacterial extracts. This inhibition could be reduced by adding higher concentrations of hydrogen peroxide and no inhibition occurred with boiled bacterial extracts. Curves for the inhibition of bean peroxidase by commercial catalase and for the reversal of the inhibition by hydrogen peroxide were very similar to those for bean peroxidase and bacterial extracts. When guaiacol was oxidized by a plant extract and hydrogen peroxide the dark brown coloured solution could be decolorized by addition of catalases as well as bacterial extracts.

The peroxidatic activity of catalase is often considered physiologically more important than catalytic activity[15]. We also found *in vitro*, under relatively high concentrations of hydrogen peroxide, catechol was oxidized by the bacterial catalase but guaiacol was not. This indicates that peroxidases oxidize compounds which are not affected by catalases under our conditions. Similar differences were reported for the coupled oxidation of phenolic hydrogen donors by peroxidases and catalases[16]. We do not know which peroxidatic pathways are involved in the hypersensitive reactions in the bean leaf and if these reactions could also be mediated by catalases.

In order to examine the effect of catalases *in vivo* we fed bean shoots with commercial catalase. This treatment did not enhance oxidation but markedly inhibited ageing reactions which normally progress rapidly in cuttings. That is, the yellowing as well as the increase in peroxidase activity were delayed by treatment with catalase. In addition an electrophoretically detectable peroxidase band, which normally increased during ageing, was very low. The same effect can be seen in Fig. 1 where the main plant peroxidase band *b* shows a lower activity in extracts from the infection centres, as compared with the surrounding tissue (compare Nos. 1–3).

We also compared two equally fast-growing bacteria. *PP* 8 (ref. 17) was very virulent and showed high catalase activity. *B*-845 (ref. 18) showed low virulence (based on symptom expression) and low catalase activity. During the first days after infection, the increase in peroxidase was higher in the bean leaves infected with *B*-845 compared with *PP* 8 infected leaves. However, another very slow growing strain[19] showed very little catalase activity but was nevertheless virulent and the increase in host peroxidase was relatively low. Another mechanism of virulence seems to be operating in this case. This might be the degree of toxin production, the chemical nature of which as well as its mode of action are still unknown. It has been suggested recently for *Pseudomonas tabaci* that the toxin production is high in slow-growing strains, and negative correlations with catalase activity were reported[20]. This would be in accordance with our own observation that a non-toxin producing but virulent strain of *Pseudomonas phaseolicola*[17] showed a very high catalase activity.

Catalases are very common among bacteria and fungi; however, not much is known about their biochemical or plant pathological importance. The latter may be partially due to the fact that until recently it was difficult to estimate to any degree the participation of host and parasite in biochemical reactions of the host–parasite relationship. The demonstration of a strong bacterial catalase in infected plants and other observations led us to the suggestion that with certain combinations bacterial catalases may be one factor for virulence by depressing the activity of peroxidases involved in the defence reactions of the host.

Presence of Several Phenolic Components in Fruit Proanthocyanidins

Forsyth and Roberts[1] reported that chromatographically homogeneous cacao proanthocyanidin dimer yielded epicathechin and a new leucocyanidin when heated with 0·1 N hydrochloric acid, and cyanidin when heated with stronger acid. Similar dimeric proanthocyanidins were isolated from *Crataegus oxyacantha* and *Gleditschia triacanthos* by Freudenberg and Weinges[2–5]. The astringent proanthocyanidins isolated from various fruit tissues, unlike the above dimers, were found to be highly polymerized and not chromatographically mobile. This was true of the originally isolated persimmon proanthocyanidin[6,7] and of the more recently isolated persimmon[8] and apple[9] preparations. These purified preparations, which were not mobile on paper in any of the solvent systems tested, were, however, found to yield mobile phenolics without any accompanying anthocyanidins when heated with dilute hydrochloric acid. Under these conditions several chromatographically identified phenolics and a non-mobile but apparently less highly polymerized fraction were obtained. The original preparation, and the residue after dilute acid hydrolysis, which was insoluble in ethyl acetate, were found to yield identifiable anthocyanidins on heating with more concentrated hydrochloric acid. The results of these observations, which continued investigations previously reported on the mechanism of acid conversion of proanthocyanidins into their corresponding anthocyanidins[10], are reported here.

Portions of 50–80 mg of purified apple, carob, grape and persimmon proanthocyanidins were dissolved in 25 ml. of 0·1 N hydrochloric acid and heated in boiling water for 20 min. The apple preparation was obtained from 'Gravenstein' apple flesh as the *n*-butanol-soluble, hexane-precipitated fraction[9]. The persimmon preparations were compared; one was the methanol-soluble, acetic acid-insoluble preparation from Japanese astringent persimmons ('Yokono' variety), dissolved in ethanol and precipitated with ether[6,7], the second was obtained from California-grown astringent persimmons ('Niu Nai') by methanol extraction, precipitation with lead acetate, deleading, solution in ethanol and precipitation with hexane[8]. Both of the persimmon preparations gave similar results. The grape preparation was from 'Colombard' grape pomace, as butanol-soluble and ether-precipitable fractions[10]. The carob preparation was obtained from a methanol extract of green carob pods after lead precipitation and deleading, as the butanol-soluble hexane precipitable fractions. In all cases solution in butanol or in ethanol and precipitation with ether or hexane were repeated to purify the preparation further.

The dilute acid hydrolysate, free of visible anthocyanidin, was extracted with 40 ml. of ethyl acetate. The ethyl acetate extract after dehydration with sodium sulphate was concentrated in a rotary vacuum evaporator at below 40° C to 2 ml. The concentrate so obtained gave a strong vanillin-positive reaction and formed a pigment with diazotized *p*-nitroaniline which was characteristic of flavonols. Two-dimensional ascending solvent front chromatograms were prepared from the ethyl acetate extract using *n*-butanol–acetic acid–water (6 : 1 : 2) as the first solvent and 6 per cent acetic acid as the second solvent[11]. Two chromatograms were prepared, one developed by spraying with diazotized *p*-nitroaniline and the other with vanillin-hydrochloric acid. The mobile phenolics that were found were identified by colour with the above reagents, by fluorescence in ultra-violet light, by reported R_F values in the literature, and checked by comparison with authentic phenolics which were chromatographed under similar conditions or co-chromatographed.

The apple-flesh preparation yielded *d*-catechin and *l*-epicatechin. Both the persimmon preparations yielded gallic acid, *l*-gallocatechin and *l*-gallocatechin gallate. The grape preparation yielded *d*-catechin, *l*-epicatechin, *l*-epicatechin gallate, protocatechuic acid, phloroglucinol, kæmpferol, quercetin and an unknown phenolic. The carob pod preparation yielded gallic acid, *d*-catechin, *l*-epicatechin, *l*-gallocatechin, *l*-epicatechin gallate, phloroglucinol, ferulic acid, quercetin and myricetin.

It is interesting that, except in the case of the persimmon, *d*-catechin and *l*-epicatechin occurred in the dilute acid hydrolysate of the astringent proanthocyanidin. In the proanthocyanidins, which were predominantly leucodelphinidin, persimmon and carob, gallic acid was found. The occurrence of quercetin and phloroglucinol in both the grape and carob preparations was also of interest. The occurrence of quercetin in the grape was paralleled by myricetin in the carob as corresponding flavonols.

On strong acid hydrolysis[9] the apple-flesh preparation yielded two anthocyanidins, predominantly cyanidin and much smaller concentrations of pelargonidin. Both the persimmon preparations yielded largely delphinidin with smaller amounts of cyanidin. Ito and Oshima[6] had previously reported the presence of leucodelphinidin-3-glucoside in persimmon proanthocyanidin. The grape preparation yielded only cyanidin and the carob preparation yielded mainly delphinidin with smaller concentrations of cyanidin. This preparation, however, was made from the methanol extract of whole green carob pods including the seeds. Goldstein, however, had observed (unpublished) that the carob pod tissue free of seeds yielded only delphinidin while the carob seed testa yielded only cyanidin.

The occurrence of a number of chromatographically identifiable phenolics in the products of dilute acid hydrolysis, varying from two for the apple tissue preparation to eight or more for the carob and grape tissue preparation, and the presence of more than one anthocyanidin in the products of concentrated acid hydrolysis indicate either that the proanthocyanidins are quite complex or that the preparations contained mixtures of leucocyanidins, leucodelphinidins and various phenolic compounds. Additional purification by continuous liquid–liquid extraction and fractional elution is being carried out in an attempt to obtain more highly purified preparations for chemical identification.

We thank Dr. T. Nakabayashi of the University of Shizuoka, and Dr. A. Holmes of the Indian Tea Association, for samples of authentic polyphenols.

Sub-cellular Localization of Rat Kidney Alkaline Phosphatase

In mammalian cell cultures alkaline phosphatase is regulated by both inductive and repressive mechanisms[1]. In preparation for further investigations of the mechanisms of alkaline phosphatase control, the sub-cellular localization of this enzyme was re-investigated, using newer techniques[2,3]. Previous investigations, using the kidney and intestine of several different mammalian species, have shown that the highest alkaline phosphatase activity resides on the microsomes[4–6].

Three separate fractionations and analyses were performed using different rats. A representative experiment is described.

An adult rat was killed by decapitation. The kidneys were removed and the capsules stripped. The combined weight of both kidneys was 3 g. Further manipulations were carried out at 4° C. The kidneys were minced, washed thoroughly on a nylon filter with 0·25 M sucrose and homogenized in 27 ml. of 0·25 M sucrose with a motor-driven 'Teflon' homogenizer (*TRI-R* Instruments No. *S*-23 pestle and *S*-37 tube). Ten-ml. portions of homogenate were carefully layered over equal volumes of 0·34 M sucrose and fractionation proceeded as outlined in Fig. 1. Nuclei were isolated by the method of Hoogeboom[2], except that calcium chloride was omitted from the solution since calcium ions in the suggested concentration (0·18 mM)[3] inhibit alkaline phosphatase activity. Following centrifugation at 600 r.p.m. (International refrigerated centrifuge, yoke No. 253) for 20 min, the top layer was separated from the bottom layer which contained the sedimented nuclei. The top layer was fractionated into a mitochondria–lysosome fraction and a microsome fraction by the method of Ernster *et al.*[3]. The fraction that sedimented at 12,500 r.p.m. in Spinco rotor No. 40 (Beckman model *L* ultracentrifuge) was called the mitochondria–lysosome fraction. We focused our further purification efforts on the supernatant containing the microsomal sub-structures. These were sedimented at

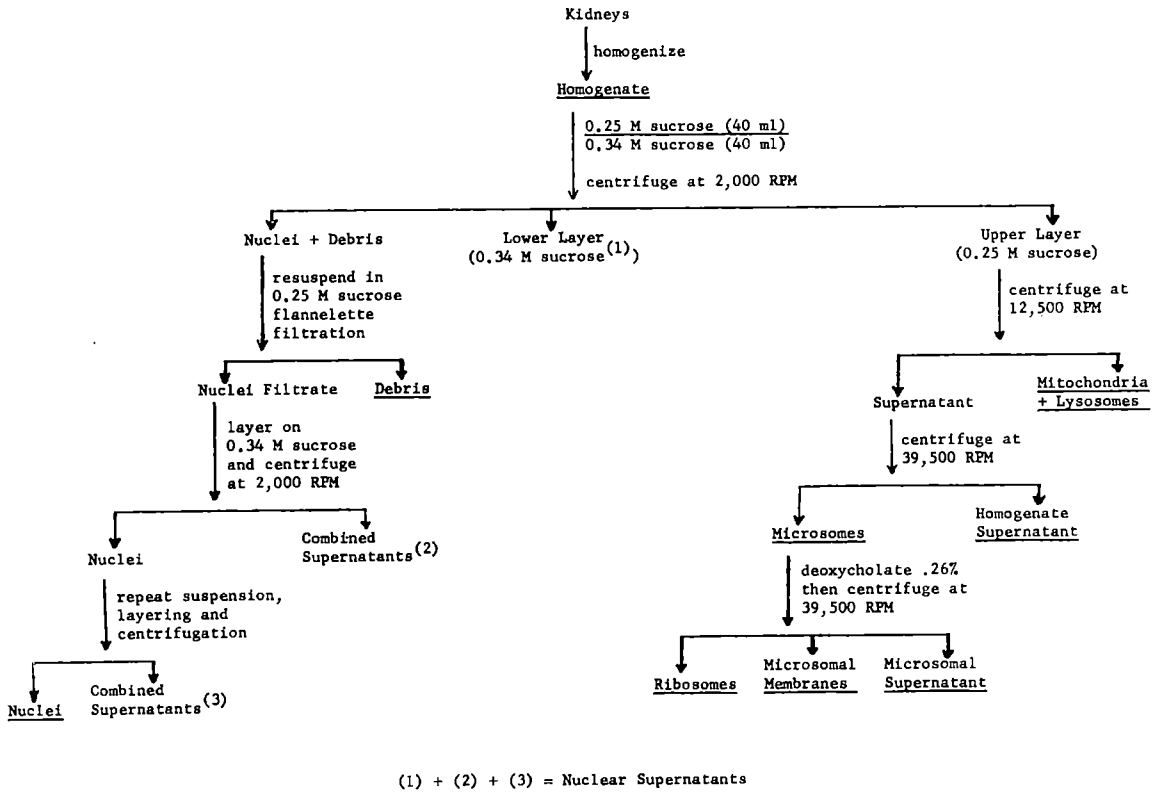

Fig. 1. Fractionation of rat kidney sub-cellular particles. The underlined fractions were assayed

39,000 r.p.m. in Spinco rotor No. 40 for 2 h. The pellet, containing microsomes, was re-suspended in 0·25 M sucrose and re-sedimented as indicated here. This now washed microsomal pellet was re-suspended in 0·25 M sucrose. Three-quarters of the microsome fraction was taken and further fractionated into ribonucleoprotein particles (ribosomes)[7], microsomal membranes and a microsomal supernatant by treatment with 0·26 per cent deoxycholate at *p*H 7·4 as shown in Fig. 1 (ref. 3). Ernster *et al.* have demonstrated that the tightly packed bottom layer of the two-layered precipitate is predominantly ribosomes, whereas the loosely aggregated upper layer of the precipitate consists of partially disrupted microsomal membranes. These two layers were easily separated by washing the membranes away from the ribosomes. The latter pellet could only be re-suspended by homogenization.

The nuclear sediment in the bottom layer of the initial centrifugation supernatant was re-suspended in 20 ml. of 0·25 M sucrose. This fraction was filtered through a cloth flannelette and re-sedimented twice from 0·25 M sucrose through 0·34 M sucrose[8]. Nuclei prepared by this procedure appeared reasonably free of other visible cell particles using Wright stain and light microscopy[8].

The activities of enzymes which are concentrated in certain cell particles have been used as criteria for cellular fraction homogeneity[8]. The β-glucuronidase and acid phosphatase were assayed as enzymes localized in lysosomes. Acid phosphatase can be found in certain nuclear fractions, but the significance of this finding is uncertain[8]. The specific activity of the alkaline phosphatase[9], acid phosphatase[9] and β-glucuronidase[10] of all fractions were compared (Table 1). The particulate fractions were diluted in a standard volume of 0·25 M sucrose and thoroughly mixed with an equal volume of 1 per cent deoxycholate, *p*H 8·4 (ref. 1). The resulting mixture is a micellar suspension allowing maximum expression of enzymatic activities. Protein was determined by the method of Lowry *et al.*[11].

Certain tentative conclusions can be drawn from Table 1. In agreement with Morton's findings[4], almost all (98 per cent) of the alkaline phosphatase is sedimented

Table 1

¶ Not measured in this experiment due to low yield. Results obtained from another experiment.

by centrifugation at 105,000*g*, indicating its close association with cell particles.

The microsome fraction has high specific activity when compared to nuclei, mitochondria–lysosomes or homogenate supernatant. On further fractionating the microsomes, it was found that microsomal membrane, as well as the ribosomes, have high alkaline phosphatase specific activity, while exhibiting minimum contamination by other fractions. The microsomal supernatant also contains alkaline phosphatase. However, on centrifugation at 130,000*g* for 3 h, this enzyme activity is almost entirely sedimented. The sediment consists of light microsomal membranes containing the highest alkaline phosphatase specific activity of any cell particle. These membranes have no measurable β-glucuronidase, as shown by Table 1.

Although the nuclear fraction appeared homogeneous by light microscopy, it is contaminated with other particles, as shown by the high specific activity of both acid phosphatase and β-glucuronidase. The lysosome-containing fraction has the highest acid phosphatase and β-glucuronidase specific activities, as expected. The high alkaline phosphatase specific activity of both the nuclear and mitochondria–lysosome fraction may be due in part to contamination by cell particles with high alkaline phosphatase content. However, the alkaline phosphatase activity is so high that it is probable that both these fractions contain intrinsic alkaline phosphatase. For all the contamination to be due to microsomes it would require 50 per cent of the protein of these fractions to be microsomal protein.

When the fractionation described here was performed using 0·18 mM calcium chloride, the results were qualitatively similar, although only 68 per cent of the alkaline phosphatase activity was recovered, presumably due to inhibition of enzyme activity by calcium ions.

The findings indicate that microsomal membranes contain most of the alkaline phosphatase associated with the microsome fraction. Although the nuclear and mitochondria–lysosome fractions were contaminated by other cell particles, their high alkaline phosphatase specific activity implies intrinsic localization within them.

We thank Dr. Salah Al-Askari and Dr. Felix Rapaport for their advice on fractionation techniques.

Qualitative Estimation of Erythrocyte Catalase by Starch-gel Electrophoresis

Erythrocyte catalase can be assayed in the usual quantitative way as well as by qualitative starch-gel and starch-block electrophoresis[1–3]. The electrophoretic method permits a more subtle characterization of its normal and abnormal properties. In comparative examinations of catalase from cord blood and blood samples of abnormal hæmoglobin carriers, no abnormal electrophoretic behaviour could be observed[3]. An atypical catalase was identified recently by a somewhat slower electrophoretic mobility in some members of a Caucasian family[4].

The principle of known electrophoretic assays consists of the negative iodine–starch reaction at the catalase location, thus forming white spots within the dark environment. The method given here utilizes hæmoglobin added in small concentrations to the starch gel as indicator of catalase. The presence of catalase prevents the peroxidative transformation of colourless *o*-dianisidine into the coloured product by action of hæmoglobin. Thus in one step the hæmoglobin fractions as well as catalase can be observed on a brown background.

For preparation of starch gel, 20 g of potato starch and 48 g of soluble starch are dispersed together with 90 ml. of *tris*-EDTA-borate-buffer, *p*H 9·0, and are added during constant stirring to 360 ml. of the same buffer boiling in a steam. When the starch becomes gel-like, 0·7 ml of a solution containing 5 g of hæmoglobin in 100 ml. are added, mixing it well with the hot gel. Following this the gel has to be evacuated by a water pump until no more air bubbles arise which could disturb electrophoresis. This gel is poured into the proper form, which can be cooled in a refrigerator after 0·25 h.

Hæmolysates are prepared in the usual way from erythrocytes washed three times in 0·9 per cent sodium chloride and shaken with carbon tetrachloride. For electrophoresis Whatman No. 3 *MM* paper cuttings 12 mm by 7 mm are soaked in the hæmolysate, blotted well between filter paper and placed into the proper gel position. In order to prevent drying of the gel liquefied paraffin (melting point 42°–44° C) is poured directly over it. Running time is 4–6 h at 60 m.amp, 400–500 V +12° C. Thereafter the gel is cut into layers 3 mm thick and is subjected to hæmoglobin staining (100 mg *o*-dianisidine in 200 ml. 96 per cent ethanol + 100 ml. McIlvaine buffer, *p*H 4·7+0·5 ml. 30 wt. per cent hydrogen peroxide).

The separated hæmoglobin fractions are indicated by a strong brown colouring (Fig. 1), while the hæmoglobin

Fig. 1. Demonstration of hæmoglobin and catalase in starch-gel electrophoresis, *p*H 9·0. Left, normal adult blood: middle, blood of a 4-week-old infant: right, purified liver catalase of the cow

added during gel preparation produces an even and slightly brownish to violet background. The locations of catalase are indicated by white areas. The mobility of catalase is determined by *p*H: at *p*H 9·0 it is somewhat higher than HbA_2; raising the *p*H produces a movement towards the cathode, lowering the *p*H a movement towards the anode. The width of the catalase fraction depends on its concentration: a reasonably bordered separation is obtained from concentrations found in 0·8–1·0 g per cent hæmoglobin solutions. The sensitivity of the assay, though of little meaning for a qualitative consideration, is limited by 100-fold dilution of a 15 g per cent hæmolysate.

The advantage of this method lies in the simple procedure as well as the simultaneous demonstration of hæmoglobin and catalase. On one hand, a qualitative judgment is obtained on both hæm proteins; on the other hand, the relative mobilities can be used for characterization of catalase.

PHYSIOLOGY

Drinking caused by Constriction of the Inferior Vena Cava in the Rat

Injection of osmotically effective solutes in hypertonic solution causes nephrectomized rats to drink enough water to dilute the injected solute to isotonicity, so long as the initial increase in osmotic pressure does not exceed about 15 per cent[1]. With intact kidneys, however, less water is drunk because the solute can be eliminated in hypertonic urine, though the degree of hypertonicity depends on the rate of urine flow[2]. If drinking water is withheld excretion is even more rapid.

Isotonic depletion of body fluid by bleeding or by peritoneal dialysis is also an effective stimulus of drinking[3,4]. After depletion by peritoneal dialysis large amounts of water may be drunk; there is also extreme antidiuresis and a fall in the amounts and concentrations of sodium and potassium in the urine. In the acute stages of depletion the body fluids may become profoundly hypotonic as a result of the water intake, but later this hypotonicity is rectified by the development of a marked preference for saline[5].

In this communication some experiments in which the inferior vena cava was ligated are described. Caval ligation results in a sharp diminution in venous return to the heart and a fall in cardiac output and might be expected to have similar effects on fluid metabolism as bleeding and peritoneal dialysis. Complete and sudden occlusion of the inferior vena cava above the renal veins and below the hepatic veins does not cause loss of consciousness in unanæsthetized animals, though mean arterial pressure is immediately halved. This fall does not persist, and the pressure gradually returns to normal over the next few days. Ascites does not occur, the procedure is well tolerated and such effects as there are appear transient.

Male albino rats weighing between 150 and 300 g were anæsthetized with ether. The inferior vena cava was approached through a small muscle splitting incision in the right loin and was completely ligated above the entry of the renal veins and below the hepatic and right adrenal veins. The animals were weighed and then placed in individual metabolism cages with water available but no food. Drinking was recorded continuously for 6 h, and at the end of this period the urine excreted was collected for analysis and the animals again weighed. Serum freezing points were measured in some instances to confirm that caval ligation alone had no effect on osmotic pressure. The control animals were subjected to a sham operation. In another group of experiments ligated and sham-operated animals were given various doses of 2 M sodium chloride intraperitoneally at the time of operation. Special care was taken to seal the wounds to prevent leakage of saline.

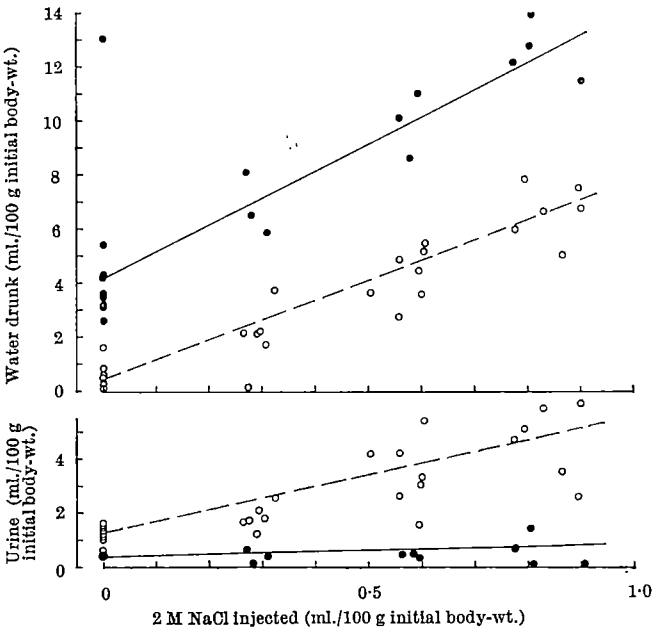

Fig. 1. Amounts of water drunk and urine excreted in 6 h by rats allowed to drink after injection of 2 M sodium chloride. ○, sham-operated; ●, caval ligation. The sloping lines were fitted by eye. Each point is one observation, except the urine of the uninjected ligated group which is a mean value

In the 6 h after operation the ligated rats drank more water and excreted less urine than the corresponding sham-operated rats (Fig. 1). Ligated animals generally started to drink within 30 min of operation, and even after the largest doses of saline, drinking was mainly completed in the first 3 h. The rate of drinking tended to decline exponentially. The failure of osmotic diuresis in the ligated group after hypertonic saline, and the very low urinary sodium and potassium, are shown in Table 1.

Table 1. Urine volume and amounts of sodium and potassium excreted in 6 h after injection of ligated and sham-operated animals with 2 M sodium chloride. Mean values of animals in Fig. 1 with the number of observations in parentheses

Sham-operated				Ligated			
2 M NaCl ml./100 g	Volume ml./100 g	Na μM/100 g	K μM/100 g	2 M NaCl ml./100 g	Volume ml./100 g	Na μM/100 g	K μM/100 g
(9) 0	1·16	75	171	(9) 0	0·4	26	30
(6) 0·292	1·82	474	231	(3) 0·288	0·39	18	18
(7) 0·575	3·48	863	234	(3) 0·582	0·43	23	27
(6) 0·845	4·7	1,225	309	(4) 0·823	0·59	47	66

The amounts of water drunk by the ligated rats injected with saline are comparable with the amounts drunk by nephrectomized rats after the same dose of saline, and since urine production was minimal, the water retained, as measured by the change in weight, was sufficient to dilute the saline to isotonicity.

If the effects of caval ligation on drinking are to be attributed to the failure to excrete the injected salt it might be predicted that caval ligation in nephrectomized rats would be without effect. This was tested by repeating the aforementioned experiments on bilaterally nephrectomized rats, the nephrectomy being performed at the same operation as the other procedures. There is certainly no significant difference between the changes in weight

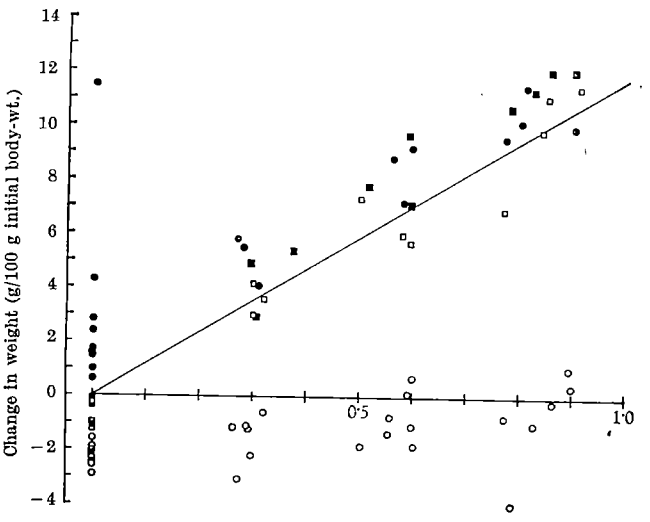

Fig. 2. Changes in weight in 6 h of rats allowed to drink after injection of 2 M sodium chloride. ○, sham operated; ●, caval ligation; □, nephrectomized; ■, caval ligation and nephrectomy. The sloping line delineates the changes in weight required to dilute the saline to isotonicity, assuming no excretion

of the nephrectomized group and the nephrectomized ligated group (Fig. 2), nor is there any obvious difference between both nephrectomized groups and the ligated groups with intact kidneys after the larger saline loads. Turning now to the groups which were not given saline, there is a significant ($P \simeq 0{\cdot}02$) difference between the changes in weight of the ligated group with intact kidneys and both nephrectomized groups, and a highly significant ($P < 0{\cdot}001$) difference between the ligated and sham-operated groups with intact kidneys.

The interpretation of these results is that caval ligation is an effective stimulus of drinking in rats with intact kidneys, but that when hypertonic saline is also given this effect is masked by the large amount of water drunk to neutralize the osmotic stimulus. Secondly, since caval ligation seems ineffective in nephrectomized rats, the kidneys play a part in the response, possibly by release of renin or some other renal factor such as that described by Asscher and Anson[6].

Nitrogen Balance Experiments: Some Theoretical Considerations

The method[1] for the determination of nitrogen balance indices (K) by measuring the slope of the line relating either absorbed or intake N to N balance has been well tried. The interpretation of the results depends on treating the experimental points as falling on a straight line in the region below nitrogen equilibrium, and values for K may be shown to be theoretically equal to values for either biological or net protein utilization (NPU) depending on whether data for absorbed or intake nitrogen are used. For example:

$$\text{N balance} = \text{endogenous excretion} + K \times \text{N intake} \quad (1)$$

$$\therefore K = \frac{\text{N balance} - \text{endogenous excretion}}{\text{N intake}} = \text{NPU} \quad (2)$$

However, it has recently been shown[2] that NPU varies with the concentration of protein in the diet (P) according to the equation:

$$\text{NPU} = b(1 - kP) \quad (3)$$

where b and k are constants. In view of the work of Allison and Anderson[1], we[2,3] took the view that below maintenance NPU was constant, but re-examination of the literature suggests that the efficiency of nitrogen utilization falls over the whole range of protein concentration and that the relationship plotted by the American workers should be slightly curvilinear. This does not invalidate nitrogen balance index as a method of assaying protein value since the slopes of the lines would be similar, but raises some points of theoretical interest. For example, it is possible to explain why some values for K and indeed some biological values would indicate efficiencies of retention that are greater than 100 per cent. Several such values appear in the literature, and one might suspect that others have been found but rejected as apparently impossible.

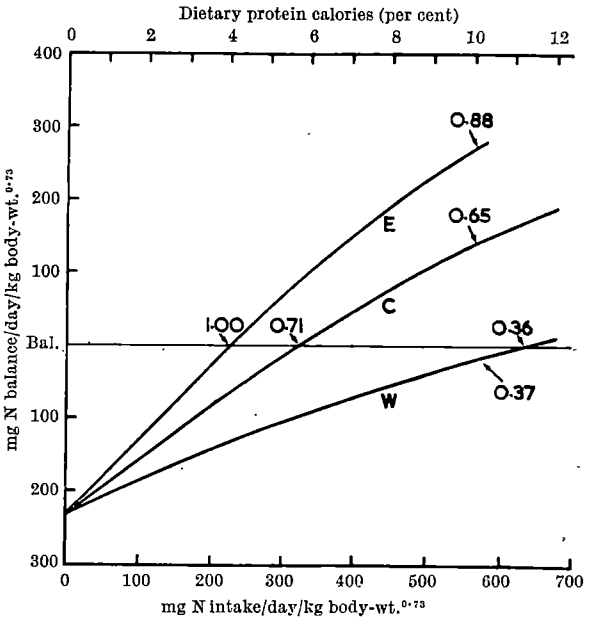

Fig. 1. Relationship between nitrogen balance and nitrogen intake for three proteins (egg, E; casein, C; wheat gluten, W), to be expected when caloric intake is twice basal calories/day. The numerals indicate the slopes of the curves at the points indicated

Fig. 1 shows for three proteins the relationship between nitrogen balance and nitrogen intake expected on the basis of equations 1, 2 and 3*. It is assumed that the animals were fed a number of calories per day equivalent to twice the basal metabolism, and the percentage of protein in the diets is shown; these conditions are similar to those chosen by Allison and Anderson[1]. It will be seen that the lines depart from linearity to an extent less than would be detected experimentally. The upper curve represents egg protein which has been shown[5] to have a biological value of 100 when the diet contains 4 per cent protein. In order to obtain a slope of unity at this percentage, it is necessary to assume retentions greater than 100 per cent from diets containing less than 4 per cent egg protein. Such values have been reported; for example, a mean of 115 from 10 determinations for egg white[6] and values of 128 for an amino-acid mixture[7]. Further evidence is supplied by actual demonstrations[4] of a curvilinear relationship between nitrogen balance and nitrogen absorbed for egg protein with a maximum slope of 1·23. These high values

* By inserting values for NPU given by equation (3) for K in equation (1), the relationship between nitrogen balance and nitrogen intake is seen to be of the form: N balance $= AP - kAP^2 -$ endogenous N, where A is a constant ($b \times$ caloric intake/25). This equation is of the same form as that presented by Forbes, Vaughan and Yohe (ref. 4).

are in agreement with protein scores as usually defined but admitting values greater than 100. According to food tables[8], egg has an excess of all the essential amino-acids over the reference pattern given by the Food and Agriculture Organization[9] and would score 114 on its content of tryptophan.

The physical meaning of nitrogen retentions of more than 100 per cent needs explanation. In determining the nutritive value of proteins we are concerned with the instantaneous effect of the diet on the animal, and observe the fate of the nitrogen it consumes; losses of urinary or fæcal nitrogen of endogenous origins are allowed for in the calculations made (equations 1 and 2). It is generally assumed that these losses are constant irrespective of the diet consumed, but it is now known that they may be reduced in certain cases. For example, body protein is spared by diets containing low levels of egg protein[10] when rats excrete less nitrogen than on a non-protein diet. Similar data have been obtained with dogs[11]. Non-protein diets supplemented with methionine also reduced nitrogen loss[10,11]. Reductions of endogenous loss result in calculated efficiencies greater than 100 per cent. Since such diets promote the re-cycling of amino-acids derived from the tissues, it is reasonable that they are rated accordingly. Absorbed amino-acids enter the metabolic pool derived from the catabolism of tissue proteins and it is the amino-acid balance of the resultant mixture which determines the rate of anabolism. Since the tissue proteins are limited by the sulphur amino-acids, at low levels of protein intake the pool may be effectively supplemented with methionine. Similarly, as the tissue proteins have a relatively high proportion of lysine they will supplement diets low in this amino-acid: this would account for the positive NPU values obtained with diets totally deficient in lysine[12,13].

The foregoing considerations show that treating the results of Allison and Anderson[1] as a linear or curvilinear relationship makes little difference to the nitrogen balance indices obtained. It is also clear that NPU values rise as the protein concentration is lowered below that required for maintenance, but this fact does not alter the validity of the equations[2,3,14] derived for the prediction of protein values. The evidence shows that these equations now apply below maintenance as well as above. However, the increased values of NPU below maintenance make little difference to net dietary protein values which are low and of small practical interest.

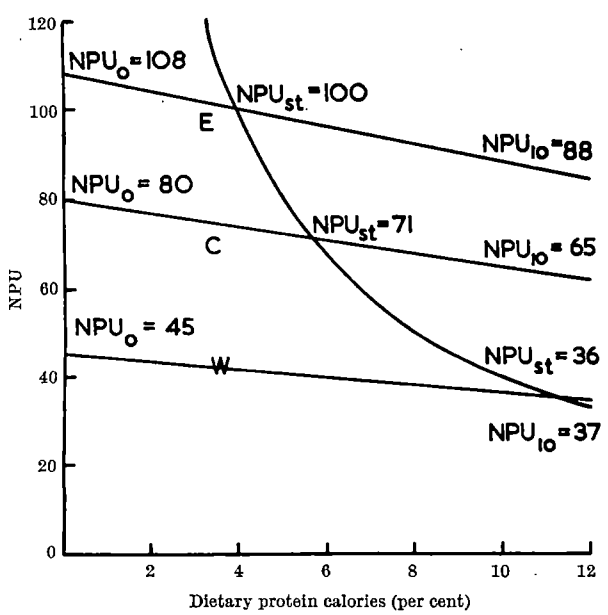

Fig. 2. Relationship between net protein utilization and protein concentration for three proteins: egg (*E*), casein (*C*) and wheat gluten (*W*). The numerals indicate the values for NPU a specified protein concentrations

The foregoing observations are of practical importance, as in order to predict the protein values of diets from chemical data the relationship between protein score and NPU must be evaluated. Thus, it is usual to determine diets containing 10 per cent protein (NPU_{10}) and to calculate the value of NPU at maintenance (NPU_{st}): an alternative parameter is the intercept of equation (3) on the NPU axis (NPU_0). The relationship between these values is illustrated in Fig. 2 using data obtained for egg, casein and wheat gluten. It is clearly necessary to specify in all cases which of the values for NPU is being used. It may well be that NPU_{st} and NPU_0 correlate with protein scores better than NPU_{10}, which was chosen by Block and Mitchell[15]. Certainly the design of an 'ideal' amino-acid pattern for calculation of protein scores should take the differences between the values into account.

It will be noted that the experiments of Allison and Anderson[1] differ from those of Mitchell and Carman[5] and from those of Munro[16]. In the work of Allison and Anderson[1] the caloric intake was fixed and thus the protein intake and concentration varied. Mitchell and Carman[5] fixed the concentration of protein and the caloric and protein intake varied. On the other hand, in the work described by Munro[16] the protein intake was fixed and the caloric intake and protein concentration varied. Apparent discrepancies between the results of these experiments are resolved by our theory of protein metabolism[17], which takes into account the interrelationship between the various dietary factors that influence nitrogen balance[18].

Temperature Discrimination in the Skin

Thermoreceptors reported in the skin of the cat, rat and dog[1–3] had properties similar to the thermoreceptors found in the tongue[4]. The afferent fibres, however, had low conduction velocities characteristic of non-myelinated axons. The receptors fell into two categories: those excited by a rise and those excited by a fall in cutaneous temperature, above or below the neutral temperature of the skin. At certain temperatures each of the fibres was firing steadily and when tested would continue to respond at a nearly constant rate of discharge for 30 min or longer. The very low conduction velocities of all the afferent fibres, less than 1·5 m/sec, was difficult to fit with results based on psycho-physical and nerve-block techniques in man, which indicated that most of the afferent fibres mediating cutaneous thermal sensations

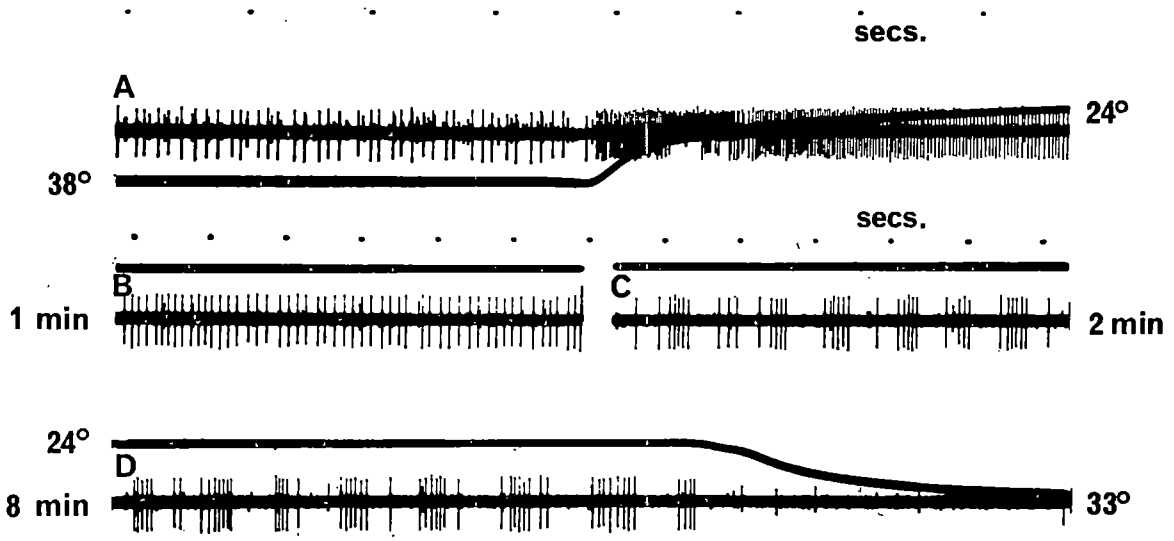

Fig. 1. The discharge of impulses in a cold receptor in response to lowering the temperature of the skin. In record *A*, the upper trace shows the impulses in the fibre and the lower trace shows the temperature of the skin. Initially the skin had been held at 38° C and just before the start of the upper record was allowed to cool slightly. This produced the regular discharge of impulses. The water flowing through the thermode was then suddenly switched to 24° C. As the cutaneous temperature was falling there was an acceleration of the discharge which was maximal (peak 120/sec) before the skin had reached the new steady temperature. *B*, 1 min after the change the skin temperature was still falling very slowly and the discharge was still regular. *C*, 2 min after the change the temperature was steady and the grouped discharge had made its appearance. *D*, 8 min later the grouped discharge was still present and disappeared when the temperature was raised. The time marks are at 1-sec intervals

had conduction velocities faster than 4 m/sec[5], although Landau and Bishop[6] have more recently brought forward evidence that in man, too, some thermal sensations can be mediated by non-myelinated fibres in peripheral nerves.

Monkeys were used in the experiments reported here and the thermoreceptors found had several differences in properties from the thermoreceptors in the cat, rat and dog. The monkeys were anæsthetized with chloralose and 'Nembutal' and the afferent fibres were dissected from either the median nerve or the musculocutaneous nerve in the upper arm. The cutaneous temperatures were controlled by circulating water, controlled to $\pm 0{\cdot}02°$ C by a thermostat, through a closed metal cylinder, 10 mm diameter (the 'thermode'), which rested on the skin. The temperature was registered by a thermistor bead mounted on the surface of the thermode in contact with the skin.

The endings of the afferent fibres were either in the hairy skin of the radial side of the forearm or in the glabrous skin of the palm, thumb, first or second finger. The receptive fields, measured with a thermal stimulator which had a tip diameter less than 75μ, were always small, ranging from 0·25 to 0·6 mm^2. Each fibre ended in only one temperature-sensitive spot in the skin. These small areas of maximal thermal sensitivity may correspond to the cold spots in human skin first reported by Blix[7].

The sizes of the afferent fibres were assessed by measuring the conduction velocity in individual fibres from a pair of electrodes placed distally, either on the nerve trunk or the fibre-ending in the skin, to the nerve filament on the proximally placed recording electrodes. Measurement from the skin invariably gave a lower value for the velocity than for stimulation of the nerve trunk, as reported previously for the cat[1], probably due to tapering of the axon as it approaches its endings in the skin. The conduction velocities of the 14 fibres measured were, with two exceptions, in the range 3·6–15 m/sec so that the fibres were myelinated, with diameters ranging from about 1–3μ. The exceptional fibres had conduction velocities below 1·5 m/sec and were probably non-myelinated, with diameters below 1μ. The monkeys thus differs markedly in this respect from the cat, rat and dog in which all the thermoreceptors examined in detail have had afferent fibres with conduction velocities below 2·5 m/sec, that is, were non-myelinated fibres, less than 1μ diameter.

All 19 thermoreceptors examined as single units in the present experiments were excited by lowering and inhibited by raising the cutaneous temperature. No receptors excited by small increases in skin temperature were found although in multi-fibre preparations not examined in detail there were some fibres comparable to the heat receptors of the cat[1]. A possible reason for the failure to find sensitive 'warm' receptors is that they are all innervated by non-myelinated axons. The peak frequency of discharge on suddenly cooling the skin, by lowering the temperature of the thermode resting on the surface from 40° C to 20° C, was about 150 impulses/sec. A striking and characteristic property of these cold-sensitive fibres was the grouping of impulses into bursts separated by intervals of silence (Fig. 1). This pattern of discharge was most conspicuous when the cutaneous temperature was steady, but was also recorded when the temperature was changing. The number of impulses in a burst varied at different times between 2 and 8, but at any particular temperature was usually constant or fluctuated by only one or two impulses. The bursts of impulses lasted from 1/10th to about 1 sec and the interval between bursts had similar durations. Whenever the temperature either rose or fell, even if the rate of change was less than 0·05° C/sec, the grouped discharge was altered and eventually disappeared to be replaced either by a more steady stream of impulses or by silence (Fig. 1*A* and *B*). The grouped discharge returned when the temperature was once again steady (Fig. 1*C*). The frequency of the adapted discharge depended on the temperature of the skin and was maximal, not usually greater than 120/sec for each fibre at some temperature in the range 20°–35° C. Many of the fibres had a regular grouped discharge of impulses at cutaneous temperatures above 35° C but not above 40° C, so that they were active at temperatures above the normal temperature of the skin. On two occasions there was a discharge above 46° C which corresponds to the paradoxical discharge reported by Dodt and Zotterman[8]. Although a fibre might be silent at the higher temperatures it would nevertheless fire when the skin was cooled to a temperature above that at which there was an adapted discharge, and in these conditions the fibre would become silent again after a few seconds.

Exact measurements of the thermal sensitivity were not made, but all the fibres could be excited by temperature changes of less than 0·5° C and the grouped

discharge could be altered by much smaller changes than this, less than 0·05° C/sec. A comparison of the thermal sensitivity with the threshold of cold spots in human skin revealed a comparable sensitivity at threshold.

None of the receptors could be excited by innocuous mechanical stimulation such as moving hairs, stroking or pressing on the skin. Some units were excited by pressing a small probe firmly on the skin using a force (5 g wt.) about 2,000 times the threshold of the most sensitive cutaneous mechanoreceptors. The thermal and mechanical receptive fields were coincident so it is likely that the mechanical stimulus was acting on the temperature-sensitive elements.

The sizes of the receptive fields, the thermal sensitivity and persistence of discharge at constant temperature taken together with size of the afferent fibres suggest that if, as seems likely, man and monkey have similar cutaneous receptors, then the receptors described here have a crucial role in thermal sensation. They are probably the cutaneous cold receptors, specifically signalling thermal conditions in the skin and thus the environment. Hensel and Boman[9] have recorded from one similar afferent unit in human experiments. Whether warm receptors also exist, that is, afferent nerve-endings specifically excited by small rises in skin temperature, cannot be decided on the present results. They have been described in other animals and the failure to find any may result either from the actual paucity of warm receptors, and indeed warm spots are distributed much less thickly in human skin than are the cold spots, or because the receptors are innervated by non-myelinated axons.

This work was done during the tenure of a Locke research fellowship of the Royal Society.

Increase of Muscle Permeability to Aldolase in Several Experimental Atrophies

After denervation the whole sarcolemma becomes as sensitive to acetylcholine as the neuromuscular junction of the normal fibre[1]. An increase of the rate of exchange of ^{24}Na and ^{42}K between interior and exterior of the denervated muscle has been observed[2] and this increase can be attributed to an increase in sarcolemma permeability. From this it could be supposed that denervation would also affect other properties of the sarcolemma. It was, therefore, decided to determine whether the sarcolemma of the denervated muscle showed an increase in permeability to protein molecules, because it is known, mainly from the data of Zierler[3–7], that aldolase, and probably other glycolytic enzymes, moves out of the fibres during incubation of normal skeletal muscle of rat *in vitro*, probably by diffusion. This work has been extended to other conditions leading to atrophy of the muscle, namely, tenotomy, partial ischæmia and caloric deprivation.

Extensor digitorum longus muscle from young albino rats (body-wt. between 50 and 80 g) was used throughout. Denervation was performed by excising 1 cm of the sciatic nerve at the level of the hip joint. For tenotomy, the proximal tendon of the muscle was severed. Partial ischæmia was caused by ligature of the femoral artery in the proximal region of the thigh. Caloric deprivation was obtained by giving to the rats one-third, by weight, of the amount of food consumed by controls of the same initial weight, fed ad libitum. The contralateral normal muscle was used as a control in the experiments involving denervation, tenotomy, or ligature.

Table 1. Mean Differences between Normal and Atrophic Muscle in Aldolase Efflux and Total Aldolase Content

Values represent the mean result ± *S.E.M.*; number in parenthesis
*Difference significant at the $P < 0·05$ level.
†Difference significant at the $P < 0·01$ level.

In nearly all the experiments the muscle was incubated for 1 h at 38° C, in standard Warburg bottles, in 5 ml. of a modified Krebs–Ringer glucose-phosphate solution, *p*H 7·4 (ref. 4). At the end of the incubation period aliquots of the fluid and of the homogenate of muscle (prepared in a Potter–Elvehjem apparatus) were immediately assayed in duplicate for aldolase according to Sibley and Lehninger[8]. Effluent aldolase activity is expressed as percentage of total aldolase activity (residue in the muscle + effluent).

The results (Table 1) show that a significant increase in aldolase efflux *in vitro* takes place after denervation as well as after tenotomy and ligature of the femoral artery, whereas in the fourth type of atrophy, that due to caloric deprivation, the opposite effect is observed, namely, a decrease of the efflux. The increase in permeability is roughly similar in the three types of atrophy, but differs notably in the time of onset. In the case of tenotomy it is already evident after 12 h, while after denervation it is apparent at 2 days. In both conditions it precedes the decrease in weight of the affected muscle, whereas in the case of ischæmia, the increase in efflux is delayed and follows the decrease in weight of the muscle.

On the basis of the relation found by Zierler[4] between weight of the muscle and aldolase efflux, it could be supposed that, at least in the more advanced stages of atrophy, the increased efflux could be attributed to the decrease in weight of atrophic muscle. However, calculation of the correlation coefficient between weight and efflux did not show any significant correlation in the first three types of atrophy. These results are, therefore, in agreement with the hypothesis that, in muscular atrophy due to denervation, tenotomy and ischæmia, the sarcolemma is altered and that this alteration causes an increased efflux of aldolase.

The difference in aldolase efflux from denervated muscle in comparison with controls was not altered by lack of glucose, anoxia, a high potassium medium or insulin, although increased efflux was observed in the atrophic and the normal muscle. This suggests that the increase in permeability observed in atrophy is secondary to modifications of the metabolism of muscle. In fact, it could be expected that, if the membrane alteration were primitive,

the reaction of the sarcolemma of the pathological muscle would be different from that of the control, as suggested by Zierler[9].

It is clear from our results that there is no relation between acetylcholine hypersensitivity and increased efflux of aldolase in the denervated muscle. The increase in permeability is already present two days after denervation, when there is only a beginning of the extension of the area of sensitivity to acetylcholine. Its full development takes at least a week[1]. Furthermore, the increase in the efflux of aldolase is also evident after tenotomy, and in the ischæmic muscle. It is known that in the atrophies of disuse there is no clear increase in sensitivity to acetylcholine[10].

A further difference between the various types of atrophy investigated is evident in the total aldolase activity, which is lowered in the denervated muscle much more than the fresh weight, whereas in the other types of atrophy its decrease is parallel to that of the weight.

An increased permeability of the muscle fibre to aldolase has been observed directly[9] in the case of the hereditary muscular dystrophy of mice. The recent data of Dowben and Zuckerman[11] point to an increased permeability of muscle after local X-ray irradiation. Our data provide further evidence of an increase in permeability of muscle cells as a general response to noxious stimuli and metabolic alterations.

PHARMACOLOGY

Influence of Hypothermia on the Radioprotective Effects of β-Mercaptoethylamine

In 1951 Bacq *et al.*[1] showed that β-mercaptoethylamine (MEA) could protect mice against ionizing radiation. Essentially, three mechanisms for the protective action of this compound have been considered. They are pictured as scavenging free radicals[2,3], lowering the oxygen tension in tissues[4,5], or forming complexes with sulphur-containing proteins by means of —S—S— bonds[6,7]. In previous work we showed that the protective action of MEA is increased by surface-active substances and by hyaluronidase[8].

The radioprotective action of MEA seemed also to be enhanced by hypothermia. It is well known that hypothermia has a radioprotective effect by inducing hypoxia[9]. It is the purpose of this communication to establish whether the effect of MEA under the conditions of hypothermia is greater than of MEA alone and to investigate the mechanism of the MEA action.

One hundred and twenty *A/Jax* male mice weighing 22–25 g and aged 60–70 days were used throughout. Sixty animals were used for controls with physiological NaCl-solution and MEA. Another 60 animals were given an injection of a mixture of 'Hydergin' (2 mg/kg body-wt.), 'Propaphenin' (5 mg/kg body-wt.) and 'Dolcontral' (4 mg/kg body-wt.), and then cooled down to 20°–25° C by placing them in a room with normal temperature (+20° C) for 60 min and then in a cold room (+2° C) for 30 min. A further 30 animals were irradiated immediately. Another 30 received, 15 min before irradiation, an intraperitoneal injection of MEA (3 mg/1 ml. physiological NaCl solution). The mice were irradiated with 800 r. (170 kVp., 22 m.amp, 0·5 mm Cu- and 1·0 mm Al-filter, 85 r./min). The statistical analysis was done by using the χ^2 test with the correction of Yates[10].

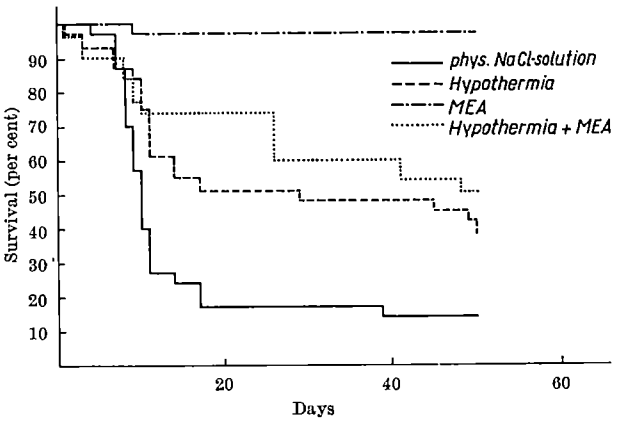

Fig. 1. The effect of hypothermia on the radioprotective action of MEA in male *A/Jax* mice

Fig. 1 shows the survival curves obtained for mice injected with physiological NaCl solution, MEA, or under hypothermia alone, or in the combination of hypothermia and injection of MEA.

It can be observed that the protection afforded by hypothermia alone is lower than the protection of MEA alone. The combination of hypothermia and MEA shows no potentiating or additive effect. On the contrary, Table 1 shows that the action of MEA under the conditions of hypothermia is lowered in such a way that no significant difference between hypothermia alone and hypothermia in combination with MEA is demonstrable.

Table 1

	Control (NaCl)	Hypothermia alone	MEA alone	Hypothermia +MEA
Control (NaCl)	5	++	+++	++
Hypothermia alone	14		+++	0
MEA alone	29			++
Hypothermia + MEA	18			

0, Difference not significant; +, difference significant ($P < 0.05$); ++, difference significant ($P < 0.01$); +++, difference significant ($P < 0.001$).

These results suggest that in the hypothermic conditioned hypoxic mice the radioprotective effect of MEA is not evident. The failure to demonstrate a significant additive protective action when MEA and hypoxia were combined is taken to indicate that MEA and hypoxia act at some stage through a common pathway for radio-protection. This view was substantiated by Patt, Blackford and Straube[11], who found that hypoxia and cysteine had no additive effect in diminishing the radiosensitivity of rabbit thymocytes, and by Weiss[12], who showed that cysteamine did not afford a significant radioprotection to the hæmopoietic system of severely hypoxic mice.

To explain the fact that MEA is not effective in protecting mice when the oxygen tension is lowered it can be assumed that MEA takes part in the oxygen-dependent production of free radicals. Ormerod and Alexander[13] showed by electron-spin resonance investigations of irradiated salmon sperm head DNA that the radioprotective effects of cysteamine were brought about by the transfer of a hydrogen atom from the SH-group of cysteamine to the radicals produced in DNA.

We may therefore assume that MEA reacts with radiation-induced radicals $R\cdot$ of biologically important molecules in competition with oxygen in such a way that the peroxidation of the radicals is prevented.

$$RH \text{---}\sim\rightarrow R\cdot + HS{\cdot}CH_2{\cdot}CH_2{\cdot}NH_2 \rightarrow RH + NH_2{\cdot}CH_2{\cdot}CH_2{\cdot}S\cdot$$

$$RH \text{---}\sim\rightarrow R\cdot + O_2 \rightarrow RO_2$$

This hypothesis will be tested further by investigating the quantitative relations between lowered oxygen tension and the concentration of MEA in the tissues on the radiation sensitivity of hypothermic mice.

Semi-automatic Transfer of Volatile Liquids to Paper Chromatograms

THE recent publication of a device for applying liquids to paper chromatograms[1] prompts this report of a simple arrangement for the reproducible transfer of small volumes which is in routine use in this laboratory for the application of steroid standards to paper chromatograms. It consists of a lambda pipette clamped in the vertical position with the pipette tip firmly against the surface of the chromatography paper which is supported on a perforated metal disk. A stream of compressed air for drying passes through holes in the metal disk against the lower surface of the paper (Fig. 1). In practice the pipette is filled with solvent and positioned while keeping a finger over the upper orifice to prevent leakage. Gradual transfer of solvent to paper begins when the finger is released. A Medtec Spotting Device was employed, but a simpler device for support of the paper and delivery of a gas stream would serve the purpose.

Experiments were performed with a variety of solvents (100–500 μl. volume) containing Sudan III as indicator, together with Whatman No. 2 chromatography paper and compressed air stream at room temperature. The spots which occurred using chloroform, benzene, ethyl acetate, or dichloromethane had diameters of 7 mm or less, while those with methanol were less satisfactory (8 mm diameter). Unsatisfactory results were obtained with water, due to tearing of the paper or spread of the solvent over a large area despite attempts to hasten drying by use of an infra-red lamp.

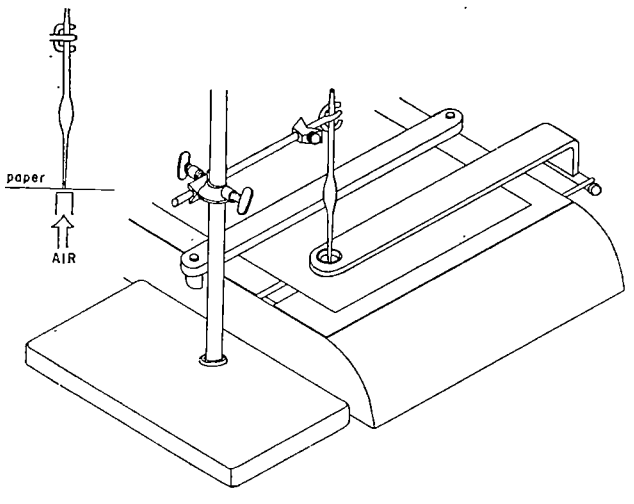

Fig. 1. Device for transfer of liquids to paper chromatograms

The time required to deliver 500 μl. chloroform was 7·5 min, benzene 14 min, and ethyl acetate 23 min. Transfer of solute to the metal disk is negligible provided the air stream is moderately vigorous and drying is effective. This device is applicable to wide chromatography paper, and semi-automatic delivery allows several chromatograms to be spotted in parallel if desired. The chief limitation appears to be the inability to handle large solvent volumes. Our spots appear to be slightly larger than those reported by Clarke and Sowter[1], perhaps because we used an air stream at ambient temperature, a choice which was dictated by the thermolabile nature of the solutes.

This investigation was supported by U.S. Public Health Service research grant *AM*–06607 and training grant 2*A*–5230, National Institute of Arthritis and Metabolic Diseases, and by the Oregon Heart Association.

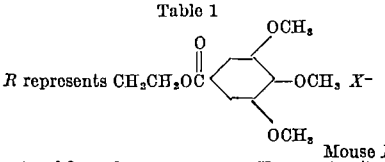
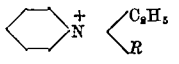
Inhibition of Synthesis of Acetylcholine by Some Esters of Trimethoxybenzoic Acid

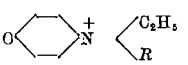
HEMICHOLINIUM (HC-3) has been shown to possess a strong inhibitory effect on acetylcholine (ACh) synthesis in nervous tissue which can be effectively antagonized by choline[1–6]. Similar activity, though to a lesser degree, has been demonstrated in tetraethylammonium (TEA)[7,8]. Replacement of the ethyl group of TEA by methyl, propyl or butyl results in a significant reduction of the inhibitory activity. Recently, we have demonstrated that troxypyrrolidinium (ethyl-2(3,4,5-trimethoxybenzoyloxy) ethyl pyrrolidinium iodide) possesses hemicholinium-like activity but is less toxic[9]. In the work recorded here, a series of trimethoxybenzoic acid esters are compared to determine the structure/activity relationship.

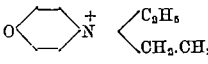
As shown in Table 1, the common feature in all compounds is the 'aminoethanol' moiety:

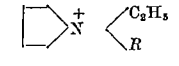


where the nitrogen is quaternized and the oxygen is linked to carbon which is in the carbonyl form. These compounds produce the characteristic toxic features of HC-3 (muscular weakness and respiratory depression at sublethal doses and respiratory paralysis followed by asphyxial convulsions at lethal doses). The LD_{50} (intraperitoneal) for mice, estimated by the method of probits[10], is shown in Table 1. Like HC-3, the toxic effects of all the compounds, with the exception of trimethylammonium (I), the morpholino derivatives with propyl (V) and butyl (VI) ester linkage, could be effectively antagonized by choline. The optimal protective dose of choline (100 mg/kg) raised the LD_{50} value 2–3 times. The compounds produced failure of transmission in the cat's superior cervical ganglion stimulated presynaptically at high frequency (20 shocks/sec). The ganglia lost 60–70 per cent of the preformed stores of ACh when stimulated for 30 min in the presence of triethylammonium (troxonium-









II) or pyrrolidinium derivative (troxypyrrolidinium-VII) at a dose of 200 μg/kg/min (intravenous). Loss of the ganglionic ACh could be prevented by simultaneous administration of choline. The compounds also possess some post-synaptic component in their action as indicated by reduction in the ganglionic stimulating effect of ACh. The morpholino derivative with the butyl ester linkage (VI) was the most potent in this respect.

Relative ability to inhibit ACh synthesis was investigated in minced brain preparation of mice incubated at 37° for 1 h in eserinized-bicarbonate Locke solution (*p*H 7·4: 95 per cent oxygen : 5 per cent carbon dioxide) as described by Bhatnagar and MacIntosh[8]. The test substance dissolved in the medium was added to the incubate to make a final concentration of 0·01, 0·1 or 1 mM. Two samples without the drug served as control, while two samples similarly prepared but not incubated were used for estimating ACh at zero time. Free and bound ACh (cf. ref. 8) was estimated by the cat's blood pressure method[11]. The 'total' ACh synthesized, which represented the net increase in both free and bound forms of ACh during the period of incubation, was determined and the ED_{50} for each compound was calculated (Table 1). Under our experimental conditions the amount of total ACh synthesized in absence of test substance was 12·3 ± 0·8 μg/g of wet brain tissue in 1 h, of which about one-third was in the free form.

All compounds except the trimethylammonium derivative (I) were found to be potent inhibitors of ACh synthesis. Replacement of the trimethylammonium group with triethylammonium, pyridinium (III) or morpholinium (IV) led to about 30-fold increase in the inhibitory activity. This effect became even more pronounced when the trimethylammonium group was replaced by the pyrrolidinium group (VII). The latter compound was 6–8 times as potent as the triethylammonium, pyridinium or morpholinium derivatives and possessed one-half to one-third the activity of HC-3. In addition to the quaternary *N* group, length of the ester link considerably influenced potency of the compounds. For optimal activity ethyl ester link was found to be essential (IV), as replacement of it with propyl (V) or butyl (VI) led to a progressive decline in activity. The anionic part of the molecule was of little significance.

Table 1

No.	Structural formula	X^-	Mouse LD_{50}* (mg/kg, i.p.)	ED_{50} (μM)†
I	$(CH_3)_3.\overset{+}{N}.R$	Tosylate	400 (376–426)	2,000
II	$(C_2H_5)_3.\overset{+}{N}.R$	Tosylate	23 (20–27)	60
III		I-	24 (23–25)	85
IV		I-	33 (30–37)	60
V		Tosylate	35 (31–40)	300
VI		Tosylate	63 (58–69)	600
VII		I-	32 (28–36)	10
	HC-3		0·18 (0·17–0·2)	4

* Sixty animals used for each compound. Ninety-five per cent confidence limits in parentheses.
† Concentration producing 50 per cent inhibition of ACh synthesis in mouse minced brain. Each figure represents an average of two experiments.

Release of ACh from the tissue to the medium was not significantly affected except by troxypyrrolidinium (VII) and the morpholino derivative with the ethyl ester linkage (IV), where at the highest concentration (1 mM) the ratio of free to bound ACh was reduced from a control value of 0·39 to 0·06.

The inhibitory effect could be reversed by addition of choline to the incubation medium. Investigations with troxonium (II) and troxypyrrolidinium (VII) showed that the concentration of choline required to reverse completely the inhibitory effect was about ten times the molar concentration of the compound. Activity of choline acetylase, the enzyme which catalyses the transfer of acetyl radical from acetyl-coenzyme *A* to choline, was not significantly affected.

These investigations show that among the compounds investigated pyrrolidinium derivative (VII) was the most potent inhibitor of ACh synthesis. For optimal activity the ethyl ester linkage was found to be essential while the anionic part of the molecule was of little significance. They appeared to act in a manner identical to that of HC-3, that is, by competing with choline for the intracellular sites of acetylation or with ACh for the storage sites.

PATHOLOGY

Production of *Trypanosoma cruzi* Cysts *in vitro*

Trypanosoma cruzi, the causative agent of American trypanosomiasis or Chaga's disease, has been found to produce cysts readily in culture if the medium is treated with a urease preparation. These forms resemble closely the description of cysts of some trypanosomes in their insect hosts[1–3].

Routine cultures of either the Brazilian or Corpus Christi strains of *T. cruzi* were made in screw-capped tubes containing a liquid medium. Each tube consisted of 5 ml. of 'Trypticase Soy Broth' (BBL) which had been enriched with 0·05 ml. of citrated human blood (outdated blood bank material). To start a fresh culture, 0·5 ml. of culture, between ten and fifteen days old, was added to this medium. The cultures were kept at room temperature. The usual forms of *T. cruzi* in culture were regularly obtained in this medium. A slightly modified medium, using serum and hæmolysed material made cell-free by centrifugation, was also used.

Two hundred mg of a crude urease powder (jack bean urease, 2 × National Formulary (U.S.A.), from Mann Research Laboratories, Inc., New York 6) was suspended in 10 ml. of twice-distilled water and the insoluble portion was centrifuged. The clear supernatant was sterilized by passage through a Selas filter of 03 grade porosity. Volumes ranging from 0·01 ml. to 0·1 ml. of this preparation added to fresh cultures of *T. cruzi*, as described above, and kept

at room temperature, produced cysts in about five days. As little as 10 μg of the urease powder per ml. of culture appeared to be sufficient, while 1 μg per ml. did not have this effect. Cyst formation was obtained in concentrations up to 500 μg of urease per ml., but with 1 mg/ml. it did not occur. Incubation at 37° C was unsatisfactory. Heating the urease preparation for half an hour in a 99° C water bath destroyed its cyst-inducing property.

The first effect of the urease preparation on the flagellates was to slow them down. The cells gradually increased in size and became highly granular. In a few days a structure resembling a vacuole, situated centrally or eccentrically, became very prominent in many of the organisms. Some of these organisms, now mostly spherical in shape, were found to contain a number of flagellated daughter cells within the vacuolar space. These were seen "writhing and twisting over each other within the enveloping periplast like a bunch of eels in a sack", to use the phraseology of Minchin and Thomson[1]. The area between the outer limits of the organism and the vacuole was clearly visible and appeared as a cyst wall of considerable thickness in the living state. Single cysts were observed; but the tendency was to form clusters in this medium. They were found to be at different stages of development and in different sizes. The cysts measured 10–25μ in diameter. Fig. 1*a* shows a cluster of cysts at the top; and below, a single cyst at the right, and a pair at the left. Half a dozen flagellates were in motion inside the upper cyst of the pair (arrow) at the time this picture was taken. Some of the amorphous structures are debris from the culture medium, in and out of focus. Fig. 1*b* was obtained by pressing down a group of cysts. Two organisms clearly show the thick, granular cyst wall around the vacuoles. These were all from a culture two weeks old.

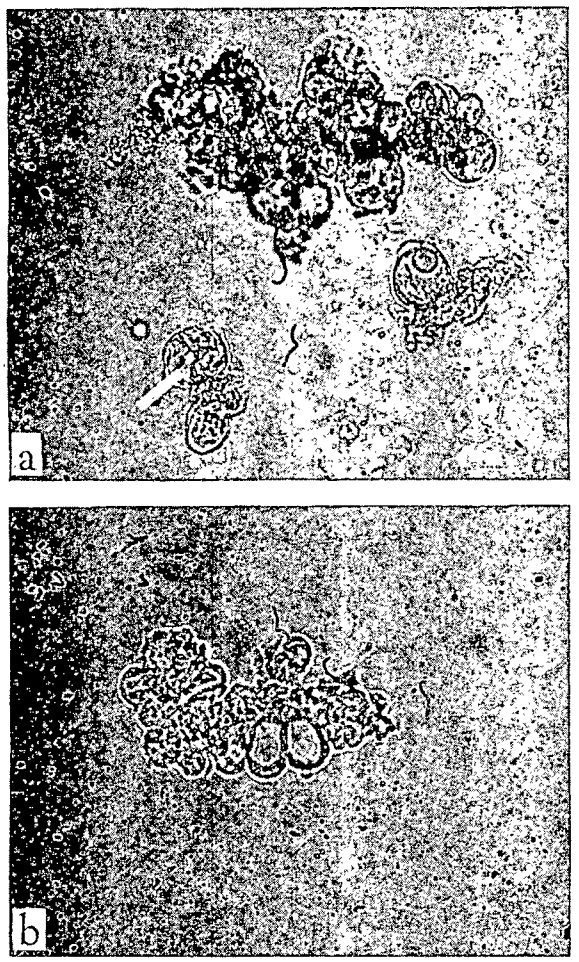

Fig. 1. Cyst formation in *Trypanosoma cruzi*. (*a*) Grouped and isolated cysts. About six flagellates were in motion inside the cyst, indicated by the arrow. (*b*) Gentle compression of cysts shows the thick granular cyst wall in optical section

Further work is in progress to determine whether this effect is specifically due to urease or to some other factor present in the crude preparation. Steinert[4] found urea to be the factor responsible for the transformation of the crithidia of *Trypanosoma mega* into its trypanosomal form.

IMMUNOLOGY

Effect of Actinomycin C on Immune Responses *in vivo*

SEVERAL workers have reported that the actinomycins do not suppress immune responses *in vivo*[1–4]. Wust *et al.*[5] found that actinomycin *D* injected into rats at the same time as sheep red cell antigen caused a short delay in appearance of the immune response, but did not affect the maximum antibody level reached. Butler[6] reported a slight depression of the secondary response to diphtheria toxoid on administration of actinomycin *D*. Nathan *et al.*[3] report actinomycin *D*, but not actinomycin *C*, active in their screening test. Actinomycin *D* has been found an effective inhibitor of antibody synthesis *in vitro*[7,8].

According to Reich[9], the actinomycins inhibit DNA-directed RNA synthesis at low concentrations, but have little effect on DNA synthesis except at high concentrations. Inhibition of RNA synthesis is dependent on the binding of actinomycin to the guanine moiety of DNA. The experiment described here was performed in an attempt to locate the period of messenger RNA production in the synthesis of antibodies to sheep red cell antigen.

On day 0, fifteen groups of male *A2G* mice (15–22 g body-wt.) and a control group were given 0·2 ml. of a 5 per cent sheep red cell suspension in saline intravenously. On each of days −7 to +7 one group of mice was injected intravenously with 0·75 mg/kg actinomycin *C* in saline solution (LD_{10}). Mice in the day 0 group were given actinomycin within 1 h after injection of sheep red cells. All the mice were bled by decapitation on day +9, sera being collected individually and titrated as previously reported[10]. Results are shown in Fig. 1.

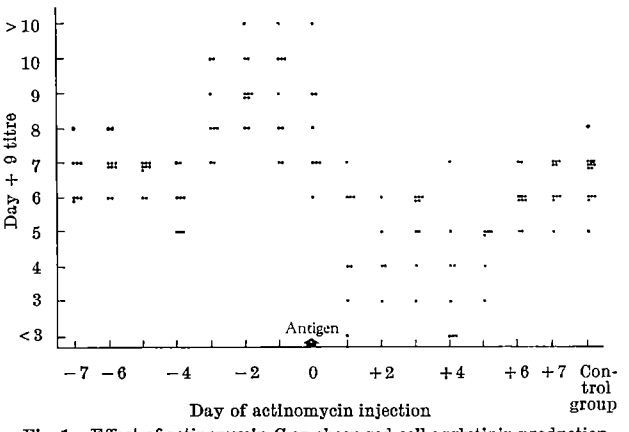

Fig. 1. Effect of actinomycin *C* on sheep red cell agglutinin production in *A2G* mice. Mice were injected with SRC antigen on day 0 and with actinomycin, 0·75 mg/kg, before or after injection of antigen. Sera were taken on day +9 and titrated individually. Titres are shown as reciprocals of the end-point dilutions, expressed as powers of the base 2

It is clear that actinomycin *C* has an action on antibody synthesis similar to that of antimetabolites and most alkylating agents, as it reduces the amount of antibody produced if given one to four days after the antigen[2,11]. It can be inferred that the period of maximal messenger RNA production is within these limits. Mice given actinomycin at a later stage of the primary response do not show significant suppression of antibody levels compared with untreated mice. Whether the observed reduction in titre on day +9 is temporary, that is, due to a lengthening of the induction period (cf. Wust *et al.*[5]), or permanent is being investigated.

Actinomycin given as a single dose in the 72-h period before injection of antigen enhances the antibody-level in mice bled on day +9. Similar effects have been observed with, for example, colchicine[12,14], colcemid[13] and 5-fluoro-2-deoxyuridine[15]. Rabbits given colchicine on days −1, 0 or +2, and sheep red cell antigen on day 0, had enhanced hæmolysin titres when bled during the next 3–4 weeks[12]. White[13] reported enhanced titres of antitoxin in guinea-pigs given colcemid 6 h before 5 *Lf* diphtheria toxoid. It has been suggested that colchicine may act by producing general cell damage, leading to release of metabolic products that aid in inducing the immune response and stimulate proliferation of antibody-producing cells[12,13]. Actinomycin, because of its action on messenger RNA, may divert a greater number of cells to the production of antibody against the antigen in question. The mechanism of this action cannot be really understood until the number of cells producing antibody are known.

Similar results have been obtained with another particulate antigen, T.A.B. vaccine, titrating the levels of *Salmonella typhi* H agglutinins in the serum. Experiments are in progress to compare soluble with particulate antigens.

The observed effects of actinomycin described here may be dependent on the dose-level used. Hirata and Redlich[14] found that hamsters given colchicine immediately after rabbit red-cell antigen had enhanced titres of antibody on day + 7 if non-toxic doses were used, but depressed titres with near lethal doses. This point needs further investigation.

I thank Farben Fabriken Bayer AG, Wuppertal-Elberfeld, for a gift of actinomycin *C*, and Dr. M. C. Berenbaum for his advice.

HISTOCHEMISTRY

Formazan Reaction as a Confirmatory Test for Aldehyde Groups in Histochemistry

One of us has predicted elsewhere[1] that not all neutral mucopolysaccharides can be demonstrated in tissue sections by the periodic acid–Schiff technique because the 'dialdehydes' which are formed by the periodate oxidation of their *vic*-glycol groups may be transformed into hemiacetals or hemialdals which are known to be unreactive towards Schiff's reagent *in vitro*[2]. On the other hand, all periodate-engendered 'dialdehydes' appear to react with aromatic hydrazines[2,3] including salicyloyl hydrazide and 2-hydroxy-3-naphthoic acid hydrazide[1]. Therefore, in tissues which have been treated with periodic acid, those mucin sites which take up hydrazine reagents but not Schiff's solution probably contain 'dialdehydes' in the hemialdal and/or hemiacetal forms. This hypothesis has now been confirmed by showing that the formazan reaction is negative in these sites.

Only aldehyde primary arylhydrazones (such as aldose phenylhydrazones) having a replaceable (acidic) α-hydrogen in their imino bond can be converted to coloured formazans by coupling with diazotized aromatic amines in an alcoholic or aqueous pyridine medium[4]. The phenylhydrazones of ketones[5] and 'dialdehydes' in the cyclic hemialdal form[2,6] cannot undergo this reaction.

The methods described in the literature[7–9] for carrying out the formazan reaction on tissue sections containing 'dialdehydes' engendered from neutral mucopolysaccharides or glycogen by periodic acid never worked in our hands. Pearse[8] has reported similar negative results with the 'mono' aldehydes produced in tissues by the acid hydrolysis of nuclear DNA, the hydrolysis of plasmal acetals, or the auto-oxidation of unsaturated lipids. We believe the failures are due to the extensive degradation of the aldehyde phenylhydrazones soon after their formation by the strong, hot solutions of phenylhydrazine acetate used in these methods. Such degradations have been established *in vitro*[10,11].

We have found the following technique to be reliable for differentiating aldehyde groups *in situ* from ketones and suspected hemialdals or hemiacetals. (1) Bring deparaffinized sections to water. (2) Immerse in a fresh 5 per cent solution of phenylhydrazine in 10 per cent acetic acid at room temperature for 3–5 min. (3) Wash briefly in 10 and 5 per cent solutions of acetic acid, followed by a final rinse in water. Blot the slide dry, and place on ice until the temperature of the section is approximately 0°–5°. (4) Put one drop of cold pyridine and one drop of a freshly prepared solution of diazotized aniline on top of the section, and leave for 3–5 min. (Diazotized aniline is prepared as follows: Dissolve 0·13 ml. aniline in 0·5 ml. water and 0·5 ml. hydrochloric acid, and cool to 0°. Add 0·1 g sodium nitrite dissolved in 1 ml. water slowly to the

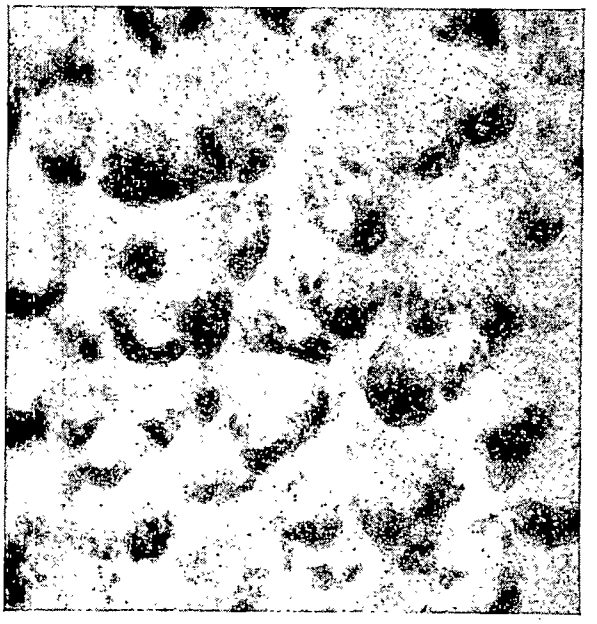

Fig. 1. Guinea-pig liver. 1 per cent periodic acid (*p*H 4·5) 8 min; uranium–formazan reaction (× 180). The 'glycogen flight' is evident

aniline mixture, keeping the temperature below 5°.) (5) Rinse in water. (6) Examine as a water mount. A light blue filter can be placed in the illuminating light path if the light yellow-brown formazans are difficult to see clearly. Photograph if required. (7) Remove the cover-slip and take the section through the alcohols to absolute alcohol. (8) Immerse in a warm (37°) 10 per cent solution of uranyl acetate in absolute ethanol for 10 min. (9) Take the sections down to water, wash successively in dilute (5 per cent) acetic acid and water, dehydrate to absolute alcohol, clear in xylene, and mount in 'Permount'.

Yellow-brown formazans can be observed in sites containing aldehydes after stage 6. Unfortunately, their contrast in sections mounted in 'Permount' is very poor. The orange-yellow uranium–formazan complexes formed after stage 9 are easily discernible.

The formazans formed from the 'dialdehydes' of periodate-oxidized glycogen in guinea-pig liver (fixed in ethylene glycol monomethyl ether acetate[12]) and of the neutral mucopolysaccharides in guinea-pig gut are shown in Figs. 1 and 2 respectively. In sites marked with an arrow in Fig. 2, formazans are absent. These sites in serial sections give strong reactions with hydrazide reagents but no reaction with Schiff's solution after oxidation in periodic acid. These sites probably contain 'dialdehydes' in the hemialdal form.

Fig. 2. Guinea-pig gut. 1 per cent periodic acid (*p*H 4·5) 8 min; uranium-formazan reaction (× 240). The formazan reaction is positive in the superficial goblet cells, whereas in the deep crypts of Lieberkühn it is negligible or absent

The amount of formazan ultimately formed from periodate-oxidized polysaccharides is maximal when the sections are immersed in the phenylhydrazine solution for 3–5 min. After immersion for about 7–8 min, the capacity for formazan formation decreases and is zero after 15–20 min. Why this should happen is still undetermined. Possibly the 'dialdehyde' phenylhydrazones are transformed to hemiacetal or hemialdal derivatives, or alternatively[13] to benzeneazoalkane derivatives.

Neither 'stabilized' diazonium salts nor freshly diazotized amines other than aniline, such as sulphanilic acid[14], *p*-amino-*N*,*N*-dimethylaniline, or morphilino-2 : 5-diethoxyaniline, would couple with aldehyde phenylhydrazones *in situ*, contrary to their ability to do so *in vitro*.

The ability of formazans to form highly coloured complexes with metals[15] has been utilized to improve the contrast of formazans *in situ*. The appearance of these complexes in the electron microscope is now being examined.

RADIOBIOLOGY

Distribution and Excretion of Dentifrice Fluoride

The inclusion of 1 mg of fluoride per g of paste in a stannous fluoride dentifrice has led to the suggestion that chronic fluoride poisoning could arise during the prolonged use of such a preparation. Although it can be calculated that systemic fluorosis will not follow even the most abnormal use of a stannous fluoride paste this conclusion is, as yet, supported by only scanty experimental evidence.

To estimate the amount of fluoride retained in the body after the use of a sodium fluoride dentifrice[1] and various simplified fluoride dentifrices[2], the fluoride recovered from the toothbrush and rinsing water has been determined chemically[1] and by the use of radioactive fluorine[3]. In addition, urine excretion of fluoride has been estimated in children[3,4] and in adults[5] who were using a commercially available fluoride dentifrice, but data on the ingestion and excretion of fluoride after using a single brushful of a proprietary stannous fluoride dentifrice are lacking. This information has been obtained in the following experiment.

Immediately after emptying the bladder, ten male subjects, ranging in age from 23 to 33 years, brushed their teeth with a weighed quantity of a stannous fluoride dentifrice ('Crest', Procter and Gamble Co.) labelled with 1–2 μc. ^{18}F at the time of use. After brushing for 1 min the mouth was rinsed with 25 ml. tap water. The unwashed brush and the rinsings were retained for radioactivity counting. Urine samples were collected at hourly intervals over a 4-h period. The subjects ate a sandwich lunch immediately after collection of the first urine sample. Their fluid intake was limited to avoid excessive dilution of ^{18}F in the urine which might have led to counting inaccuracies. The residual paste was washed from the used toothbrushes, and duplicate 5-ml. samples of the suspended washings were counted in a well-type scintillation counter. Aliquots of the expectorated rinsings, and hourly urine samples, were similarly counted. Standards were prepared from weighed quantities of ^{18}F-labelled dentifrice.

The results (Table 1) show that a mean of 25 per cent of the fluoride, measured as radioactive fluoride, was recovered from the 10 unwashed brushes after each had

been used for 1 min. 51 per cent of the fluoride was found in the water used for rinsing the mouth. Thus the mean total recovery of fluoride from 10 subjects was 76 per cent—a percentage recovery similar to that reported for a sodium fluoride dentifrice[1]. If slight losses on the lips, which could not be measured, are ignored, 24 per cent of the fluoride must have remained in the mouth or have been swallowed. Some of this retained fluoride was absorbed because 1·3 per cent of the ^{18}F was excreted in the urine in the 4 h following brushing. The short half-life of ^{18}F made it impracticable to follow the excretion longer.

Table 1. Percentage Distribution of ^{18}F after Toothbrushing (10 Subjects)

	Range	Mean	S.D.
Recovered on brush	12·1–45·4	24·8	±10·9
Recovered in mouthwash	33·6–66·0	50·9	±14·1
Total recovered	51·7–86·4	75·7	± 9·5
Retained	13·6–48·3	24·3	±10·0
Excreted in urine	0·12– 5·3	1·3	± 1·4

Before drawing conclusions from excretion of ^{18}F in urine collected for only 4 h it must be stated that its rapid absorption and urinary excretion have been demonstrated in human subjects[6]. In these experiments with toothpaste more fluoride would have been excreted in a longer time, but because the rate of excretion of ^{18}F was falling the percentage increment would have been small. Therefore, this 4-h examination underestimates the excretion of a single dose of dentifrice fluoride, but nevertheless provides a reasonably accurate measurement.

The distribution within the body of the 24 per cent fluorine-18 which was not recovered from the brush or the mouthwash is incompletely known. From data on the *in vivo* uptake of ^{18}F from labelled dentifrice[7], it can be calculated that the enamel of a full complement of teeth will retain less than 1 per cent of the fluoride, leaving at least 23 per cent to be swallowed. Direct measurement of the absorption of ^{18}F, and fæcal estimation of unabsorbed fluoride, are impracticable with this radioisotope, but it has been shown that when additional fluoride is given to subjects for short periods half the fluoride absorbed is excreted in the urine[8]. Therefore, it seems that the subjects in this toothbrushing experiment absorbed about 3 per cent of the fluoride originally present on the toothbrush. Between 0·5 and 1·0 g of paste, containing, according to the manufacturer, 1·0 mg of fluoride per g, was used. Therefore, 15–30 μg of fluoride was absorbed by the subjects but half of it had been excreted 4 h after brushing the teeth. This amount is only 5–10 per cent of the daily physiological variation in urinary fluoride excretion, so that it is not surprising that earlier workers[3–5] failed to detect an increased fluoride excretion in subjects using a stannous fluoride dentifrice. The toothpaste would have had to be used very many times a day to produce a significant increase in the fluoride excreted in the urine.

The very small contribution to fluoride storage made by this stannous fluoride dentifrice indicates that under the conditions described here this preparation will not cause chronic fluoride poisoning.

Zinc-65 in Human Hair

In 1963, we reported that the hair of rats injected with strontium-90 retained a significant amount of the radionuclide, and suggested that measurement of the radioactivity of the hair might furnish a non-destructive method of estimating the bone content, or body burden, of the radioisotope[1]. This concept has been confirmed recently by Della Rosa *et al.*[2] in work on the strontium-90 content of beagle hair during and following the chronic ingestion of the radioelement.

We are now collecting information on the accumulation of radionuclides in human hair and have begun with investigations on zinc-65. This is a logical progression, since it has been known for some time that radiozinc accumulates in rat hair[3–5], chicken feathers[6], and fish scales[7]. Zinc-65 is a potential health hazard through its formation in fall-out and nuclear reactions as proved by its occurrence in public waters[8,9]; in meat[10], milk[11], seafood[7,12], and vegetables[9]; in cyclotron[13] and reactor[14] workers; and its increasing level in the body burden of the Rongelap Islanders[15].

The radiozinc determinations were carried out as part of an investigation of the zinc content of head hair obtained from male Egyptian dwarfs suffering from zinc deficiency and presenting with the syndrome of iron deficiency anæmia, hepatosplenomegaly and hypogonadism[16,17]. Hair from the nape of the neck was obtained from each of six dwarfs who had been injected intravenously with 36–80 μc. of zinc-65 chloride some months prior to the sampling and were receiving oral medication with zinc sulphate. One-gram samples of hair were washed with a detergent, dried, and counted in a well counter with an efficiency of about 28 per cent. The data showing time in months after injection, dose of zinc-65, and hair radioactivity are given in Table 1. As is evident, the radioactivity of the hair was low in samples taken after 19 months but relatively high in the single sample of hair taken after six months from dwarf 6. There does not seem to be a direct relationship between the radiozinc dose and hair-level in dwarfs 1–5. This variation may be due in part to differences in level of medication with zinc sulphate over the 19–22 months of observation. The radioactivity of the hair from the dwarfs does not compare with the high values measured in rat hair, where this appendage may become the most radioactive part of the body with continued ingestion of zinc-65.

Table 1. Radioactivity of Hair from Egyptian Dwarfs injected with Zinc-65

Dwarf	Months after injection	Zinc-65 dose (μc.)	Hair radioactivity (c.p.m./g)
1	22	80	62
2	21	50	85
3	21	60	0
4	20	36	72
5	19	60	0
6	7	65	678

The determination of the level of radioactivity in the hair, together with the identification of the radionuclide present, may become a very useful tool in radioecology whenever long-lived radioisotopes are being investigated. Measurements already published show that iodine-131 (ref. 18), selenium-75 (ref. 19), sulphur-35 (ref. 20), and vanadium-48 (ref. 21), as well as strontium-90 (ref. 22) and zinc-65, accumulate in the hair of laboratory animals. We also have unpublished observations which show that calcium-47, chromium-51, cobalt-58, and iron-59 are retained by rat hair. Further observations on man are needed to establish that these observations on animals apply equally well to human beings.

We thank Dr. A. R. Schulert, NAMRU-3, Cairo, Egypt, for the hair specimens from the dwarfs.

BIOLOGY

Sex Ratios in Marsupial Pouch Young

ALTHOUGH sex ratios favouring males at birth are well known in eutherian mammals[1,2], we do not know of any published data showing a disparity between males and females in marsupial pouch young beyond the 0·25 level of probability.

A sample of 420 pouch young of the macropod *Macropus canguru* and 410 of *Macropus rufus* was collected in south-west Queensland, Australia. Pouch young with pes measuring less than 8 mm were excluded from both samples because the scrotum is not clearly defined in smaller animals. Pouch-young sex ratios of the phalanger *Trichosurus vulpecula* were recorded in New Zealand between 1953 and 1961, the same criteria being used for sexing and animals weighing less than 1·7 g being rejected. A standard χ^2 test ($\chi^2 = 6{\cdot}06$) indicates that the assumption of a constant sex ratio for the nine yearly samples can be accepted; the samples were therefore pooled, giving a total of 626 pouch young.

None of these three samples provides evidence of differential mortality during life in the pouch. Sex ratios of the macropod pouch young with pes measuring more than 140 mm do not differ significantly from those of young with smaller pes ($\chi^2 = 0{\cdot}05$ for *M. canguru*; 1·36 for *M. rufus*). This also applies to the pouch young of *Trichosurus vulpecula* below and above 53 g in weight ($\chi^2 = 0{\cdot}47$).

The sample of *M. canguru* pouch young comprised 242 males and 178 females, a ratio, with 95 per cent confidence limits, of $(136 \pm 26)\ M/100F$. Approximate confidence limits were assigned by the formula[3]:

$$\frac{100\,M}{F} \pm \left(100\sqrt{\frac{(M+F)\,M}{F^3}}\right)1{\cdot}96$$

There is less than one chance in 500 that the disparity is due to sampling variation. As there is no evidence of differential mortality we assume that there is a disparity at birth.

* Figures in this column are χ^2 values for a disparity between males and females.

† P = probability of drawing a more extreme sample from a population with a sex ratio of 1 : 1.

The published figures for *Trichosurus vulpecula* and those presented here can be assumed to come from populations with a common sex ratio ($\chi^2 = 1{\cdot}10$; d.f. = 3), and all were therefore pooled, giving $(114 \pm 15)M/100F$. calculated from a total of 908 pouch young. The disparity is probable at the 0·1–0·05 level. Each of the four sex ratios favours males (Table 1). This suggests that the disparity may be real despite the non-significant χ^2 value, but about 750 more determinations would be needed for a 0·01 probability if the ratio were, in fact, $114M/100F$.

Pouch-young sex ratios of other marsupial species are listed in Table 1. In no case do they clearly indicate a dominance of males in the populations from which they were drawn. Only *Macropus canguru* shows a disparity at birth, but further data might possibly establish an excess of males in *Trichosurus vulpecula*.

The figures for the two species of *Macropus* were collected while the first author was at the School of Biological Sciences, University of Sydney. We thank Mr. C. L. Batcheler and Dr. W. G. Warren for advice.

Molluscicidal Activity of Surface-active Agents on the Snail *Biomphalaria sudanica*; a Vector of Bilharzia

PREVIOUS work on a naturally occurring substance which inhibits growth in *Biomphalaria sudanica*[1] indicated that its toxicity was partly due to its surface activity. It was therefore decided to test various commercially produced surface-active agents, at various concentrations, on the survival of this species of snail.

As the result of requests to British manufacturers of surface-active agents for samples of their products, we obtained more than 100 compounds, which were dissolved at 5 different concentrations, ranging from 0·1 to 1,000 p.p.m., in an artificial medium containing the major inorganic ions found in Lake Victoria, in the concentrations in which they occur in the lake.

The surface tension of these solutions was determined at 30° C by means of the drop-weight method of Harkins and Brown[2], and the apparatus used was virtually identical with that described by Harkins and Alexander[3].

For the 101 detergents tested it was found that 5 were non-toxic to the snails, even at concentrations of 1,000 p.p.m., that 22 were toxic at 1,000 p.p.m., 39 at 100 p.p.m., 23 at 10 p.p.m., 10 at 1 p.p.m., and, finally, 2 were found to kill the snails at a concentration as low as 0·1 p.p.m. Death of the snail was sometimes obviously due to hæmolysis, but this effect did not occur each time, and the amount of hæmolysis was certainly unrelated to the toxicity of the surface-active components.

The substances which killed the snails at the lowest concentration so far investigated (0·1 p.p.m.) were the tertiary amines 'Empigen *AE*3' and 'Empigen *AN*' (the surface tensions measured at this concentration were respectively 71 and 65 dynes cm^{-1}).

No direct correlation could be detected between the surface activity of the detergents and their toxicity on *Biomphalaria*. 'Ethylan *PC*', for example, had a surface tension of approximately 37 dynes cm^{-1} at a concentration of 1,000 p.p.m., but this proved, at this concentration, to be non-toxic to the snail. On the other hand, the most surface-active substance tested so far, 'Deciquam 222' (which at a concentration of 1,000 p.p.m. gave a surface tension of approximately 13 dynes cm^{-1}), killed the snail at a concentration of 1 p.p.m. and a surface tension of 69 dynes cm^{-1}.

It was found that the cationic detergents were, on the whole, more toxic than the anionic or non-ionic ones.

Mixtures of anionic and cationic agents were found, on the whole, to be less toxic then the surface-active agents separately. Thus, a mixture containing 100 p.p.m. 'Perlankrol *TL*' and 100 p.p.m. 'Cibaphasol *C*' did not kill snails even after 89 h whereas the separate components, at the same concentration, killed them after 20 and 5 h respectively. The addition of 'Silicone *MS* antifoam *A*' (Hopkin and Williams) to the surface-active agents lowered the toxic concentration in most cases by a factor of 10–100. The influence of the silicone was particularly evident in the case of the anionic and cationic agents. From these experiments it can be concluded that the toxic effect of most surface-active agents on *Biomphalaria* has both a chemical and a physical origin.

It was found that the eggs of *Biomphalaria sudanica* were more resistant to the surface-active compounds than was the snail itself. While the snails were killed within 1 h in certain detergents at a concentration of 1,000 p.p.m., most of the embryos in the eggs survived this concentration for more than 24 h. Concentrations of 10 p.p.m. and less of any of the surface-active agents investigated had no detectable harmful effect on the embryos.

These findings may be useful in the selection of surface-active agents which, apart from their own molluscicidal activity, can also be used for the dispersion of almost insoluble molluscicides.

Some Biological and Biochemical Properties of the Polarizing Factor in *Hydra*

TRIPP[1] proposed a growth pattern for *Hydra* which was later confirmed by Brien[2] and Burnett and Garofalo[3]. Beneath the hypostome of *Hydra* a growth region exists where cell proliferations constantly occur. Cell divisions in this area force adjacent cells distally to the tentacle tips and proximally to the basal disk. When cells reach the extremity of the body column they die and are sloughed off. Thus, the animal is capable of continual growth without a change in form.

Burnett[4] postulated the existence of a growth-stimulating principle which controls cell division and ultimately head formation along the length of the body column. According to this hypothesis, the growth-stimulating material is concentrated in the hypostome. It diffuses proximally from this location in a gradient until it reaches the basal disk. The reason that heads fail to form along the entire column is because of the presence of a postulated inhibitor, produced in the sub-hypostomal growth region which also diffuses proximally. This inhibitor specifically blocks the action of the stimulator and the ratio of stimulator to inhibitor in any body region determines the form of that region. For example, in the budding region the inhibitor is dilute and the residual stimulator in this region induces cell divisions necessary for the elaboration of a new polyp. If the growth pattern in *Hydra* is chemically controlled as hypothesized, it should be possible to define quantitatively the mode of action of these agents and to purify them.

This communication reports preliminary investigation into the chemical and biological nature of the growth stimulatory material only. We have isolated a substance from *Hydra* capable of inverting polarity. The material is obtained from homogenates of *Hydra* boiled 10 min to stimulate nematocyst discharge. (Nematocyst toxin is lethal to the *Hydra* after its release from the capsule.) The active factor is located in the supernatant of a fraction sedimented after centrifuging the homogenate at 25,000*g* for 50 min. Annuli of tissue excised from the gastric-budding region junction of *Hydra pirardi* when exposed to these extracts for 4 h exhibit subsequent excessive tentacle or head growth during regeneration. Inverted polarity develops in more than 20 per cent (0·222) of the surviving animals as opposed to spontaneous production of supernumerary tentacles in less than 2 per cent (0·016) of 387 control animals tested (that is, annuli allowed to regenerate in culture solution without prior incubation in an extract containing growth-stimulating principle). No control animal ever developed an excessive number of tentacles, only their placement along the body column was abnormal, and here never more than two tentacles were located outside the oral ring.

Growth-stimulating material is concentrated in the distal portion of normal animals (Table 1). The activity of this area approximates that of whole animal extracts. Although the mechanism of action of the extracted material is unknown, it probably enters the assay animal by diffusion during the incubation period. Evidence for this conjecture is, first, the material can be collected in agar blocks and can be introduced afterwards from the

Table 1. Biological and Biochemical Properties of Hydra Growth-stimulatory Material

agar into a test animal, and, secondly, exposure of annuli to fresh extract between 4 and 8 h of regeneration results in 50 per cent less abnormal growth than if exposure to the extract occurs during the first 4 h after cutting. Wound healing is effectively completed after 6 h and an epidermal mucous film, resistant to the penetration of most exogenous free materials, is intact.

Preliminary examination of the extract with the electron microscope indicates the presence of a particulate material (900 Å). This material is not species specific, for it has been isolated from *H. viridis* as well as *H. pirardi*.

Animals in physiological depression (tentacles clubbed, inability to feed) possess only minute quantities of the active material (Table 1). *Hydra* exposed to nitrogen mustard, which specifically eliminated interstitial cells from the animals, also show only trace amounts of the material (Table 1). Also, it has been demonstrated that during sexuality growth in *H. pirardi* ceases[4]. It will be seen in Table 1 that after 4 weeks at reduced temperatures (the stimulus-inducing sexuality in this species) activity falls to nearly one-half that of normal animals. After 8 weeks at reduced temperatures activity is lacking entirely. Extracts of animals treated with leucomethylene blue to eliminate the nervous system result in a 50 per cent decrease in the number of animals developing inverted polarity.

Initial biochemical characterization of the growth-stimulating principle (Table 1) reveals that the material is relatively heat stable, not extractable with lipid solvents, digested by proteolytic enzymes, and slowly dialysable. Its action is not significantly mimicked by inhibitors of carbohydrate metabolism, for example, sodium fluoride, oxidative inhibitors such as potassium cyanide and lithium chloride, or by neurogenic compounds such as acetylcholine or noradrenaline. Preliminary purification with *G25* grade 'Sephadex' shows the active material to be retained on the column for an extended period.

It should be stressed that the ability of growth material isolated from the peduncle and basal disk to produce excessive head development is only half that of material extracted from the hypostomal region (Table 1). This further substantiates the idea that the stimulator extends in a gradient along the body column.

We suggest that the growth-stimulating principle is responsible for polarity in the *Hydra*. Whenever a portion of the body column is transected and an annulus removed, a head always forms on the original distal cut surface and a base on the proximal. If the growth factor extends in a gradient from the head to the base, then growth activities would be maximal at the distal cut surface. Cell divisions here would then liberate an inhibitor suppressing growth activities at the proximal surface.

At present, the chemical nature of the stimulator is not known. The present biochemical analysis suggests that the active factor may be a peptide.

Rotting of Apples of the Variety 'Bramley's Seedling' by *Nectria galligena*, Bres.

The first records of fruit rotting by *N. galligena* were made by Salmon and Wormald in Kent[1] and Dillon-Weston in the Wisbech area[2], where it occurred on the variety 'Worcester Pearmain'; it has since been reported as troublesome on a number of dessert varieties in various European countries[3–6]. Typical infection occurs at the blossom end of the fruit, either through the open calyx[7] or lenticels[8], and the disease became known as eye rot[1]. The rot frequently develops while the fruit is still on the tree[2], and the cream-coloured conidial masses of the imperfect stage, *Cylindrocarpon mali* (Allesch.) Wr., appear on the surface[1,2]. Such fruit, if left on the tree, become mummified, and perithecia are formed during the winter following infection[2].

Hitherto, fruit rotting by this organism of the variety 'Bramley's Seedling' has not been reported, although the wood-canker phase is widespread. *N. galligena* was identified as the causal organism of a number of rotted apples of 'Bramley's Seedling' held in gas and barn store in Co. Armagh during 1961–62 and 1962–63. Approximately 20 per cent of the fruit from one particular orchard, held in gas storage until May 1963, was found to have rotted, and more than half this loss was attributable to *N. galligena*. Wood cankers were particularly abundant in this heavily manured orchard.

During the storage period of 1963–64 samples of rotted apples, taken from various stores in Northern Ireland, were examined and the causal organism, if any, isolated. A total of 395 isolations were made and the percentages of this total attributable to the following principal organisms found were: *N. galligena*, 30 per cent; *Penicillium expansum*, 21 per cent; *Gloeosporium* spp., 13 per cent; *Phomopsis mali*, 10 per cent. *N. galligena* was by far the most serious cause of loss, particularly in the late storage period.

Most of the rots produced by *N. galligena* on 'Bramley's Seedling' fruit developed at the stalk end. The rotted area had a somewhat sunken appearance, was dark brown in colour with a distinct margin between the healthy and rotted areas (Fig. 1). Conidial masses were sometimes found on the surface. Internally the rotted tissue was soft and moist, light brown in colour, and frequently had a somewhat grained appearance, the striations running parallel with the line of radial advance. Microscopic

Fig. 1. Natural rot of Bramley's Seedling apple caused by *Nectria galligena*, viewed from the stalk end

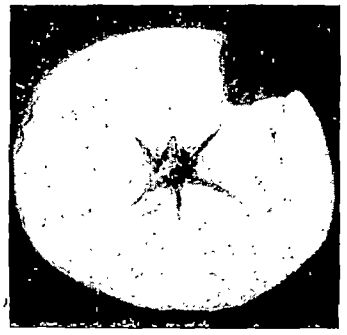

Fig. 2. Section through an unripe apple artificially inoculated with *Nectria galligena*, showing the arrested development of the rot

examination showed that the hyphæ advanced intercellularly and that eventually the host cells were completely disintegrated. Naturally infected fruit, partially buried in moist peat, and left exposed outside during the winter, developed perithecia with mature asci in about three months.

Artificial inoculation using the cork borer method[9] indicated that the fruit at harvest time showed an unexpected form of resistance to invasion by the fungus. During the first 20 days of incubation at 20° C the rot in all fruit reached an external diameter of 15–20 mm; but its further development was arrested and a distinct ridge developed at the edge as the rotted tissue shrank (Fig. 2). Internally the rot was firm and relatively dry; it was bordered by a layer six to seven cells thick with dense brown granular contents (Fig. 2). In many cases it recommenced in an erratic manner after incubation for 35–40 days; but in approximately a quarter of the fruit no further rotting took place and attempts to re-isolate the fungus from them failed, presumably because the hyphæ were dead. It can only be assumed that during the development of the rot in unripe fruit some chemical substance is elaborated which is highly toxic to the fungus. Similar inoculation of riper fruit did not show this phenomenon and the rot developed unhindered; it was similar in appearance to that described for naturally infected apples and the fungus was readily re-isolated.

Fine Structure of Tyloses

Microchemical methods have shown that in several species, tylosis walls consist of more than one layer[1]. The outer layer is covered by an amorphous granular material while the inner surface has a crossed microfibrillar structure[2]. In the present investigation of *Eucalyptus obliqua* L'Herit. and *E. miniata* A. Cunn. ex Schau., it was found that at least a part of the granular material is derived from the denatured contents of the vessel, and that on extraction in 2 per cent sodium hydroxide the surface could be seen to have randomly arranged microfibrils, as in a primary wall. Ultra-thin sections of budding tyloses showed that, even in the early stages of development, their walls consisted of two layers. There was an outer layer, which appeared amorphous in sections, and an inner multi-lamellate layer with, at least in the more mature tyloses, very regular alternation of the direction of the microfibrils in adjacent lamellæ. This was particularly obvious in the sclerosed tyloses of *E. miniata* where the multi-lamellate layer contributed largely to the thickened wall. The structure of the inner layer, therefore, was quite unlike that of the secondary wall of the ray cell from which it arose, and resembled more that of some green algae such as *Valonia*[3].

In *E. obliqua* the walls of the fully developed tyloses were of the same thickness as those in the initial stages of growth, so that wall deposition must accompany wall extension. In some cases, even where the tylosis had not yet bulged out into the lumen of the vessel, its wall was almost as thick as the secondary wall of the ray cell.

Particular interest, however, attaches to the origin of the tylosis wall. In sections through the base of tyloses in *E. obliqua* (Fig. 1) it could be seen that the tylosis wall is continuous with neither the primary nor the secondary walls of the ray cell, but with a distinct layer (arrowed Fig. 1) lining the inner surface of the ray cell secondary wall. This layer was particularly well developed on the wall adjacent to the vessel and was quite different in texture from the secondary walls of either the ray cell or the vessel. In the initial stages of development, the tylosis wall formed a separate layer lining the pit membrane, but, as the tyloses developed, the pit membranes

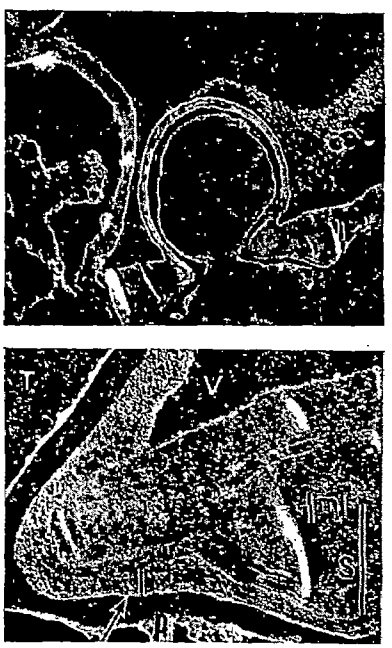

Fig. 1. Above, electron micrograph of ultra-thin section of budding tyloses of *E. obliqua*. (× *c.* 1,330). Below, detail of tylosis base (× *c.* 5,660). *ml*, Middle lamella + primary walls; *S*, secondary wall of the ray cell; *V* lumen of vessel; *P*, lumen of ray cell; *T*, lumen of tylosis

ost their separate identity, except perhaps at the bases of the tyloses. It would appear that the tylosis-forming ayer originated beneath the pits, as it was commonly hickest in these regions, and spread over the adjacent ayers of the secondary wall, in the same way that the ndividual layers of the secondary wall extend progressively from the central regions to the tips of the fibres[4].

The organization and origin of the tylosis wall indicate that this is in some ways a unique structure. The outer layer has the organization of a primary wall, and in view of the fact that the multi-lamellate layer is well developed even in immature tyloses, the tylosis wall is perhaps better regarded as a thick primary wall rather than a secondary wall. This means that the ray cell, having synthesized a secondary wall at the time of the initial differentiation of the cell, reverts to synthesizing a primary structure during tylosis production. Such reversion from a crossed fibrillar structure to a more random arrangement of the microfibrils has also been observed in some green algae following plasmolysis of the cell[5].

Investigations are continuing into the cytoplasmic organization of tyloses with particular reference to the behaviour of the nucleus.

Factors affecting the Emergence of Primary Tillers from the True Leaves of the Main Shoot of a Rice Plant

Katayama[1], in his investigation of tillering in some cereals, reported that in the main culm and its tillers, the initiation of tillers and the development of leaves proceeded successively, maintaining a definite regularity and interval.

I have found (unpublished observations) that the first and second primary tiller of a swamp rice plant (variety *BG* 79) together contribute more than 50 per cent of the total shoot number of a plant, regardless of the fertility of the soil and plant population density.

Various factors affect the production of shoots in rice plants. It has been shown, for example, that tillering is affected by soil moisture[2–4] and by soil fertility[5–8].

The first relationship investigated was that between the leaf stage of the seedlings at the time of transplanting, and the emergence of the primary tillers from the first true leaves. This is affected by the moisture of the soil to which the seedlings are transplanted. Seedlings were transplanted to soil in pots at their first-, second- and third-leaf stages. The soil in half of the pots for each leaf-stage group was flooded (3 cm standing water) and the soil in the others was maintained at 80 per cent saturation. Tiller number was counted at the sixth-leaf stage (Table 1).

Flooding depressed the appearance of the primary tiller and the number produced fell when the seedlings were transplanted at a later leaf-stage. There was a significant difference between the effect of flooded and 'dry' soil when the seedlings were transplanted at the first- and second-leaf stages. This is shown by the analysis of the interaction.

The second factor investigated was the effect of time of commencement of flooding on the emergence of the primary tiller from the first true leaves.

The seedlings were raised in plastic buckets each containing six plants. Seedlings in half the buckets were uprooted and then replanted at the first-leaf stage. The soil in one-third of the buckets containing replanted and undisturbed seedlings was flooded at the first-, second- and third-leaf stages. Tillers were counted at the sixth-leaf stage of the main shoot and the results are shown in Table 2.

Table 1. Effect of Leaf Stage and Soil Moisture at the Time of Transplanting on the Emergence of the Primary Tiller from the First True Leaves

	'Dry' soil	Flooded soil	Leaf stages First	Second	Third
Total tiller per treatment	30*	5	20*	13*	2
F value		15·9*		6·4*	
L.S.D. ($P = 0·05$)		4·97		4·07	

Interaction (leaf stage × soil moisture saturation)

	Leaf stages First	Second	Third
'Dry' soil (*D*)	15	13	2
Flooded soil (*F*)	5	0	0
(*D*–*F*)	+10†	+13†	+2

L.S.D. ($P = 0·05$) = 4·07

* Significant ($P = 0·01$).
† Significant ($P = 0·05$).

Table 2. Effect of Replanting and of Leaf Stage at the Time of Flooding on the Appearance of the Primary Tiller from the First True Leaves

	Replanted seedlings	Non-replanted seedlings	*L.S.D.* $P = 0·05$	Leaf stages First	Second	Third	*L.S.D.* $P = 0·05$
Total tiller per bucket	2·25	5·0*	1·5	4·50*	2·25	4·13*	1·8
F value			16·0*		4·2*		

Interactions (replanting × leaf stage at time of flooding)

	Leaf stages First	Second	Third
Replanted (*R*)	3·25	1·25	2·25
Non-replanted (*NR*)	5·75	3·25	6·00
(*NR*—*R*)	+2·5†	+2·0	+3·75†

L.S.D. ($P = 0·05$) = 2·5

* Significant ($P = 0·01$).
† Significant ($P = 0·05$).

Seedlings that were not replanted produced significantly more tillers than the replanted ones. Seedlings growing on soil flooded as from the first- and third-leaf stages produced more tillers than those growing on soil flooded as from the second-leaf stage, irrespective of whether the seedlings were replanted or not.

It appeared that the seedlings received a setback at the time of transplanting and that it was less severe when they were transplanted at the first- or second-leaf stages than at the third. The effect was more strongly adverse when the seedlings were transplanted to anaerobic than to aerobic soil ('dry' soil). The roots of the rice seedlings were probably not adapted to anaerobic conditions, especially when they were raised on aerobic soil in the nursery. The sudden transfer to anaerobic soil probably prevented the growth of the primary tiller from the first true leaves. Unpublished results have shown that this tiller emerges at the fourth-leaf stage of the main shoot. It probably started its growth at the second-leaf stage of the main shoot, so that a change in the soil environment at this stage would have the most adverse effect on its emergence.

The third factor investigated was the effect of the presence of subtending leaf lamina and sheath on the emergence of primary tillers from the first and second true leaves. The seedlings were raised in pots each containing six plants. The treatments applied to the first and second leaves of the seedlings were (*a*) leaf lamina not removed, (*b*) half-leaf lamina removed, (*c*) whole leaf lamina removed, (*d*) leaf lamina and sheath removed (the organs were removed with scissors). The appearance of the tillers was observed at the seventh-leaf stage. The total numbers of tillers produced for treatments (*a*), (*b*), (*c*) and (*d*) were 23, 27, 10 and 22 respectively. The least significant difference ($P = 0·05$) was 8.

The removal of the leaf sheath probably exposed the bud in its axil to light and this probably stimulated its growth. When the leaf lamina was intact it appeared to have received and conveyed the light stimulus to its axillary bud, and this was then stimulated to grow. This influence of leaf lamina on bud growth may account for the usual

lack of tiller development from the axils of the coleoptiles of a rice plant.

Observation made on plants grown in pots showed that the leaf stage of the main shoot is also a factor governing tiller emergence from the main shoot. Table 3 shows the leaf stage of the main shoot at the time of emergence of each primary tiller.

Table 3. Leaf Stage of the Main Shoot at the Time of Appearance of each Primary Tiller

Primary tiller	1	2	3	4	5	6
Leaf stages	½ fourth	fifth	½ sixth	½ seventh	½ eighth	½ ninth
Primary tiller	7	8	9	10	11	
Leaf stages	½ tenth	½ eleventh	½ twelfth	½ thirteenth	fourteenth	

Fractions indicate the unfolded portion of the leaf blade.

It was also observed that before the appearance of a new tiller on the main shoot the preceding one was always in its second-leaf stage. The leaves developing early on the main shoot were usually smaller than those which developed later. The latter, therefore, took longer to unfold. Also, the second leaf of each primary tiller increased in size as the tillering process progressed upwards along the axis of the main shoot. The time taken for the second leaf to unfold was, therefore, progressively prolonged as the tillering process progressed upwards along the main stem. The differences in the unfolding period of the leaves, it is suggested, might be partly responsible for the increased interval between the appearance of a new primary tiller and a preceding one as shown in Fig. 1.

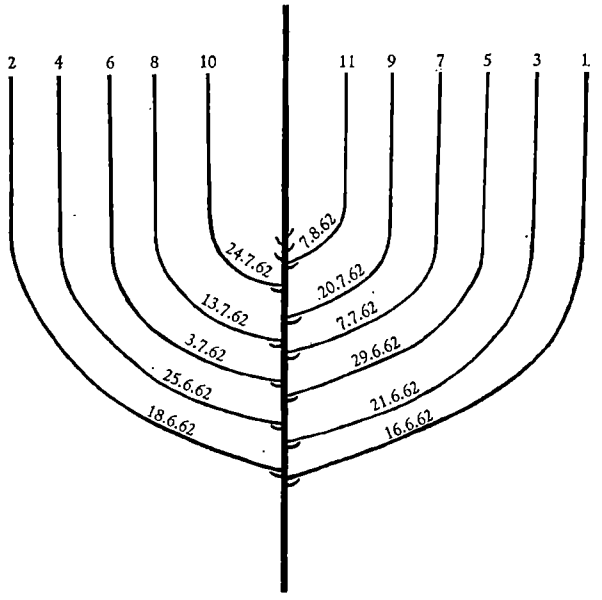

Fig. 1. Diagrammatic representation of a rice plant showing the mode of primary tiller development and the dates of emergence from the leaf sheaths of the subtending leaves on the main shoot

Where light and plant nutrients are not lacking it is possible to identify fairly accurately, from the leaf stage of the main shoot, the last tiller that has emerged from the main shoot during the tillering period. However, at low light intensity and in poor soil conditions, the development of primary tillers on the upper nodes of the main stem will be inhibited and under these conditions one cannot identify the last-formed tiller merely by knowing the leaf stage of the main stem. In a nursery where rice seedlings are overcrowded the competition for light and nutrients may inhibit the development of the primary tillers from the first-formed leaves of the main stem. According to the data shown in Table 1, if such seedlings are transplanted to the field at the sixth-leaf stage, only the primary tillers from the fourth leaf upwards are very likely to be produced. This will result in a reduction in the yield of the crop, especially if the plants are widely spaced, for I have, as stated, data showing that the primary tillers from the first and second true leaves together contribute more than 50 per cent of the yield of a rice plant.

Leaf Spiral and Yield in Coconuts

This communication refers to the recent article by Satyabalan, Ninan and Krishna Marar[1], who perhaps unconsciously give more publicity to my findings relating to foliar asymmetry in the coconut palm[2–4]. The very first line of their statement, referring to the work of Petch[5], is misleading. Petch did not deal with leaf-spirals of coconut in his paper and, in fact, there is no mention of leaf or foliar-spiral, or the arrangement of leaves along five spirals in a clockwise or anti-clockwise direction as reported. Presumably Petch's article was not available to the above authors. Petch explained the structure of the fibres in the coconut stem. Neglecting the outer rind, he found in a stem the vascular bundles sloping to the left in the outer 3·5 cm, followed by an abrupt reversal of direction for the next 3·5 cm. This was again followed by another reversal to the original left in the remaining inner core of the stem. In another stem, the condition was reversed; the same three regions were present, but in the outer the bundles sloped up to the right, in the intermediate to the left, and in the inner to the right again. These two types of palms were regarded by Petch as right- and left-handed coconut trees.

Quotations from, and reference to, my work cover about a third of Satyabalan and others' communication. But if they had given due importance to the following sentence of my paper given within brackets ("My yield data relate to a small locality in Kerala and I do not claim that this will be the situation elsewhere."), much of their criticism could have been spared. My figures on the nut-production were from Kayangulam, a small town in central Kerala. In one part of their communication, the foregoing authors isolate this locality as "a place affected by a devastating virus disease of coconuts", but later on claim that Kayangulam and Kasaragod (extreme north-west of Kerala, about 500 km away from Kayangulam) have the same variety of palms "growing under almost identical climatic and soil conditions".

I am trying to obtain from India and abroad yield data on the two types of coconuts as well as other plants which show asymmetry of the stem, leaves or flowers. Through the kindness of Dr. M. N. Sproat, director of agriculture, Trust Territory of the Pacific Islands, kernel yields from 100 left-handed and an equal number of right-handed coconut palms on Ponape Island for the year 1963 were weighed. The left–right difference of kernel yield is quite high, being 13·48 per cent (that is, 31·24–27·53 lb. of kernel/tree/year) and this fact substantiates my findings. The repeat experiments of Reber's[6,7] reversed beans confirmed the production of a greater weight of beans and an increase in weight ratio of beans to shucks. The flowers of Malvaceae and Bombacaceae are asymmetric[8,9] and the capsules developed from the left-handed *Bombax ceiba* flowers produced a slight excess of developed seeds. Of the 200 fruits gathered from known flowers of *Hibiscus esculentus*, those from left-handed flowers bore, on an

average, 5·27 per cent more seeds, although the difference is not statistically significant.

In vitro Production of Embryos from Anthers of *Datura*

Observations of natural phenomena such as adventive embryony and production of plantlets from the leaf margins of *Bryophyllum* support the view that although cells may differentiate and appear to behave differently, their genetic potentialities remain the same. As a corollary to this view, differentiation operates not through a segregation mechanism but due to selective and programmed suppression or stimulation of genic activity.

In recent years this view has been greatly strengthened by the use of *in vitro* culture technique, and the regeneration of perfectly normal plantlets from mature tissues of the stem and root has been demonstrated even in cases where such a phenomenon has not been observed in Nature. Thus buds differentiate under suitable treatment from tobacco pith callus[1], from stem callus of potato[2] and horseradish (*Armoracia*)[2,3], from root callus of *Isatis*[4], *Convolvulus*[5] and carrot[6,7], from bud scales of *Lilium*[8] and from embryonal callus of *Cuscuta*[9] and other plants. In several other instances embryo-like microscopic structures have been reported from callus masses, although their further development into plantlets has not been observed[10,11]. To the best of our knowledge, however, thus far there has been no report of the origin of embryos from anthers. The observation which we report here was made during attempts to grow callus from *Datura* anthers for an examination of cell multiplication in liquid suspensions.

Anthers of *Datura innoxia* Mill. growing wild in the university campus were sterilized with chlorine–water and planted in various nutrient media. The basic nutrient medium comprised Nitsch's or White's minerals and 2 per cent sucrose. This was supplemented with various growth substances such as indolyl-3-acetic acid (IAA, 10^{-6} M), kinetin (10^{-6} M), casein hydrolysate (1,000 p.p.m.), yeast extract (1,000 p.p.m.) or fruit juices like coconut milk (15 per cent), cherry juice (10 per cent), grape juice (10 per cent), litchi juice (10 per cent), pineapple juice (10 per cent) and plum juice (10 per cent) singly or in combination.

The inoculated anthers varied in maturity from the archesporial stage to mature pollen grains. However, the younger anthers did not grow in any of the media and eventually dried up. Those inoculated at the pollen grain stage showed vigorous proliferation on media containing 10^{-6} M indolyl-3-acetic acid and 10^{-6} M kinetin. The proliferations seen in Fig. 1 consisted of warty outgrowths, about 1 or 2 mm in diameter, sometimes arising all around the anther. In media containing both yeast extract and casein hydrolysate, proliferation occurred to a much lesser extent. All the proliferated masses grew satisfactorily on sub-culturing and have now been maintained for about 12 weeks.

Curious behaviour was observed in anthers implanted in media containing (1) casein hydrolysate (1,000 p.p.m. + 10^{-6} M IAA + 10^{-6} M kinetin, (2) coconut milk, (3) grape juice and (4) plum juice. For a long time these anthers showed no change at all and after 6–7 weeks the cultures were about to be discarded. Then, suddenly, numerous embryo-like structures projected out of the anther from all sides (Fig. 2). The embryos possessed root-shoot axes and cotyledons. Moreover, they were green and looked like perfectly normal embryos, with the only difference that most of them were polycotyledonous with as many as 10 cotyledons. Dicotyledonous embryos were also present, but in much smaller numbers. Many of these embryos have developed into normal seedlings. The effectiveness of different media in producing embryos varies. On media containing coconut milk and plum juice almost all the anthers showed the production of embryos. In the remaining two media only about 50 per cent of the anthers did so. In the basic medium, without added growth substances or extracts, no embryos were formed. Most of the embryos appear to be located inside the pollen sacs and are free-floating. They may have arisen from the pollen grains or from the connective tissue of the anther. Further work is in progress to ascertain this point.

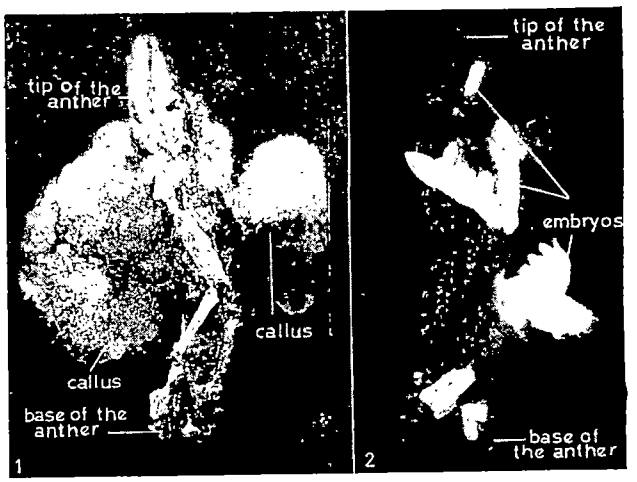

Fig. 1. Anther showing proliferation on basic medium containing IAA 10^{-6} M and kinetin 10^{-6} M
Fig. 2. Anther showing embryos from all sides on basic medium containing 15 per cent coconut milk

Agar-diffusion Technique for estimating Gibberellin Production by Plant Organs

So far, all published results relating to the gibberellin content of plants, or plant organs, have been obtained by various gibberellin-extraction techniques. This procedure is useful in the determination of the gibberellin content at any point in time, but it is often desirable to be able to estimate the rate of gibberellin production by various plant organs. In the course of our work on the gibberellin relationships of organs in the sunflower plant (*Helianthus*

annuus), we have adopted a modification of the classical technique of agar-diffusion. The method is simple and flexible and, as will be shown, it is reasonably sensitive and quantitative.

The plant organs are stood on, or 'plugged into', 1·5 per cent washed agar-gel blocks and left for a period of time to allow materials to diffuse from the cut surfaces into the agar blocks. The actual number of organs used, the way in which they are placed on the agar, and the size of the agar blocks can be varied to suit the particular tissues under study. The length of the diffusion period may be critical, and it is advisable to establish the most suitable time for the particular material under test. The diffusion can be carried out under a variety of environmental conditions, although in our work we have mainly used a régime of continuous light from fluorescent tubes at 22° C, under high humidity. A simple example of the method is shown in Fig. 1, where an apical bud of a young sunflower plant is plugged into a small agar cylinder (8 mm diam. × 5 mm high) standing on a 1-in. diam. aluminium planchet under an inverted glass vial.

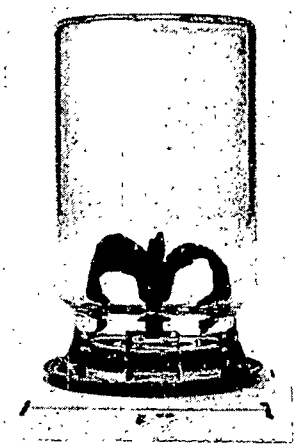

Fig. 1. Typical arrangement for agar-diffusion of excised plant organs

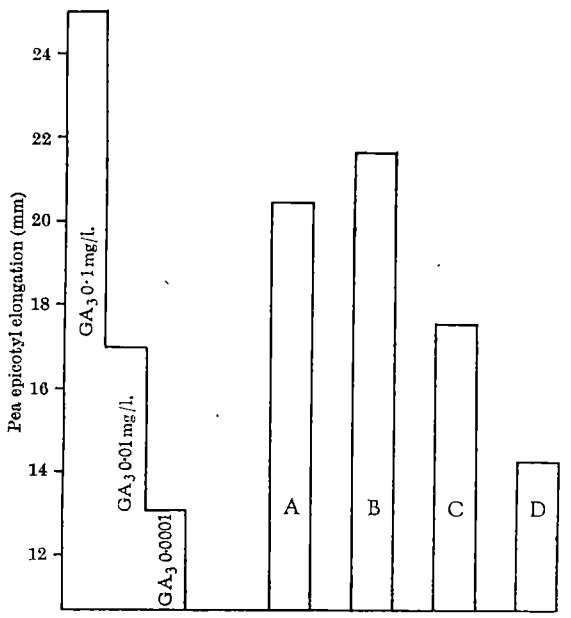

Fig. 2. Dwarf-pea epicotyl elongation assay of gibberellin-like materials obtained from agar blocks which had been in contact with fifty sunflower apical buds for varying periods of time. (*A*, 12 h; *B*, 24 h; *C*, 40 h; *D*, 12 h, followed by a period of 28 h without the apical buds present.) Elongation of epicotyls in the presence of known concentrations of gibberellic acid (GA_3) is also shown

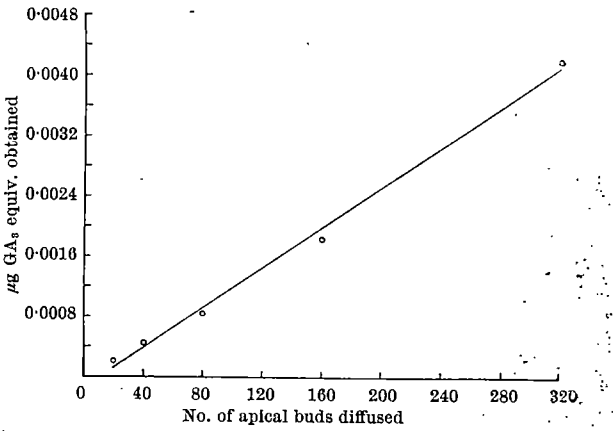

Fig. 3. Linear relationship between number of sunflower apical buds and amount of gibberellin-like material obtained from them by agar diffusion. Results expressed in μg GA_3-equivalents

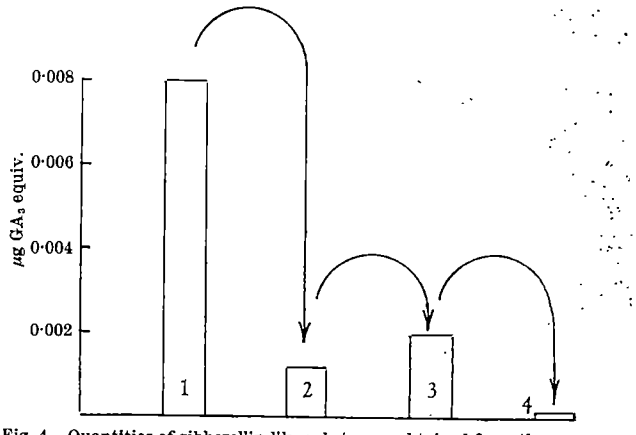

Fig. 4. Quantities of gibberellin-like substances obtained from the same sample of fifty sunflower apical buds during consecutive 12-h diffusion periods. The initial diffusion period was commenced immediately after excision of the buds

At the end of the diffusion period the agar blocks are frozen at − 15° C, the water phase of the agar gel, together with dissolved substances, freezing out. The frozen agar blocks are then extracted with absolute methyl alcohol at room temperature. The methanol extract is then drawn through a Buchner funnel and the remaining dehydrated agar is washed with more methanol. The methanol extract plus washings is reduced to an aqueous phase under vacuum at 35° C, and the aqueous residue acidified to *p*H 2·5 and extracted with ethyl acetate. The ethyl acetate fraction is then either reduced to a small convenient volume for paper or thin-layer chromatography, or reduced to dryness for gibberellin assay without chromatography. In the latter event, the dried extract can be taken up in water or other desired solvent.

With sunflower tissues, we have standardized the diffusion period at 18 h in the light at 22° C. Diffusion periods longer than 24 h have been found to result in a reduction of the amount of gibberellin-like materials in the agar blocks. This is seen in Fig. 2, where a comparison is made of the amounts of gibberellin-like substances obtainable from identical samples of 50 sunflower apical buds left to diffuse for 12, 24 and 40 h, and from agar blocks which had been in contact with 50 apices for 12 h and then left to stand out of contact with any plant tissue for a further period of 28 h. The assay used to determine gibberellin-like activity in this and other experiments reported here was a dwarf pea epicotyl-elongation test described previously[1]. It can be seen that most activity was recovered from the agar following a 12- or 24-h diffusion period, less being recovered after 40 h. The fall between 24 and 40 h would appear to be due to inactivation of gibberellin-like

material within the agar blocks, since there was a marked reduction in recoverable gibberellin-like activity when the agar was left to stand for a period of 28 h following a 12-h diffusion period. Fig. 3 shows the linear relationship between the number of sunflower apical buds diffused and the amount of gibberellin-like substances obtained, expressed in terms of gibberellic acid (GA_3) equivalents. It is likely that the amount of gibberellin diffusing out from an excised organ changes with time even under constant environmental conditions. That this occurs with excised sunflower apical buds is demonstrated in Fig. 4, which contains data obtained in an experiment where the same sample of 50 apical buds was transferred to fresh agar blocks at 12-h intervals. At the end of the first 12-h diffusion period activity equivalent to 0·008 μg GA_3 was obtainable from the agar, whereas at the end of the fourth 12-h period a negligible amount was present. Thus, the initial rate of gibberellin diffusion from the buds into the agar was not maintained. The reason for the decline is obscure; lack of respiratory substrate or of gibberellin precursor are possible factors.

The efficiency of this method for extracting the agar blocks has been evaluated by incorporating known amounts of GA_3 into 1·5 per cent agar blocks of the type used in these experiments, and estimating recovery of GA_3 by means of the dwarf pea epicotyl assay. Earlier experiments were conducted using a technique involving extraction of macerated agar blocks in absolute methanol, but without prior freezing of the agar. When this was done recovery rates of the order of 40 per cent or less were obtained; freezing the water out of the agar blocks before methanol extraction has raised the average recovery to 88 per cent in 30 experiments with a range of 72–100 per cent.

ENTOMOLOGY

Distribution of Alkaline Phosphatase in the Malpighian Tubules of the Desert Locust

Small quantities of alkaline phosphatase have been found in the malpighian tubules of several insect species. Histological investigations suggest that it is not uniformly distributed in the cells of the tubules but that some regions contain the enzyme while others do not[1,2]. This communication summarizes some observations on alkaline phosphatase activity in the malpighian tubules of the desert locust, *Schistocerca gregaria* Forsk, at different stages of development.

Three groups of locusts were chosen to represent immature, mature and aged stages in the life-history of the adult. The alimentary canal of each locust was carefully removed and histological sections were prepared of the malpighian tubules taken from the region of the cæca and posterior mid gut. Alkaline phosphatase was identified by the Gomori–Takamatsu technique[3] and controls stained simultaneously[4]. In each series a minimum of two hundred tubules were examined.

In sections from the region of the cæca there was a positive alkaline phosphatase reaction in 21 per cent of the tubules in immature locusts, 52 per cent in mature locusts and 62 per cent in aged adults. The corresponding values from sections prepared from the mid gut region were 22, 20 and 28 per cent. When present, the phosphatase tended to be localized at the inner border of the cells adjoining the lumen of the tubule, but in a few observations additional concentrations were observed at the base of the cells. Intracellular phosphate was identified in some of the cells which had shown a negative enzyme test.

These observations confirm that small quantities of alkaline phosphatase occur in the malpighian tubules of the desert locust but suggest that it is differently distributed in the proximal and distal portions of the tubules. Such variations may be due to the different functions of the two parts of the tubule[5]. The slight increase in phosphatase concentrations in the older locusts agrees with observations published on the ageing of vertebrate tissues[6], but the wide range of variation between the individuals within this group suggests that further investigations of their immediate physiological state are necessary before comparisons can usefully be made.

Multimodal Interneurones of Locust Optic Lobe

The auditory interneurones which ascend the ventral cord of the migratory locust have been traced forward only as far as the neck connectives[1,2]. Fibres which give a similar response can occasionally be found in the lateral parts of the protocerebrum or in the optic lobes by probing with indium-filled platinum-plated microelectrodes. They have not been found, although sought, in the corpora pedunculata. However, by probing in the optic lobe, higher-order neurones which give a different set of responses to auditory stimuli are commonly encountered. These also respond to vibration or touch stimuli of all kinds, to a wide range of visual stimuli via either compound eye, but only to high-intensity stimulation of the ocelli. The most easily found example is in the outer layers of the medulla in the optic lobe. Typically they consist of units which are presumably large because they give large spikes, with a background spike discharge ranging from 1 impulse per 10 sec to 10 per sec. Sensitivities to all modalities are low, compared with other units which respond typically to only one of the modalities. No evidence of association between inputs has been found, although sought. When the stimulus is repeated regularly at intervals of up to 10 sec, the response almost always declines in number of impulses, occasionally down to no response with irregular return of the response to some of the stimuli. The upper limit of repetition frequency varies greatly between units, or between what appear to be the corresponding units in different animals. Also, the rate of decline of the response varies greatly as between units for a standard frequency of stimulus repetition. Responses to different modalities adapt at different rates. Adaptation to a stimulus of one modality does not usually influence the response to a different modality of stimulus newly introduced, demonstrating an independence of inputs, and separate adaptation to each.

The same regional separation of adaptation is always encountered when a stimulus is introduced into a new part of the visual field when a different part of either eye has been adapted out by repetition. Effective stimuli are intensity changes, such as those caused by moving shadows rather than small movements at constant illumination; but the distinction between these types of stimulus is not clear for units with a wide field, within which separate small areas adapt separately. Some units respond at 'on', others at both 'on' and 'off'. These units, therefore, have some properties required of 'novelty units' for visual, as well as for other, stimuli. They have binocular wide-field coverage, and there is evidence, from

the adaptation investigations, that each part of the visual field (down to areas subtending a few degrees) has separate inputs. An anatomical correlation with large widely-ramifying horizontal fibres in the other layers of the medulla is probable. The units can be either efferent or afferent, depending on the stimulus. With auditory responses, no clear-cut discrimination of stimuli coming from the two sides of the animal can be found, although recordings have been made on scores of occasions from either optic lobe. Other characteristics of these fibres include: (*a*) unaccountable bursts of activity not preceded by any noticeable stimulus but sometimes associated with movement; (*b*) the persistence of the individuality of the parameters of the response over many hours, sometimes in units held for 3 days; although (*c*) after long periods of quietness in the dark the thresholds drop and activity is more persistent and more readily aroused; (*d*) after a pause of several minutes the first response is frequently very much more intense and sustained than when repetitions of a few seconds are used.

The function of these units is difficult to understand. Clearly they respond to any stimulus which would 'startle' the locust, and because they are multimodal they cannot be much use for specific responses. It may well be that all their normal responses, with repeated stimuli, are incidental, and only the large responses after a long pause may be 'effective', whatever that implies. In the absence of correlative behavioural response, the increased spike frequency is the only sign of a 'start' and, if it does represent an arousal, what then is aroused? From these and related investigations on insect neurones, it is apparent that there is a population of non-specific interneurones which can have many diverse inputs, all of which must be investigated before the unit is fully characterized. With reference to the part played by hearing in swarming and sexual behaviour it must be remembered that in these units the nature of the stimulus is not recoverable from the response of the unit alone, so purely auditory interneurones must lie elsewhere. The existence of these units, with widespread arborizations, implies that a response which appears at first to be of central sensory interneurone might on further examination be found to be modified by this non-specific system.

Some Aspects of Weevil Behaviour affecting Population Establishment

It has been recognized for some time that it is necessary to assess the significance of low-density pest populations in stored grain. These may be survivors from a treatment (probably pre-adult stages) or migrants entering hitherto uninfested material; either may give rise to larger populations. On the other hand, 'tolerable levels' of infestation may exist, below which a population would fail to establish itself.

To estimate the probability of a female in a sparse population being fertilized, 20 kg of English wheat, of 14 per cent moisture content, was stored in plastic bags into which single pairs of one-week-old virgin grain weevils (*Sitophilus granarius* L.) were released. Five replicate bags were set up for each of 4, 8, 12, 16 and 20 weeks at 25° C. After storage for these periods, the females were sieved off, dissected and examined for sperm. Two of the females examined after four weeks had been fertilized and four after eight weeks. All those kept longer than this had been fertilized.

It was apparent from this experiment that at 25° C a single pair could initiate a population. Furthermore, under field conditions, such initial densities would most likely escape detection. Two lines of investigation were therefore commenced: first, demonstration of sexual attraction in this species and, secondly, a long-term analysis of population dispersion in grain and in particular those factors influencing aggregation. Olfactometer experiments failed to give any evidence of intersex attraction, however, and attention was directed to discovering some feature of behaviour which might facilitate contact between adults of differing sex. Presence on the surface of the grain was compared for individual virgin and mated males and females of the same age. Ten one-week-old individuals of each category were taken from the same culture and isolated in 250 g of grain (14 per cent moisture content) at 25° C. The number found on the surface of the grain each day for ten consecutive days was recorded and the results are summarized in Table 1.

Table 1. Mean Number of Individuals per Day on the Surface of the Grain

	Virgin	Mated
Male	3·0	2·7
Female	2·6	1·0

The main conclusions are: (1) The mean number of females on the surface of the grain was significantly higher ($P < 0.05$) for the virgin than for the mated ones. Other investigations on this species have shown that the mated female spends a large proportion of her time below the surface boring in grain[1]. (2) The mean numbers of mated and unmated males on the surface of the grain were not significantly different. Among mated males, however, only in four cases was the same individual seen at the surface on two consecutive days, whereas in unmated males this occurred ten times, and in two cases the same individual was seen on the surface for up to five consecutive days. Other investigations on this species have shown that mated males are constantly changing their position in the grain, apparently at random.

Observation of individual behaviour therefore indicated that some mechanism does exist which facilitates contact on the surface of the grain between unmated adults of different sex.

Selection of some Strains of *Anopheles atroparvus* with Different Behavioural Responses to Contacts with DDT

Changes in the house-haunting habits of *Anopheles*, observed during campaigns of residual spraying with DDT, may be of various kinds. Moreover, they may interfere in a complicated way with malaria transmission[1]. Much attention has been directed in recent years to the appearance of strains showing a hyper-irritability towards the insecticide, leading to decreased insecticide contact and increased survival[2–5].

Although it is most probable that such strains originate by selection from a genetically mixed population, analysis is difficult in the absence of any information on the genetical mechanism involved and on the situation before spraying. Using the capacity to escape from an enclosed space as a criterion of irritation, it has proved possible in the laboratory to select two strains differing widely in this aspect, starting from a single Dutch strain of *Anopheles atroparvus*, isolated from the field and kept for two years in the laboratory. Both strains, at the end of the selection experiment, appeared to differ from the original colony (Fig. 1). The criteria utilized in selection were: (*a*) Escaping during 15 min from a horizontally-placed tube, lined internally with paper impregnated with DDT

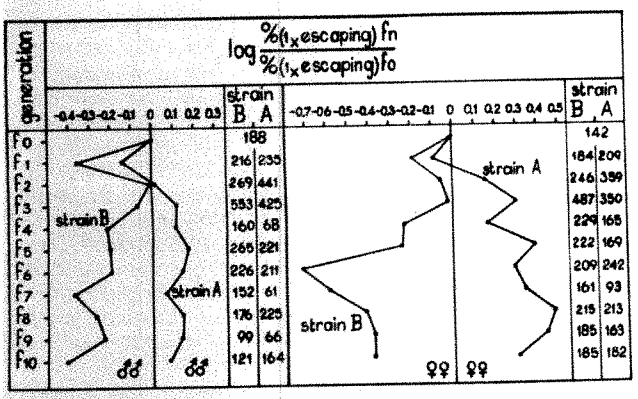

Fig. 1. Log $\frac{\text{per cent } (1\times\text{escaping})\ f_n}{\text{per cent } (1\times\text{escaping})\ f_o}$ of strain *A* and strain *B*.

Strain *A*, selected for escaping three times; strain *B*, selected for not escaping three times. Numbers of mosquitoes tested are given in the two columns to the right of each graph

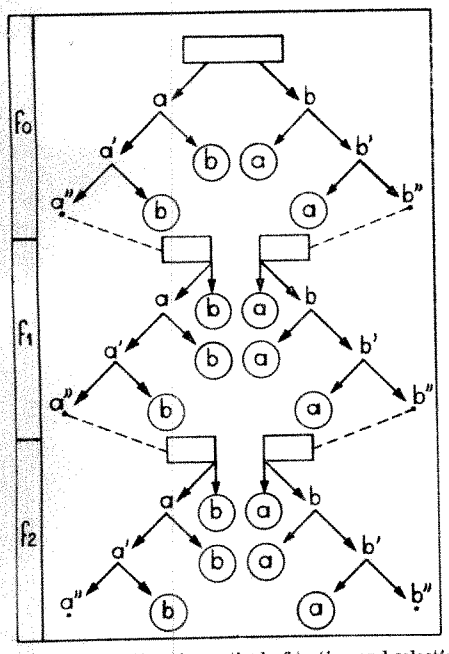

Fig. 2. Scheme illustrating the method of testing and selection, based on repeated testing and successive elimination. *a*, mosquitoes escaping; *b*, mosquitoes not escaping; rectangle, sample of mosquitoes; circle, mosquitoes to be eliminated

dissolved in 'Risella' oil. (*b*) Not escaping during the same time from the same tube. (*c*) Reacting identically in three successive tests with 24 h interval (Fig. 2).

Random reactions are largely excluded by the application of criterion *c* (Tables 1 and 2). This method of selection was first described in a paper by Beard[6]. The results of the selection are given for generations 1–10 inclusive (Fig. 1). It was realized that escape might be influenced as much by the natural activity of the mosquitoes as by the test substances, namely, DDT and its solvent, 'Risella' oil.

On testing these possibilities separately, it was found that selection for natural activity indeed affected the escape-rates (control tests, Tables 3 and 4). A definite irritation effect was found (Table 3), due to: (*A*) 'Risella' oil; (*B*) DDT dissolved in 'Risella' oil; (*C*) DDT crystallized on dry Whatman No. 1 filter paper.

The strains obtained show an identical difference in escaping in a vertical direction in tests done during 15 min from a cage measuring 50 × 50 × 50 cm, lined with paper impregnated with DDT dissolved in 'Risella' oil (Table 4).

Table 1. Percentage of Females escaping (Reaction *a*) in Generations *f4–f9* Inclusive, in three successive Tests done in Contact with 4 per cent DDT-impregnated Paper with Strain *A* (selected for Escaping Three Times; Numbers tested in Parentheses)

Test 1	Test 2	Test 3
50·5 (1,049)	59·5 (507)	62·7 (303)

Difference between Test 1 and Test 3: $\chi^2 = 13{\cdot}998$ $P = < 0{\cdot}001$

Table 2. Percentage of Females not escaping (Reaction *b*) in Generations *f4–f9* Inclusive in Three successive Tests done in Contact with 4 per cent DDT-impregnated Paper with Strain *B* (selected for not Escaping Three Times) (Numbers tested in Parentheses)

Test 1	Test 2	Test 3
90·4 (1,221)	93·6 (854)	95·6 (702)

Difference between Test 1 and Test 3: $\chi^2 = 16{\cdot}747$ $P < 0{\cdot}001$

Table 3. Percentage of Mosquitoes of the Original Strain and of the Strain selected for Escaping Three Times (*f8–f10*), escaping after Contact with Different Papers (Numbers tested in Parentheses)

Material tested	Percentages of mosquitoes escaping: Males		Females	
	Original strain	Strain *A*	Original strain	Strain *A*
Whatman filter paper impregnated with 'Risella' oil	14·0 (86)	60·5(151)	13·2(114)	51·9(106)
Crystallized DDT on dry Whatman filter paper	—	50·6 (87)	—	22·8(158)
Whatman filter paper impregnated with DDT dissolved in 'Risella' oil	54·8(188	65·2(164)	21·8(142)	43·4(182)
Dry Whatman filter paper	5·1 (99)	10·9 (46)	2·7 (73)	4·3 (47)

Table 4. Percentage of Engorged Females of Generations *f5–f9* Inclusive escaping within 15 min from a Cage with Dimensions 50 × 50 × 50 cm (Numbers tested in Parentheses)

	Paper impregnated with 4 per cent DDT in *Risella* oil	Dry Whatman paper
Strain *A*	65·3 (632)	19·7 (386)
Strain *B*	27·4 (995)	13·9 (540)

MICROBIOLOGY

Pimelic Acid as a By-product of Azelaic Acid Degradation by *Pseudomonas* sp.

In 1955 Wright *et al.*[1] demonstrated that pimelic and azelaic acids stimulate the biosynthesis of biotin in *Aspergillus niger*. Since then, three groups[2–4] of workers have established that pimelic acid is a precursor in the biosynthesis of biotin. It remained to be tested whether or not pimelic acid is a by-product of the microbial degradation of azelaic acid.

In our experiments we have used *Pseudomonas* sp., strain *W*, which utilizes azelaic acid as the sole carbon source. The organism was isolated from garden soil and grown in a medium containing mineral salts and azelaic acid. Whole cultures were acidified and continuously extracted with ether. From cultures in the exponential phase of growth, both azelaic acid and pimelic acid have been isolated in crystalline form. Pimelic acid was characterized on the basis of chromatographic properties, melting point, mixed melting point with authentic material and infra-red spectrum. Continuous ether extraction of the culture solution near the end of growth gave a mixture of acids in very small amounts and larger amounts of an unidentified end-product which behaves chromatographically like an acid, is brown in colour and has the consistency of an oil. In the light of the work previously

referred to, our investigation explains the role of azelaic acid in the biosynthesis of biotin.

This investigation was supported by U.S. Public Health Service research grant *HE*–04138–06 from the National Heart Institute.

Metallic Sheen in *Pseudomonas aeruginosa*

Hadley[1] noticed what he termed silvery patches either as haloes or crescent-shaped areas, around some corroded colonies in cultures of *Pseudomonas aeruginosa*. Several later workers[2–5] showed that these patches of iridescent metallic sheen were distinct from bacteriophage plaques. Warner[6] expressed the opinion that sheen was a sign of bacterial variation, and that variant colonies within the surface culture produced an oily or waxy metabolite which lysed the parent strain. Sierra and Zagt[7] attributed the phenomenon to lipolytic activity.

The production of metallic sheen is dependent on the composition of the solid medium on which the culture is grown. On a suitable medium, such as Oxoid nutrient agar No. 2 or blood agar, about half a large collection of *Ps. aeruginosa* cultures, but no other species of *Pseudomonas*, produced a sheen. Although it was generally possible to select a sheen-negative strain from sheen-producing cultures by picking single colonies, the production of sheen appeared to be an inherent property of strains of *Ps. aeruginosa* under natural conditions. The presence or absence of sheen has been shown to be a constant feature of cultures belonging to the same serological and pyocine-type that had been isolated from epidemiologically associated infections[8]; sometimes the production of sheen proved a useful 'marker' for the separation of two distinct strains which belonged to the same type.

Another observation with a possible application in the recognition of strains of *Ps. aeruginosa* was that certain cultures had the ability to inhibit sheen-production by some but not by all cultures of *Ps. aeruginosa*. Mayr-Harting (personal communication) also observed the presence of sheen-inhibiting as well as sheen-stimulating substances. In the course of an investigation of the production of pyocines[9] it was noticed that, when two different strains of *Ps. aeruginosa* were grown close to each other as streaks on a solid medium, the production of sheen by one of them was sometimes inhibited, although the growth was unaffected in other respects. It was thus possible to design a simple technique in which eight different 'indicator strains' were superimposed as streaks or drops on a lawn of a sheen-producing culture (Fig. 1). Several different patterns of inhibition of sheen production were observed. Such a test might be used, in combination with other typing systems, for the further sub-division of common types.

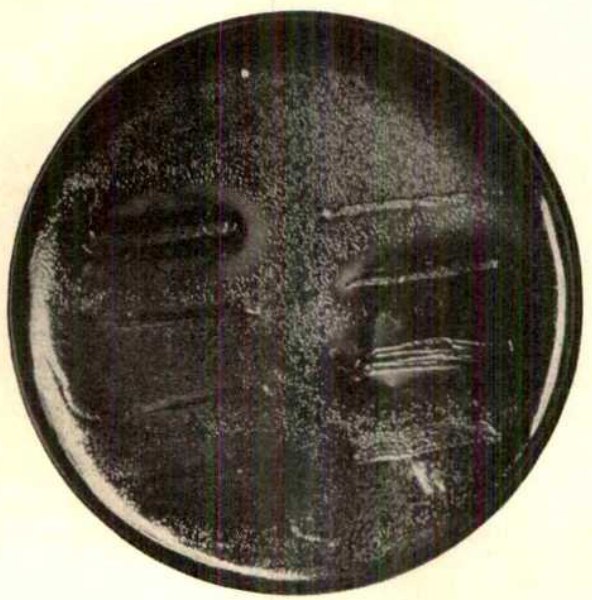

Fig. 1. Four 'indicator' strains showing the phenomenon of sheen-inhibition while four others do not show it

GENETICS

Chromosomes of the Ring Seal

This communication reports the chromosome analysis of the ring seal. The only report concerning the karyotype of an aquatic mammal prior to this was by Makino, who reported in 1948 the chromosome number of Dall's porpoise, *Phocoenoides dallii* True, to be 44 (ref. 1).

Through the courtesy of Dr. Carleton Ray of the Aquarium of the New York Zoological Society, fresh kidney tissue was obtained at the time of autopsy from a male ring seal, *Phoca hispida krascheninikovi* Naumov and Smirnov, an animal which inhabits the Bering Sea. The kidney tissue was removed, using sterile precautions, and was taken directly to the laboratory, where the surface was seared in a flame, the capsule removed, and the tissue prepared for culture by the technique reported in detail by Rappaport[2].

After three successive transfers, the cells were treated with colchicine for 5 h, expanded with hypotonic saline for 20 min, and fixed with acetic alcohol. The acetic alcohol cell suspension was air-dried on slides, and stained with acetic orcein. The slides were scanned, and representative metaphase plates which appeared to be unbroken and to contain little or no chromosome overlap were photographed.

Twelve suitable metaphase plates were examined. Each contained 32 chromosomes. A representative metaphase plate with its karyotype is shown in Fig. 1. The chromosomes were classified into seven groups. The first contains a single large chromosome pair with pronounced satellites. The second group, somewhat smaller than the first, contains 2 pairs with sub-median centromeres. Group 3 contains 6 pairs with median centromeres; group 4, 2 pairs with sub-median centromeres; group 5, 1 pair with acrocentric centromeres; and group 6, 3

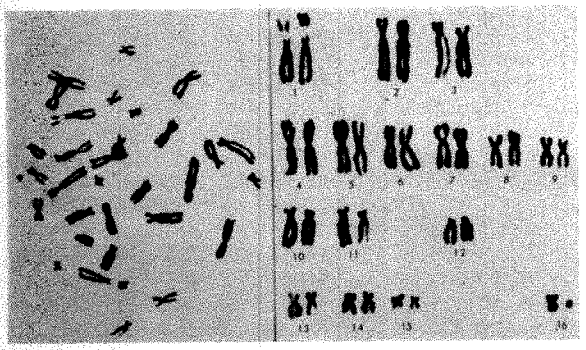

Fig. 1. Typical metaphase plate and karyotype of *Phoca hispida kraschenínikovi* Naumov and Smirnov

pairs with metacentric centromeres. Group 7, representing the sex chromosomes, contains metacentric chromosomes; one is similar in size and morphology to those in Group 6; the other is smaller than any other in the complement.

The small number of chromosomes, most of them metacentric, is consistent with Robertson's law which states that the more specialized animals contain chromosomes with an increased incidence of metacentricity, possibly due to centric fusion[3]. It is also possible that centric fusion may be related to the low chromosome number noted in many specialized species. Further karyological examination of aquatic mammals will aid in the study of the relationship between chromosome morphology and evolution.

AGRICULTURE

Lateral Drag of Chemicals in Soil by a Plough and a Rotavator

INFORMATION was needed on the extent to which a plough and a rotavator would drag soil-applied chemicals if ploughing or rotavating was done at right-angles to band treatments. A green fluorescent insoluble powder, of particle sizes between 5 and 10μ, was used as a tracer. This method had previously given good results in tracing the distribution of insecticides in soils[1]. In this instance the tracer was thoroughly mixed with powdered talc (not fluorescent) to simulate an aldrin dust. Strips of bare soil, in good tilth, 6 ft. long and 1 ft. wide, were marked out; the talc containing the tracer was evenly spread over these surfaces and lightly mixed into the top inch to prevent blowing. Three random core samples were taken from each strip to the depth to which the implements were set. The plough was started into the ground well before the strip so that it passed over at normal working speed and then on to a distance of 30 ft. It circled and went over the strip again in the same direction, continuing until all the treated area had been turned in. A similar procedure took place on the second strip with the rotavator. Ploughing was 8 in. deep, rotavation 6 in.

Three random samples were then taken 1 ft. from the edge of each strip up to 10 ft. and again at 15, 20 and 30 ft. As it seemed, from observation, that the rotavator might be throwing soil rearwards, samples were also taken 1 ft. from the back edge of that strip.

Samples were dried in the laboratory and put through a 1-mm sieve and then very thoroughly mixed. Soil from each position was evenly spread out in a Petri dish and the number of fluorescent particles observed in 100 random microscope fields was counted under ultra-violet light. The diameter of the field of the microscope was 2 mm. The three samples taken on each strip before ploughing or rotavating were examined separately to check on evenness of spread. The three samples taken after working from each foot distance away were bulked.

Table 1. COUNTS OF FLUORESCENT PARTICLES IN 100 RANDOM MICROSCOPE FIELDS FROM SAMPLES AT VARIOUS DISTANCES

Sample	Plough	Rotavator
Before ploughing	96, 98, 91	69, 72, 79
1 ft. back	—	57
1 ,, forward	55	8
2 ,, ,,	18	7
3 ,, ,,	14	4
4 ,, ,,	11	1
5 ,, ,,	7	—
6 ,, ,,	4	—
7 ,, ,,	3	—
8–9 ,, ,,	2	—
>9 ,, ,,	—	—

Clearly a considerable amount (of the order of 50 per cent) of the tracer was dragged by the plough for a foot, and up to about 10 per cent for 4 ft. After that only small amounts were found, and none after 9 ft. This does not imply that none of the tracer was carried more than 9 ft., but that the concentration beyond that was too low to be detected easily.

The results with the rotavator show that the main shift of material was a throwing to the rear of more than 75 per cent when the machine first went over the treated strip. An appreciable amount was taken forward up to 3 ft., but the total was only of the order of 25 per cent.

In the only other piece of work on soil drag of which I am aware, Njøs and Steenburg[2] used radioactive ammonium phosphate. At a distance of 25 cm from their plots the rotary cultivator carried with it less than 10 per cent of the tracer and this was also found for the plough at a distance of 100 cm. They did not test rearward throw. They also found that at 800 cm the carry-over was small for both implements, of the order of only 0·1 per cent. The results obtained by fluorescent tracers agree well with those from the use of radioactive material and they do not require highly specialized knowledge and equipment.

Effects of Low-temperature Storage on the Oxygen Uptake of Soil

A VALUABLE indication of the biological activity of soil is given by its uptake of oxygen or evolution of carbon dioxide. Large numbers of samples have frequently to be collected at the same time in survey work or in detailed field experiments, and immediate examination of the soils is not possible. Air drying has been widely used for storing soils, but on rewetting them a marked increase in respiratory activity is usually found[1–3].

Few experiments have been made with soils stored at low temperatures. Gooding and McCalla[4] found no difference in carbon dioxide production between previously frozen and unfrozen soils over several days. Although Antoniani *et al.*[5] and Soulides and Allison[2] found increased activity in previously frozen soils over short incubation periods the changes were smaller than with air-dried soils[2]. Freezing would appear to offer possibilities for maintaining respiratory activity in soil, and the effects of storage of four soils derived from different parent materials are described here.

Opouriao loam was collected in a tobacco field, and the other soils under grass–clover pastures, at a depth of

0·5–3 in. Some of their properties are given in Table 1. The soils were sieved through a 2-mm sieve, mixed thoroughly and stored in portions of about 350 g in polythene bags at −20° C. The soils were thawed at room temperature and allowed to stand for 24 h. Oxygen uptake was determined in Warburg flasks, the flask constants being calculated by the method of Webley[6]. The flasks were allowed 90 min to reach equilibrium, after which readings were made at 20-min intervals for 2 h. Any increase in activity which may have occurred on thawing the soils had subsided by the time the determinations were made, and constant rates of oxygen uptake were found with all soils.

From the results presented in Table 2 it is apparent that freezing had not changed the activity of these soils in any consistent way. Increased uptake of oxygen was found with two of the previously frozen soils, but values in general were close to those given by fresh samples. The measurements were not greatly affected by the period of storage.

It is conceivable that freezing may have lowered the numbers of viable micro-organisms[2] in these soils while rendering organic substrates more available for respiration, thus producing an apparent similarity between frozen and fresh samples. It would appear more likely, however, that their numbers remained essentially unchanged or that any decrease was counterbalanced by increased activity of the remaining organisms, for when excess glucose solution was added to the soils marked increases in oxygen uptake were obtained in both previously frozen and fresh samples.

These results suggest that storage at low temperatures may be suitable for maintaining the respiratory activity of other soils. Freezing has also been reported to maintain other biochemical activities such as nitrification in soil[7].

Table 1. Properties of Soils

Soil	Parent material	pH	Moisture (%)	Organic C (%)	Total N (%)	C/N
Waikakahi silt loam	Greywacke loess over marl	6·6	14	2·9	0·29	10
Judgeford silt loam	Greywacke loess	5·6	46	6·7	0·46	15
Kairanga silt loam	Alluvium from mixed sedimentary rocks	5·6	19	3·9	0·40	10
Opouriao loam	Alluvium from volcanic ash	6·0	13	2·3	0·21	11

Table 2. Oxygen Uptake of Fresh and Frozen Soils

Soil	Period of storage at −20° C (weeks)	Oxygen uptake, μl./g dry soil/h: Soil	Soil + glucose
Waikakahi	Fresh	7·4 ± 0·6	14·3 ± 0·5
	4	6·5 (89)	13·7 (96)
	9	6·8 (92)	14·5 (101)
	12	7·2 (99)	14·0 (98)
	16	6·4 (86)	14·8 (103)
	24	6·3 (85)	15·4 (108)
	Mean of frozen samples	6·6 ± 0·1 (89)*	14·5 ± 0·7 (101) *N.S.*
Judgeford	Fresh	8·8 ± 1·0	31·2 ± 1·0
	4	8·0 (91)	27·4 (88)
	8	7·1 (81)	28·3 (91)
	15	8·1 (92)	28·4 (91)
	24	8·0 (91)	29·3 (94)
	27	8·4 (95)	27·3 (88)
	32	10·0 (114)	25·6 (82)
	42	8·3 (94)	27·3 (88)
	Mean of frozen samples	8·3 ± 0·9 (94) *N.S.*	27·7 ± 1·1 (89)†
Kairanga	Fresh	7·0 ± 0·2	13·8 ± 1·2
	4	7·6 (109)	12·1 (88)
	12	7·8 (111)	12·5 (91)
	23	8·3 (119)	14·9 (108)
	Mean of frozen samples	7·9 ± 0·4 (113)‡	13·2 ± 1·5 (96) *N.S.*
Opouriao	Fresh	3·4 ± 0·2	9·1 ± 1·1
	4	4·7 (138)	9·9 (109)
	14	3·8 (112)	8·6 (95)
	Mean of frozen samples	4·3 ± 0·6 (126)*	9·3 ± 0·9 (102) *N.S.*

Soil (3·0 g) and water (3·0 ml.) or an aqueous solution of glucose (1·5 per cent; 3·0 ml.) were shaken continuously in Warburg flasks, with KOH solution (10 per cent; 0·2 ml.) in centre well, at 24° C. Four replicates were used for fresh and three for frozen soils at each period.

Results of fresh and mean frozen soils are means ± standard deviations. Figures in parentheses are values as percentages of fresh soils. Significance of differences between fresh and frozen soils, per cent: *N.S.*, $P > 5$.

*, $P < 5$; †, $P < 0{\cdot}1$; ‡, $P < 1$.

On the other hand, experiments with the four soils in this laboratory, to be reported elsewhere, have shown that mineralization of nitrogen was greater in most cases with previously frozen than with fresh samples[8] and that the activity of soil enzymes in hydrolysing starch or sucrose was lower in previously frozen samples. It would appear that the effects of freezing must be determined separately for each biochemical activity to assess its value for storing soils.

I thank Mr. I. R. Gibson for chemical analyses and Mr. D. C. McDonald for determining the specific gravities of the soils.

PSYCHOLOGY

Confirmation of Apparent Genetic Assimilation of Behaviour in *Drosophila melanogaster*

In a recent report[1] from this laboratory an apparent modification of food preference in *Drosophila melanogaster* was described, under the combined and opposing effects of natural and artificial selection. A deficiency in the design of that experiment was that the method used to measure food preference behaviour was confounded with a measure of the activity of flies. We have repeated this experiment with a new method of testing.

The general description of our methods can be found in the earlier paper. The new test method was as follows: A Y-tube was used into which the flies were introduced. One arm of the tube ended in a chamber in which peppermint-adulterated oatmeal-and-molasses agar was provided, while normal uncontaminated agar was placed in the chamber at the other end of the Y-tube. All flies were tested at the same time of day, and after fasting for a standard number of hours. The numbers of flies choosing each food were counted.

The results were identical with those in the earlier experiment. The most important results may be summarized thus. Flies selected for liking peppermint in each generation, and reared on it, produced a population which became strongly inclined to choose the peppermint food in the choice situation. Flies selected for aversion to peppermint, but reared on it, likewise produced a population which was strongly attracted to it. When the latter population was put back on normal food after eight generations they continued to show a preference for peppermint-scented food. Since the graphs of the data are so similar to those of the original experiment, we do not reproduce them here.

It seems plausible to say that since the experiments were begun from a new population of wild-type flies in each case, it is extremely unlikely that the effect is due to the trapping of a rare gene, and that it seems rather to be a genuine case of 'genetic assimilation'[2].

We thank the Medical Research Council for financial support for this work.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 2

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. E. R. Leach: "What are Social Anthropologists Trying To Do?"*

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (joint meeting with the Royal Aeronautical Society, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. I. Kanter: "N.A.S.A. Research and Technology Programmes in Space Navigation".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (joint meeting with the Science and General Division, at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. J. Ellison: "Modern Introduction to the General Theory of Electrical Machines".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Lost Sahara" (Colour films with commentary and introduction by Mr. A. R. Hanbury-Tenison and Mr. James Wellard).

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. A. Hart: "Research Project Evaluation".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Woolwich Polytechnic Chemical Society, at the Woolwich Polytechnic, Thomas Street, London, S.E.18), at 7.30 p.m.—Dr. J. Leggett: "The Photochemical Apparatus of the Chloroplast".

SOCIETY FOR VISITING SCIENTISTS (at the English-Speaking Union, Dartmouth House, 37 Charles Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Computers in Publishing". Chairman: Mr. Richard Clay. Speakers: Mr. C. J. Duncan, Dr. T. A. Margarison and Mr. Fred Simmons.

Tuesday, November 3

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. J. H. Bird: "Australia: Coast, Mountain, and Back Country".*

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1), at 5.30 p.m.—Mr. J. T. S. Gundry, Mr. B. Lees, Mr. L. K. Rendle and Mr. E. J. Wicks: "The Use of Ammonia for Reducing Air-Heating Corrosion at Bankside Generating Station, C.E.G.B."*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. R. M. Wynne-Edwards: Presidential Address.

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. W. Wharton and Mr. B. J. Rogers: "The Problem of Vestigial-Sideband Transmission and Reception".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. E. D. Bishop: "Stability and Instability". (Afternoon lectures for Sixth Form Boys and Girls from Schools in London and the Home Counties. Further lectures on November 4, 10 and 11.)

ROYAL MICROSCOPICAL SOCIETY (in the Lecture Theatre, Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. Dr. Ernst Ruska: "Very High Resolution in the Electron Microscope".

UNIVERSITY OF LONDON (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. S. Eilon: "Reflections on Management Science".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. R. Finlayson: "Comparative Pathology of Arterial Disease". (Fifth of fourteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

PLASTICS INSTITUTE (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Prof. C. E. H. Bawn, F.R.S.: "Recent Developments in Ionic Polymerisation".

Wednesday, November 4

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. L. C. Payne: "Clinical Computing".*

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Wellcome Building, Euston Road, London, N.W.1), at 3 p.m.—Meeting on "Toxic Substances in Air".

COLOUR GROUP (Great Britain) (in the Physics Department, Imperial College, Prince Consort Road, London, S.W.7), at 3 p.m.—Mr. K. Hacking: "The Relative Visibilities of Spatial Variations in Luminance and Chromaticity"; Mr. A. R. Robertson: "High Accuracy Colorimetry".

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 4.30 p.m.—Mr. S. V. Haves and Mr. S. A. Tobias: "The Project Method of Teaching Creative Mechanical Engineering".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. E. O. Willoughby: "A Push-Pull Parallel Aerial System for Navigation and Application to Communication Problems with Simple Methods of Side-Lope Cancellation".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (joint meeting with the Science and General Division, at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Training of the Industrial Engineer" opened by Mr. C. J. Foster.

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5.30 p.m.—Dr. F. Pasquill: "Turbulence and Mixing in the Atmosphere".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. G. Brodie (Illinois): "Human Jaw Growth and Tooth Eruption".*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, TELEVISION GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. B. W. Osborne: "U.H.F. Television Reception over Long Distance Paths".

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (joint meeting with the Oils and Fats Group, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. R. B. Wright: "The Use of Antioxidants in Fishery Products".

SOCIETY OF ENVIRONMENTAL ENGINEERS, PACKAGING GROUP (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Mr. D. C. Allen: "The Package Environment in Relation to Design Requirement".

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, W.C.1), at 6 p.m.—Mr. N. Veall: "Some Radioisotope Techniques for Cerebral Circulation Studies".*

Thursday, November 5

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m.—Discussion Meeting on "Symmetry Properties of Sub-Nuclear Particles" organized jointly by Prof. C. F. Powell, F.R.S., Prof. R. H. Salitz, F.R.S., Prof. P. T. Matthews, F.R.S., and Prof. A. Salam, F.R.S.

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (at the School of Pharmacy, 29 Brunswick Square, London, W.C.1), at 2.30 p.m.—Meeting on "Practical Problems in Detergency and Disinfection".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 4 p.m.—Prof. M. R. Fenske (Pennsylvania State University): "New Chemicals and Fuels by Oxidation".

MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Devices for Pricing the Use of Congested Roads" introduced by Mr. G. J. Roth.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. Uno Lamm: "Mercury Arc Valves for H.V., D.C. Transmission".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. I. C. Roddie: "Nervous Control of Limb Blood Flow". (Sixth of fourteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation".)*

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Dr. D. R. Scott and Dr. R. S. Azad: "Air Flow Measurement in Refrigerating and Air-Conditioning Systems".

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "How do we Design Against Brittle Fracture?"

UNIVERSITY OF LONDON (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 6.30 p.m.—"Latin America: Past and Present. Indian Civilization: Peru and the Incas".*

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Brunel College Chemical Society, at Brunel College, Woodlands Avenue, Acton, London, W.3), at 7 p.m.—Prof. B. C. L. Weedon: "The Synthesis of Polyenes".

Friday, November 6

CLAY MINERALS GROUP OF THE MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 11 a.m.—Scientific Papers. 4.45 p.m.—Annual General Meeting.

UNIVERSITY OF LONDON (at Birkbeck College, Malet Street, London, W.C.1), at 6 p.m.—Prof. G. Ekman (Stockholm): "Psychological Scaling. I: Direct and Indirect Scaling Methods".*

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. R. B. Wright: "The Practical Application of Antioxidants in Food, Pharmaceuticals and Polymers".

TELEVISION SOCIETY (in the Conference Suite, I.T.A., 70 Brompton Road, London, S.W.3), at 7 p.m.—Dr. R. W. G. Hunt: "Factors Affecting the Acceptability of Colour Reproduction".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. R. D. Keynes: "The Electric Eel".

Saturday, November 7

ASSOCIATION OF CLINICAL BIOCHEMISTS, SOUTHERN REGION (at St. James Hospital, Sarsfeld Road, Balham, London, S.W.12), at 2 p.m.—Scientific Papers and Demonstration.

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. I. W. Cornwall: "British Association Experiment of the Weathering and Preservation of Archæological Monuments".*

Monday, November 9

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Submarine Telephone Cables—Protection, Damage and Repair" opened by Mr. R. J. Halsey and Mr. N. E. Holmblad.

UNIVERSITY OF LONDON (at Birkbeck College, Malet Street, London, W.C.1), at 6 p.m.—Prof. G. Ekman (Stockholm): "Psychological Scaling. II: On the Psychological Function and Related Problems".*

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Capt. J. M. Loyd: "Across the Wahiba Sands".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Inorganic and Physical Chemistry in the Science Department, Birkenhead Technical College—The Director of Education, Education Offices, 63 Hamilton Square, Birkenhead (November 9).

University Lecturer (with a special interest in genetics, including microbial genetics) in Botany—The Administrator, Department of Botany, The University, South Parks Road, Oxford (November 10).

Lecturer and an Assistant Lecturer in the Department of Applied Mathematics and Theoretical Physics—The Secretary of the Appointments Committee of the Faculty of Mathematics, The University, Arts School, Bene't Street, Cambridge (November 11).

University Demonstrator in the Department of Animal Pathology, to assist with teaching and research in virology or morbid anatomy—Dr. T. D. Kellaway, Department of Pathology, The University, Tennis Court Road, Cambridge (November 11).

Lecturer or Senior Lecturer (with a science degree specializing in geophysics or related discipline and some research experience) in Geophysics in the Department of Geology and Mineralogy, University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Brisbane and London, November 13).

Lecturer/Senior Lecturer in Applied Mathematics at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 20).

Demonstrator (with a degree in science, agricultural science, veterinary science or rural science) in Physiology at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 27).

Chair of Geography at the University College, Dar es Salaam, University of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 30).

Lecturer in Mathematics and a Lecturer in Statistics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 30).

Lecturer (preferably with research interest in geophysics) in Physics at the University College, Dar es Salaam, University of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 30).

Lecturer or Assistant Lecturer in Biochemistry at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (November 30).

Senior Lecturer and a Lecturer in the Department of Mathematics University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, November 30).

Senior Lecturer or Lecturer (inorganic chemist) in the Department of Chemistry, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, November 30).

Lecturer (agricultural scientist with a sound knowledge of the Australian environment and with postgraduate training and research experience in ecology and plant physiology) in Agronomy at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 4).

Lecturer in Pharmacology at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 4).

Lecturers (3) in Physics at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 4).

Reader in Chemical Pathology at Westminster Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 7).

Chair of Psychology—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (December 31).

Assistant Director (with an honours degree in botany, a sound knowledge of two or more modern languages, the ability to write good English, and preferably some editorial experience) of the Commonwealth Bureau of Plant Breeding and Genetics—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Downing Street, Cambridge (January 15).

Agricultural Officers (with a degree in agriculture with, if possible, experience in agricultural extension work overseas, or a degree in agriculture including agricultural economics with, if possible, experience in economic investigations into peasant farming) in Bechuanaland, for agricultural extension work in African and European farming areas or economic investigations into peasant farming—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC. 213/19/01.

Biochemist or Chemist (with a good honours degree and preferably two or three years' research experience) for research on the nutritional value, in animal feed, of wheat and wheat products—The Director, The Research Association of British Flour Millers, Cereals Research Station, Old London Road, St. Albans, Hertfordshire.

Graduate Research Assistant (with an interest and preferably experience in steroid work) to assist a team investigating endocrinology of human growth (Dr. J. M. Tanner)—The Secretary, Institute of Child Health, Great Ormond Street, London, W.C.1.

Physics Technician (with G.C.E. "A" levels in mathematics or physics) or Radiographer for work on the clinical application of isotope techniques—The Assistant Secretary, University College Hospital, Gower Street, London, W.C.1.

Research Fellow (graduate with experience in the field of steroid biochemistry and preferably a knowledge of gas chromatography) in Steroid Biochemistry in the Department of Zoology, St. Bartholomew's Hospital Medical College, to participate in research on the male reproductive system and the effects of various agents such as exogenous hormones and ionizing radiation—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. AC/979.

Scientific Officer (with a good honours degree in physics or engineering) to study dynamics of air and droplets in and around foliage—The Secretary, National Institute of Agricultural Engineering, Wrest Park, Silsoe, Bedford, quoting Ref. N/64/ECD/25/6.

Senior Lecturer or Lecturer in Numerical Analysis—The Academic Registrar, Hatfield College of Technology, Hatfield, Hertfordshire.

FOR HIGH PERFORMANCE
in routine analysis and research

THE OPTICA CF4R

A High-Performance Double-Beam Recording Spectrophotometer with Autotimer Attachment.

The CF4R has the same monochromator and similar high resolution as other OPTICA spectrophotometers. When used with the Autotimer Attachment any one of six automatic programmes may be selected. Designed to take up to four sample cells and one reference cell, this outstanding instrument is ideal for enzyme studies, chemical kinetics, and batch sampling.

CF4R Range 185-700mμ (Standard)
Price £1650

CF4R Range 185-700mμ (With Autotimer)
Price £1900

(Linear Absorbance Recording for either model £50 extra)

This instrument is manufactured completely at our Works, and is installed and delivered free of charge.

Full details of the CF4R and other OPTICA spectrophotometers will be forwarded on request.

Standard Features

* Grating Monochromator
* Integrating Spheres
* Flat Bed Recorder
* Five Cell Capacity

The Autotimer Attachment gives these automatic programmes:

1. Single scan of one sample with automatic stop.
2. Repetitive scanning of one sample.
3. Repetitive scanning of one sample at preset time interval.
4. Single scan of four samples on same chart paper.
5. Records Absorbance/Time curve of one sample at fixed wavelength.
6. Records Absorbance/Time curve of four samples at fixed wavelength.

Service Centres at London, LARkswood 2603: Manchester, CENtral 0937 and Newcastle, Low Fell 75002.

TAS/OA.4

CLASSIFIED ADVERTISEMENTS

are charged at 12s. for the first line and 6s. per line thereafter. Lines in capitals or containing words in capitals 12s. per line. Semi-displayed £4 16s. per single column inch. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, Estrand, London.

APPOINTMENTS VACANT

AUSTRALIAN NATIONAL UNIVERSITY

INSTITUTE OF ADVANCED STUDIES
THE JOHN CURTIN SCHOOL OF MEDICAL RESEARCH
DEPARTMENT OF MEDICAL CHEMISTRY

Applications are invited from Chemists experienced in nuclear magnetic spectroscopy for appointment to a Senior Research Fellowship or Research Fellowship, in the Department of Medical Chemistry (Head: Professor Adrien Albert; senior research workers: Drs. D. J. Brown, D. D. Perrin, E. Spinner). The successful applicant would be expected to prosecute his researches in this field, and to spend about half of his time supervising the production and interpretation of n.m.r. spectra for other members of the School, in conjunction with a full-time technical officer (electronic engineer) who has been appointed to maintain and help operate the instrument (a Perkin-Elmer 60 Mc model), equipped for proton spin-spin decoupling, and with a mnemotron repetitive scanner.

The salary of a Senior Research Fellow is determined in the range £A2,900 by £A100 to £A3,460, and of a Research Fellow in the range £A1,980 by £A100 to £A2,680. The appointment is for three years in the first instance, with a possible extension to five years. Superannuation is on the F.S.S.U. pattern with supplementary benefits. A grant sufficient for travel both ways by the Research or Senior Research Fellow and his dependants is payable, and assistance with housing is provided.

Further particulars and information as to the method of application should be obtained from the Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or by writing direct to Professor Albert. The closing date for applications in Australia and London is December 1, 1964.

DEPARTMENT OF PHYSICS

UNIVERSITY OF WINDSOR
WINDSOR, ONTARIO, CANADA

Applications are invited for the following staff appointments:

1. Low Energy Nuclear Physicist. Preference will be given to candidates with experience in the use and operation of nuclear accelerators. The duties will include the planning of a spiral ridge cyclotron laboratory.

2. Theoretical Physicist. Preference will be given to candidates with interests in either low energy nuclear physics and nuclear structure or atomic collision phenomena.

In both cases the successful candidates will be expected to instruct in undergraduate and postgraduate courses and to devote a part of their time to research. The appointments may be made at the ranks of Assistant Professor, Associate Professor or Professor at which properly qualified candidates can expect salaries of not less than $8,000, $9,500 and $12,000 per annum, respectively.

Inquiries should be addressed to Dr. L. Krause, Head, Department of Physics.

UNIVERSITY COLLEGE OF SWANSEA

CHAIR OF MECHANICAL ENGINEERING

Applications are invited for the Chair of Mechanical Engineering. Special qualifications and interests in the fields of Applied Mechanics, Control Engineering or Thermodynamics are desirable. The Department of Engineering is soon to move into new buildings and the Professor will have the opportunity of equipping new laboratories. Active programmes of research in postgraduate teaching are already in existence.

Further particulars can be obtained from the Registrar, University College of Swansea, Singleton Park, Swansea, to whom applications should be sent by November 30, 1964.

Scientific Civil Service

RESEARCH FELLOWSHIPS

PRINCIPAL RESEARCH FELLOWSHIP between £1,890 to £2,640 annually. Tenable for 1 year to 3 years (with possibility of extension to 5 years).
SENIOR RESEARCH FELLOWSHIP between £1,420 to £1,755 annually.
JUNIOR RESEARCH FELLOWSHIP between £975 to £1,310 annually.
Both tenable for 3 years.

EXAMPLES OF CURRENT VACANCIES

ROYAL AIRCRAFT ESTABLISHMENT, (Radio Department), Farnborough, Hants: PRINCIPAL FELLOW for research on Aerials and Propagation, e.g., general theory of active and passive aerials and propagation of electromagnetic waves; statistical theory of communications; data processing, coding and modulation; circuit theory; acoustical transducers and propagation.

ADMIRALTY RESEARCH LABORATORY, Teddington, Middlesex: PRINCIPAL FELLOWSHIP for Physicist or Applied Mathematician. Wide choice of subject within the fields of Oceanography and underwater Acoustics offered. Exceptional facilities.

CHEMICAL DEFENCE EXPERIMENTAL ESTABLISHMENT, Porton, near Salisbury: In a small team engaged on Operational Assessment of the military threat posed by modern C.W. techniques and the evaluation of defensive measures to combat it. The work requires an ability to look ahead, envisage possible lines of future development, and subject them to critical analysis and appreciation and involves the design of experiments to test theoretical or practical aspects and the interpretation of the results for service use. (Senior).

BUILDING RESEARCH STATION, Garston, Watford, Herts:
For the theoretical study of semi-infinite heavy elastic bodies perforated by holes and slots in connection with civil engineering earthwork construction. (Senior).

Fellowships in these and other establishments are available in most scientific disciplines. For a Principal Fellowship a candidate must produce evidence (including published work) of a considerable period of fruitful research and be accepted as a leading worker in his/her field. For a Senior or Junior Fellowship a first- or second-class honours degree is normally required, plus two years' postgraduate research (3 years for Senior Fellowships) during which a high standard of research ability must have been demonstrated.
F.S.S.U. terms. State age and qualifications, quoting S/570.

SCIENCE MUSEUM

London, S.W.7

Pensionable posts as follows:
(a) Senior Research Assistant in the Library. Minimum age 30.
(b) Research Assistant, initially in Chemistry Department. Minimum age 20.
DUTIES: (a) cataloguing scientific and technical literature; preparing bibliographies; guidance to readers. (b) planning and preparation of special chemical exhibitions and compiling publications on Chemistry Collections.
QUALIFICATIONS: (a) normally degree, Dip.Tech. (or equivalent) in an Engineering or Science subject and scientific library experience. Knowledge of foreign languages desirable. (b) normally degree, Dip.Tech. (or equivalent) in a Science subject, preferably Chemistry. Experience of modern laboratory techniques and museum experience are advantages.
SALARY (Inner London): (a) £1,748 to £2,208. Starting salary may be above minimum. (b) £673 to £1,160 or £1,274 to £1,549, according to age, qualifications and experience. Promotion prospects.
Closing date November 16, 1964. (Reference: S/6019/64).

OVERSEAS GEOLOGICAL SURVEYS

MINERAL RESOURCES DIVISION
Gray's Inn Road, London, W.C.1

SCIENTIFIC OFFICER / SENIOR SCIENTIFIC OFFICER required in the Chemical and Ceramic Laboratories to undertake research on the applications of mineral raw materials to ceramic and cementitious products. Previous experience desirable.
MINERAL ECONOMIST (graded SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER) to study the distribution, production and trade requirements of useful minerals, and to compile reports and monographs on particular minerals. Qualifications in Geology, Mining Geology or Economic Mineralogy and practical experience of the mineral industry required.
The appointments are permanent and pensionable.
Closing date November 23, 1964. (Reference: S/52-53/OGS).

HOME OFFICE

SCIENTIFIC ADVISER'S BRANCH
London

MATHEMATICIAN OR PHYSICIST (graded Senior Scientific Officer) for pensionable post concerned with the application of science to the problems of policing and crime. Candidates should have a knowledge of recent developments in the use of operational research techniques, including field experimentation, and the inclination to apply a wide range of these techniques as well as the ability to interpret the methods to non-technical personnel at all levels. Considerable relevant postgraduate research experience and the ability to analyse data are essential.
Early application advised. (Reference: S/53/HO).

PATENT OFFICERS PATENT EXAMINERS

PATENT OFFICERS, in Ministry of Aviation, are concerned with obtaining patent protection for inventions arising from government scientific research and for operating the statutory provisions for the government's use of patents.
PATENT EXAMINERS, in Patent Office, London, investigate patent applications against the requirements of the Patents Act and are responsible for the nation's system of patent awards.
QUALIFICATIONS: Degree or Dip.Tech. with first- or second-class honours in science, mathematics or engineering or full corporate membership of a professional institution. Age normally under 33. Specialized training given. Vacancies for mathematicians as Patent Examiners in the Patent Office are limited at present to those mathematicians who have studied physics or a technology.
SALARY: Inner London rate £885 to £1,910 with special advance points. Starting salary may be above minimum. Pensionable appointments with excellent promotion prospects. (Reference: S/128).

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

SALARIES: S.O. £815–£1348
(Increments and special £95 award for approved post-grad. experience).
S.S.O. £1481–£1825
(Starting salary may be above minimum).
Salaries are supplemented in the London Area.

QUALIFICATIONS:
S.O.: 1st or 2nd Class Hons. Degree or Dip.Tech. in appropriate subject. Age under 29.
S.S.O.: As above plus at least 3 years postgraduate research. Age normally 26–31.

APPLICATION FORMS for the above appointments and a free booklet entitled "THE SCIENTIFIC CIVIL SERVICE" are available from Civil Service Commission, Savile Row, London, W.1.

THE SCIENTIST'S CHANGING ROLE IN WORLD POLITICS

AN address, entitled "The Changing Role of Scientists in International Affairs", was delivered by Byron L. Johnson to the Sigma Xi Chapter of Colorado State University, and is published in the *American Scientist* (June, 52, 138*A*; 1964). Mr. Johnson discussed the varied functions which the scientist has come to assume in society, more particularly when, associated with the government in some capacity, he has some responsibility in the relations between one country and another. He mentioned the Pugwash meetings, but only to stress the need of such discussions if we are to restore the essential minimum of international confidence and trust without which successful negotiation is impossible. Apart from indicating the various parts the scientist can now play in international affairs, however, he was content to insist that the scientist must continue to pursue truth with singleness of purpose, as well as being a full participant in human affairs, understanding and supporting the humanities and the social sciences as well, and taking a completely human view of human beings. While he admitted the existence of a division, in government and in the university, between science and the humanities, with imperfect communication between them, he regarded the idea of 'two cultures' as an exaggerated dichotomy and believed that ultimately the two will blend.

Mr. Johnson indicated some of the tensions which the nationalist pressures of politics have put on the scientist and emphasized that the role of the scientist has been largely dictated by the conception of the national interest, but he did not in this address do more than hint that the scientist might render much more constructive and far-reaching contributions to human welfare if he were able himself to formulate the questions and suggest priorities for the allocation of resources. Mr. Johnson gave a further reminder that the solution lies, not in the provision of unlimited resources for research, but in the wise selection of objectives. If scientists are to play the part of advisers over a wide range of topics, and assist in the formation of public policy, their advice should be disinterested as well as authoritative. However, when he suggested that some scientists might serve in elective office, since public policy requires informed judgment in scientific matters, he did not recognize that in doing so the scientist becomes primarily a politician, responsible for decisions that are none the less political because they are determined partly on scientific considerations.

Dr. Caryl Haskins's Elihu Root Lectures are of a different order*. They attempt to review the direction and nature of some of the trends of scientific and technological change as they affect aspects of the foreign policy of the United States to-day, and as they may be expected to influence it in the future. Much of its thought is to be found in his reports as president of the Carnegie Institution of Washington for 1960–61 and 1961–62 and, as with those reports, his insight and wisdom are as refreshing to the reader in Britain as in the United States. The book should, once and for all, dispose of the idea that science and foreign policy are things apart, and passages in it bear closely on some points in the recent Plowden Report on representational services overseas (*Nature*, 202, 1039; 1964).

This relation between science and technology and foreign policy is well outlined in the introductory chapter to the book, and throughout the book the emphasis is on the forces of science and technology in relation to the internal strength and development of peoples, on their binding force among peoples and on the significance of technology and science for the emerging nations of the world. He then considers science and technology in relation to somewhat more advanced 'intermediate' nations in the technical, economic or political sense, such as Pakistan and Indonesia, before finally considering some scientific and technical aspects of international solidarity in Western Europe, and the nature and position of science and technology in the U.S.S.R. and China.

From the outset Dr. Haskins makes clear two personal biases which determine his whole approach. The first, which will be familiar to readers of his presidential addresses, is that the scientific revolution of the West, encompassing the years from Galileo and Copernicus to the years following Newton, has a meaning for the present day and for the new nations which is far more than historical. He believes that it is of great contemporary interest for three compelling reasons. First, it brought to the West, and can now be expected to bring to others in the future, a world view so radically new that it may well transform the outlook of those who experience it. Secondly, it brought for the first time, and may well bring again elsewhere, the real conviction that not only can significant aspects of the laws of Nature be understood by man, but also that they can be effectively used for man's practical gain. Thirdly, and most fundamental, our society, so dominated by science and technology, sets an overriding value on the search for truth, defined not only in the context of viable and intellectually satisfying propositions, but ultimately as the faithful description of our natural and swiftly changing social worlds as we can best delineate them.

This commitment at a very deep level to the search for truth as an overriding value involves social consequences as well as a powerful commitment to the scientific way. So long as a society considers truth in this light, and so long as the search for truth has a high value, that society harbours powerful incentives to remain dynamic and flexible. It is compelled for that very reason to set a high value on, and to protect, the independent and original mind, for it is on such minds that the effective search for truth depends. This notion of truth and the valuation of the search for truth, both linked so closely to the scientific concept, do much to ensure that a society remains flexible and preserves, in contrast to the traditional society, the power to evolve.

Dr. Haskins's second bias is that, closely woven and closely interdependent as are science and technology in our civilization to-day, and much as we take their intimate relation for granted in all we do, they are significantly different in origin and nature. This idea also Dr. Haskins has developed in his presidential addresses, and in this book he further shows how important the difference may be for the new nations, especially in respect of technical assistance. Indeed, probably the major importance of the

* *The Scientific Revolution and World Politics.* By Caryl P. Haskins. (The Elihu Root Lectures, 1961–62.) Pp. ix + 115. (Published for the Council on Foreign Relations by Harper and Row, New York and Evanston.) 3.50 dollars.

book lies in its clarification of some of the wider issues to be considered in giving technical aid to the new nations. Dr. Haskins would not claim that much that he says is original, but the issues that arise in the impact of technology on the emerging nations and their implications for technical aid have rarely, if ever, been presented more brilliantly, more lucidly, nor, be it added, more urgently.

The chapter in which he discusses the implications of the scientific revolution for the new nations is no less brilliantly presented. He makes essentially all the points which Dr. S. Dedijer made last year in his article on underdeveloped science in under-developed countries (*Nature*, 201, 1153; 203, 1313; 1964), but the chapter is equally a valuable contribution to the debate on scientific change which has continued since Dr. A. C. Crombie asked his searching questions at the Symposium on the History of Science at Oxford in July 1961. Dr. Haskins's deep understanding of the needs and problems of the developing nations is matched by his appreciation of what is at stake, the urgency of the situation, and the bearing of technical aid on scientific and technical advance generally.

Consideration of the relations of science and technology to world affairs even in the context of the developing nations is imperative, not merely from the point of view of humanity itself, but of world stability and world order Besides possibly helping the emerging countries at the most practically significant level, it could contribute to a clearer comprehension of the operation of social forces centring about scientific and technical change which are at present little understood, but which in their consequences could affect dramatically the whole configuration of world power in the years ahead. Even in Britain the relation of social forces to scientific and technical change is as yet little understood, and Dr. Haskins can well write that never in world history can such understanding have been more important than it now is and will continue to be in the age before us—an age of which an inevitable symbol will be the comprehension of scientific and technical phenomena on a far larger scale than ever before, and a new order in their control.

In the three chapters comprising the second part of the book, "Beyond the Scientific Revolution", Dr. Haskins does not touch quite the same heights, but he is no less stimulating, and what emerges most clearly from his analysis of the needs of such nations as Pakistan and Indonesia is the demand which effective technical aid makes on clear and critical thinking. Technical aid is no field for facile generalizations or political catchwords: each problem demands treatment with means appropriate to the purpose to be served, not with formula devised to deal with other situations or even with a general problem. This is irksome to the politician or administrator but it is vital for success, and while it may demand much of the scientist or technologist it is in line with his whole training and outlook. Some of Dr. Dedijer's observations, addressed to the leaders of the emergent countries, could not be better underlined.

Of Western science and the growing international co-operation in research and education, Dr. Haskins observes that international institutions must be firmly based on national institutions, and that the level of education and the formation of coherent and effective national policies for the support of science, together with the development of appropriate professional organizations, are essential factors. He looks briefly at all that this implies for the United States before considering, in conclusion, the problems presented by Soviet Russia and by China. Here, he admits that he is on less certain ground, but his conjectures are reasoned and shrewd, optimistic rather than pessimistic. Not everyone will agree with his judgement, nor will his questioning of the magnitude of the effort being devoted in the United States to the field of space research and a lunar landing be everywhere applauded. None, however, can lightly dismiss his searching question whether, in the long run or in the critical view of the world, spectacular space achievements command more enduring respect than outstanding success in bringing assistance at an effective level to those countries which need it most acutely. The context in which the question is poised epitomizes the theme of the whole book.

TRAFFIC PROBLEMS AND THE COUNTRYSIDE

THE pamphlet entitled *Traffic in the Lake District** recently issued by the Friends of the Lake District is a timely contribution to considerations of a problem which has much wider implications than the future of the Lake District as we now know it. The pamphlet was inspired by the Buchanan Report on *Traffic in Towns* (*Nature*, 201, 1059; 202, 219; 1964) and, while it is concerned essentially with one particular aspect of the problems created by the rapid expansion of motor transport—which is estimated to rise from about 10·5 million vehicles early in 1963 to 18 million by 1970 and 27 million by 1980—it directs attention to a problem which threatens the countryside in general and could destroy alike the whole purpose of national parks and nature reserves. Indeed, the problem is one that calls for forethought and consideration in all regional planning represented by such plans as have been outlined for Scotland, for the North-East and the South-East, and perhaps especially in such projects as the Channel tunnel.

* Friends of the Lake District. *Traffic in the Lake District*. Pp. 11. (Ulverston: Friends of the Lake District, 1964.)

The Friends of the Lake District have long foreseen the danger, and as far back as 1938 pointed out that, unless the development of motor transport and roads was checked, the Lake District would cease to be a place of quiet and refreshment. Again in 1960 they re-stated the problem and its dangers in a full analysis, showing that widening and straightening roads only attracted more cars, so that the process proved self-defeating. The most casual observer in any part of Britain is, indeed, likely to be aware of country roads which have been greatly improved to allow for the traffic they carry, but which have become more and not less dangerous because of the temptations to excessive speeds.

The case for much greater intelligence in road policy in country districts and for a livelier appreciation of the purposes to be served scarcely needs to be argued, though undoubtedly there is a considerable task of education to be undertaken, both among the general public and among highway and local authorities. So far as the Lake District is concerned, however, the present pamphlet once more puts forward convincingly the argument that the Lake

District should be subject to treatment quite different from that which might well be appropriate in more densely populated areas. The Friends of the Lake District believe—and with some justification—that popular opinion now inclines towards a sane policy. Moreover, they are prepared to accept that to a large extent the existing road system in the Lake District is adequate on most days of the year and that some delay and congestion must be tolerated by the motorist at week-ends and holidays as part of the price to be paid for the preservation of the traditional character and essential value of the Lake District.

The pamphlet begins by quoting the concern expressed by the Minister of Transport as to the possible effect on the Lake District of a direct link between the M6 motorway and Manchester. It also includes the observation by the Minister of Housing and Local Government, made at a National Parks Conference, that the more congested Britain becomes the greater will be the need for oases of peace and quiet, such as are provided by the parks. The danger is that this relatively small-scale and often fragile beauty may be destroyed by the crowds who will want to enjoy it. In the first review of the development plan of the National Parks Board the Lake District Planning Officers expressed the definite view that this was just what was happening. In the Lake District National Park this problem dwarfs all others. The pamphlet quotes the warning given in the Buchanan Report of the menace to our civilization that the motor-car in its collective aspect represents, and insists that, unless the greatest care is exercised, the countryside of Britain will be ruined by the end of the century.

By an accident of geography the Lake District escaped the full effects of the Industrial Revolution a hundred and fifty years ago: its isolation has now been ended and only definite and planned intervention is likely to avert its ruin. To reshape its roads in an attempt to allow all imaginable holiday traffic to pass freely and quickly would destroy the essential character of the Lake District valleys, but, if highway authorities are to cease to think only of road widening as a means of coping with increasing traffic, national policy seems imperative. The proposals for widening the road over Dunmail Raise, between Kendal and Ambleside, and up the Langdale valley, to which the pamphlet refers, are appalling in their implications, yet at present the highway authorities have a virtually uncontradicted say in all that concerns roads in the Lake District. The folly of failing to provide the national park authorities with effective powers could scarcely be better illustrated. Moreover, in laying down standards for the width and form of construction for roads feeding into or debouching from motorways, the Minister of Transport has not faced the implications of his own standards.

Here again, the Lake District roads need critical consideration in their special context rather than in the national plans for roads in general, and this could apply elsewhere in areas of special scientific interest or outstanding natural beauty, in other national parks, in nature reserves, etc. The keynote of the pamphlet, however, is not simply the urgency of the situation: it is above all a plea for thought—for the kind of critical forethought of which Lord Brain was thinking when he reminded us in his presidential address to the British Association at Southampton (*Nature*, 203, 903; 1964) that we have still no population policy. Ultimately this problem is a derivative of population, as well as other changes, in Britain, and the Friends of the Lake District do well to call for a pause in order to think quietly about what is being done and where we are going. In particular, they urge the Minister of Housing and Local Government, who carries the major share of effective responsibility in the matters concerned (including grants to the highway authorities), to commission something on the lines of a Buchanan Report on traffic problems in national parks. Certainly the body responsible for such a report should offer recommendations for easing traffic difficulties while retaining unimpaired the heritage of natural beauty which the parks were created to preserve.

Support for this view and its implications is not hard to find. Although Prof. C. Buchanan was concerned in an inaugural address, entitled "Transport and the Community" (now published†), with transport in towns, his concept of 'environmental capacity'—that any urban area has a finite capacity for motor traffic according to the environmental standard selected—is applicable to national parks, nature reserves, the coast or areas of plain countryside if certain environmental objectives are to be secured. This obviously requires further consideration, quite apart from decisions about the objectives and the price which can reasonably be paid to achieve them, but it is interesting to note how Prof. Buchanan relates the problem to that of the population explosion also referred to by Lord Brain.

Prof. Buchanan directs attention, not simply to the expected rise in population of at least 20 million in 40 years, to the quadrupling of the number of motor vehicles, the intensification of the demand for industrial productivity, but also to the extensive demands for new or enlarged facilities for recreation—all of which may cause severe pressures within the life-time of many young people now at college. He suggests that we might begin now by making a few basic global calculations as to how the population should best be distributed if broadly defined standards of living are to be secured in the various localities. Even in dealing specifically with problems in towns, his suggestions are addressed to individuals as well as to local and transport authorities, and some have their rural connotations. This is especially true of what he has to say about professional collaboration, which could well be a decisive factor. Obviously it provides the basis of such schemes as the Solway Barrage proposal of Dr. R. L. Drew, or the Morecambe Bay Barrage proposal now under investigation: balanced plans are only possible as a result of collaboration between those with such skills as the architect, engineer, planner, surveyor, sociologist and economist. However, as Prof. Buchanan also notes, collaboration would be required in quite a new spirit between numerous local authorities and public bodies, both in the preparation of plans and in their continuing implementation.

Nor is this all. Such co-operation is very necessary at ministerial level, between such Ministries as those of Transport, Housing and Local Government, Power, Industry, Trade and Regional Development, and Education and Science. Meanwhile, the danger persists that the position may be hopelessly prejudiced by sporadic and independent action or decisions. While such effective collaboration may lie in the future, certain Ministers, like those of Transport and of Housing and Local Government, do possess sufficient powers to restrain encroachments such as 'improvement' in the Lake District threatens. It would be intolerable if those powers were not used with wisdom, boldness and energy. Action taken to provide

† *Transport and the Community.* (Inaugural Lecture, February 18, 1964.) By Prof. Colin Buchanan. Pp. 175–193. (London: Imperial College of Science and Technology, 1964.) 2*s*. 6*d*.

the county councils with the powers suggested by Prof. Buchanan could be beneficial in rural areas. His lecture follows the lines of his earlier larger report, *Traffic in Towns*, and is a further stimulus to the critical and imaginative thinking that is urgently needed if the needs of a civilized community are to be met in the Britain of to-morrow. The study conference last November, *The Countryside in 1970*, like the preliminary enquiry made for the Royal Society of Arts into the *Impact of Industry on Amenities in the Countryside*, is an indication of the awakening to which the Friends of the Lake District refer. Prof. Buchanan's lecture and the pamphlet *Traffic in the Lake District* underline the closing words of the report on the enquiry *Industry and the Countryside*: "the frightening thing about the present day is the rate of change". Whether from the point of view of amenity or of natural resources, effective action on at least regional if not national lines is imperative and should be based not on sectional views but on the interests of the community as a whole.

TROPICAL GEOGRAPHY

Geographers and the Tropics

Liverpool Essays. Edited by Robert W. Steel and R. Mansell Prothero. Pp. vii+375. (London: Longmans, Green and Co., Ltd., 1964.) 47*s*. 6*d*. net.

THE twentieth International Geographical Congress, held in London during July 20–28, 1964, and attended by some 2,200 delegates, was preceded and followed by a number of specialist symposia at universities throughout the British Isles, at which small groups gathered for exchange of views. Under the leadership of Prof. R. W. Steel, whose name is rightly associated with geographical research in tropical Africa, the meeting at the University of Liverpool was devoted to the problems of tropical geography. This collection of fourteen essays was published to mark the occasion: the authors have all been associated in some way or other with the Department of Geography at Liverpool. Apart from the fact that the City and Port of Liverpool have always had close associations with many and varied tropical countries, this is the only unifying factor. Indeed, the collection illustrates the quite remarkable diversity of interest of geographers working on tropical problems.

In his introductory essay Prof. Steel reviews geographical work with special reference to tropical Africa and gives a valuable selective check list of 160 works published over the past thirty years. Physical geography is represented by P. H. Temple (Makerere University College) on change in the level of Lake Victoria; E. M. Driscoll on landforms in Northern Australia; Dr. S. Gregory deals with rainfall in Mozambique, and Joan M. Kenworthy with water resources in East Africa. Prof. Paul Wheatley, now at the University of California, Berkeley, devoted his period in the University of Malaya at Singapore to acquiring a proficiency in reading Chinese both modern and medieval. A rich field of original material has thereby been opened to the Western World, and he writes on Chinese knowledge of East Africa prior to A.D. 1500 in a scholarly and fully documented essay—the longest in the collection.

While the significance of the mobility of labour in sparsely populated tropical Africa is well known, Dr. R. M. Prothero has set out to study systematically the continuity and change in African population mobility, while I. F. Masser, now a consultant planner, looks from another angle at changing patterns of African employment in Southern Rhodesia. Settlement is the subject of Dr. G. Kay's study of the Ushi of Northern Rhodesia [as it was then], and F. Lees deals in detail with an example of Chinese settlement in Malaya over the past 130 years. Dr. Alice Dyson has made a brief summary of part of her lengthy doctoral thesis on land use in Trinidad.

Applied geography is represented by L. S. Bhat's essay on regional planning in India, and Prof. A. T. A. Learmonth's "Retrospect on a Project in Applied Geography in Mysore State" draws on his year of research there. It is left to the final essay by R. Lawton on "Liverpool and the Tropics" to bring Liverpool into the picture. He deals with the changing and expanding trade of the port from the early nineteenth century to the present day.

The volume is well produced; many of the essays are illustrated by clear, well-executed maps and diagrams. Diversity of interest should secure a place for this book in every serious library, even if its classification will stretch the ingenuity of librarians.

L. Dudley Stamp

MOUNTAIN PEOPLE

The Sherpas of Nepal

Buddhist Highlanders. By Prof. Christoph von Fürer-Haimendorf. Pp. xix+298+55 photographs and 2 maps. (London: John Murray, 1964.) 35*s*. net.

MANY anthropologists must have envied Prof. Haimendorf his chance. The Sherpa valleys of northern Nepal, closed to Europeans down the years, were opened to a few Western travellers and climbers from the start of the 1950's; the first reports of the Sherpas at home were of a friendly, welcoming, laughing people, with some special gift of cheerfulness—what better task than to put on record their exceptional way of life and to analyse its secret of success? By 1953 Prof. Haimendorf was in the field, and in just under ten years he spent a total of twenty-five months living and working with the Sherpas. Already a Himalayan anthropologist of international standing, he could use his rich chances to the full. He has already published shorter examinations of various problems, and now he gives a long and detailed account of the Sherpa way of life.

In the main it bears out the travellers' tales of spontaneous and rather simple gaiety, but some things indeed are new: there is, for example, far more division in society than had been recognized at first, with the semi-untouchable *khamendeu*, and with the original Sherpa families holding pride of place in the community over other waves of immigrants from Tibet. The structure of society is far more complex than the first impression of the Sherpas' open gregariousness had led one to expect, and yet it functions amicably. This may be traced to the ready acceptance of social obligations and responsibilities, largely on the basis of a rota, a system which is carefully and thoroughly described. There is an easy code of sexual morals. Then there is Buddhism, largely benign, which interests Prof. Haimendorf particularly, and on which he writes at length. His account of this is full and sympathetic: he is quite at home, for example, in dealing with such eastern specialities as re-incarnated lamas, offering us, if not outright belief, at least an apparent suspension of disbelief. Sherpa religion came from Tibet, and, as in pre-Communist Tibet, there are here many monks engaged in a wide variety of religious practices, but it would be wrong to see these as in any sense imposed on an indifferent laity who groan under the economic burden—Prof. Haimendorf shows that the great expansion in the Sherpas' religious foundations in fact came after the introduction of the potato had brought increased prosperity, and the practice of religion is the way in which the Sherpas choose to spend their surplus wealth. Yet, however cheerful the great religious festivals, however much at one are the monks and those who support them, it is hard for anyone who is not a Buddhist highlander to be really happy that so much energy and man-power,

good and learned man-power, should go to waste in the smoke of funeral rites.

It is so good that a scholar of Prof. Haimendorf's calibre could make this record of a traditional society before it evolves or disappears. For, as the Sherpas' isolation is being eroded, so their way of life must change, and even as one reads this book a host of unanswered questions spring to mind. Prof. Haimendorf refers to the trading rupture with Tibet. But what is the effect of the big expeditions, of the many visitors (of anthropologists, even) into the long-closed land? Moreover, what about the influx of refugees, the United Nations agricultural experts, the school at Khumjung? The Sherpas' society, so rare and valuable, must now adapt to a hurricane of change; and once one has known them and laughed with them and cared about them, one's main concern cannot be the past but the hazards lying ahead.

JENNIFER BOURDILLON

INORGANIC AND ANALYTICAL CHEMISTRY

Supplement to Mellor's Comprehensive Treatise on Inorganic and Theoretical Chemistry

Vol. 8, Supplement 1: Nitrogen (Part 1). Prepared under the direction of an Editorial Board. Pp. lxviii+619. (London: Longmans, Green and Co., Ltd., 1964.) 280*s*. net.

Boron Hydrides

By Prof. William N. Lipscomb. (The Physical Inorganic Chemistry Series.) Pp. ix+275. (New York and Amsterdam: W. A. Benjamin, Inc., 1963.) 15.40 dollars.

Boron-Nitrogen Chemistry

An International Symposium sponsored by U.S. Army Research Office—Durham at Duke University, Durham, N.C., April 23–25, 1963. (Advances in Chemistry Series, 42.) Pp. x+330. (Washington, D.C.: American Chemical Society, 1964.) 7.50 dollars.

Concise Inorganic Chemistry

By J. D. Lee. Pp. xii+248. (London, New York, Toronto and Princeton, N.J.: D. Van Nostrand Co., Ltd., 1964.) Paper-bound, 27*s*. 6*d*.; Clothbound, 50*s*.

Vapour Pressure of the Chemical Elements

By A. N. Nesmeyanov. Edited by Robert Gary. Pp. xiii+462. (Amsterdam, London, New York: Elsevier Publishing Co., 1963.) 105*s*.

Analytical Chemistry of Thorium

By D. I. Yabchikov and E. K. Gol'braikh. Translated by A. Aladjem. (Analytical Chemistry of Elements Series.) Pp. vi+250. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1963.) 80*s*.

Analytical Chemistry of Niobium and Tantalum

By Ross W. Moshier. (International Series of Monographs on Analytical Chemistry, Vol. 16.) Pp. v+278. (London and New York: Pergamon Press, 1964.) 90*s*.

Analytical Chemistry of Ruthenium

By T. D. Avtokratova. Translated by IPST Staff. (Analytical Chemistry of Elements Series.) Pp. 224. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1963.) 88*s*.

THE volume of Mellor follows the style of the supplements so far published. The collection of numerical data, often tabulated, is a most valuable feature. The table on p. 30, for example, gives recent values for the heat of dissociation of the nitrogen molecule varying from 115·3 to 272 kcal mole^{-1}. The theory is always concisely presented, as in the discussion of multiple bonded nitrogen. There is an excellent section on nitrides, occupying 90 pages. In this a reference to a paper giving details of the preparation of the important magnesium nitride has been overlooked. The section on ammonia is very complete and informative, although it does not seem to deal with deuterammonia. The account of the industrial synthesis of ammonia is very good; from a very large patent literature a critical and significant selection is presented. The oxidation of ammonia is dealt with only briefly; presumably this will appear in a later part concerning nitric acid. The section on active nitrogen does not include more recent work which has largely cleared up the nature of active nitrogen; the editors should have taken steps to have had the article brought up to date. The book is one which is indispensable in all chemical libraries.

The chemistry of boron is expanding at such a fast rate that summaries will be welcome. This applies particularly to the hydrides of boron. A book by one of the leading authorities must, therefore, raise hopes that chemists will now have before them a well-digested survey of the whole subject. The book by Lipscomb does not seem to me to meet this need in a wholly satisfactory way. The chemistry is dealt with only very briefly and the bulk of the text is concerned with structure, which, needless to say, is covered in great detail. The style, unfortunately, is not always clear and gives the impression of haste. The discussion of the three-centre bond is far from clear and specialized concepts such as equivalent orbitals are introduced without explanation. The book will appeal more to mathematical physicists than to chemists.

A section of boron chemistry of particular interest is concerned with compounds containing boron and nitrogen, and the book on this subject is very informative and interesting. It is true that it is largely concerned with the organic chemistry of boron, but this is so closely linked with the inorganic chemistry that it seems permissible to include it here. The text consists of a series of papers presented to a symposium, but the continuity is more evident than is common in books of this kind. Theory finds a place, but preparative chemistry and descriptions of reactions occupy a position of honour, and the volume as a whole is one which chemists with different interests should find attractive and valuable.

The concise survey of inorganic chemistry by Lee is a book which students at all stages should find useful and interesting. The author points out that a knowledge of valency theory is no substitute for a knowledge of chemical facts, and he attempts to combine these two aspects of the science; he hopes that his book is long enough to cover the essentials and short enough to be interesting. I think that he has been very successful in achieving what he set out to do, and also that there is a need for something of the sort to be done with organic chemistry, which is tending to become too stifling for students.

The book on the vapour pressure of the elements gives a good account of the methods of measurement and a critical discussion of the results. There is also a useful table of the physical properties of the elements. In modern technology a knowledge of the properties of metals at high temperatures is very important and a critical review of the vapour pressures is valuable. Recent recorded values of high-temperature melting and boiling points often differ by hundreds of degrees.

The three books on the analytical chemistry of thorium, niobium and tantalum, and ruthenium include more than the titles might suggest. They give, particularly that on ruthenium, valuable surveys of the general chemistry of the elements, and the physical properties. It is mentioned that the X-ray result that thorium has a face-centred cubic lattice has recently been corrected, that values for the melting point vary from 1,450° to 1,850° and for the boiling point from 3,000° to 5,200°. Niobium and tantalum are important elements, and a good survey of their analytical chemistry is welcome; it includes

X-ray and radiochemical methods. Ruthenium was discovered in Russia, and a book on it by a Russian author continues the tradition. The original is one of a series intended to comprise about fifty volumes and to be completed in about five years, issued by the Institute of Geochemistry and Analytical Chemistry of the U.S.S.R. Academy of Sciences. The translation leaves much to be desired; incorrect chemical names are used and sometimes impossible chemical reactions are given. Only an expert chemist could find a way through the mistakes. All three books have good bibliographies. J. R. Partington

SHOCK WAVES AND CHEMISTRY

Chemical Reactions in Shock Waves

By Edward F. Greene and J. Peter Toennies. Pp. xvi + 352. (London: Edward Arnold (Publishers), Ltd., 1964.) 65*s*. net.

In the past fifteen years, shock waves have become an important experimental tool for the physical chemist. In the shock tube, gas temperatures of thousands of degrees are attained within a few molecular collisions—instantaneously, in fact, compared with the rate of vibrational relaxation and chemical reaction. The gas is only heated for a millisecond, but the development of photoelectric and other optical devices with a rapid response makes it possible to measure both relaxation rates and equilibrium properties within this time.

The first two-thirds of this book is a revised version of a monograph first published in 1959 in *Fortschritte de Physikalischen Chemie*, which describes the hydrodynamic theory and experimental techniques used. It opens with a chapter comparing the shock tube to other methods, and listing its advantages and limitations. Among the latter might well have been included the difficulty in varying pressure and temperature independently over a wide range, and the complications that arise in making rate measurements in an adiabatic system. Exothermic reactions, in particular, are difficult because the flow is potentially unstable behind the front.

The next two chapters derive the conservation equations needed to calculate the density and temperature of the hot gas, and show how they can be solved for real gases. The complicated procedures involved in coupling these hydrodynamic equations to chemical equilibrium are carefully explained. After a brief account of shock-front structure, the analysis of experimental records of vibrational and chemical relaxation is given: it is a pity this section does not include a discussion of the effects of shock attenuation on rate measurements.

The chapter on the production of shock waves rightly concentrates on gas-driven shock tubes, and includes a useful account of deviations from one-dimensional flow due to boundary layer formation: these often limit the time of observation available. After this the methods, mainly optical, used to measure the velocity of the shock and the properties of the hot gas are described. The final chapter gives a detailed account of a few outstanding experiments chosen to illustrate the range of possible measurements.

The remaining third of the book is occupied by tables summarizing shock-tube work up to the middle of 1963. Each entry gives all the essential features of the investigation, object, method, results and comments. They are classified first by the type of investigation: equilibrium properties and equation of state of gases and condensed phases, spectra, transport properties, shock front structure, vibrational relaxation and reaction kinetics; and secondly by the substance investigated. The diversity of high-temperature topics investigated is matched by the variety of journals and reports in which the work appears. The authors are to be congratulated both on the completeness of these tables and on the skilful way the entries have been prepared and arranged.

The cover suggests that the book is intended for chemists and physicists who wish to apply shock waves to their own problems: they will find it a useful guide if they are not dissuaded from the technique by the complications that become evident in the early chapters. But the more specialized topics will be appreciated by those already working in this field, and both active and potential workers will find the tables of the greatest value. The volume is well produced, and the price is not unreasonable.

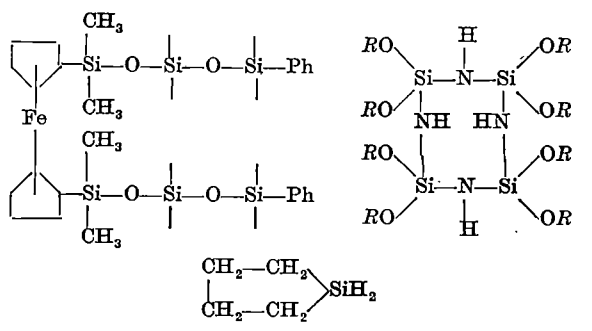
PREPARATION AND REACTIVITY OF ORGANOSILICON COMPOUNDS

Synthesis of Organosilicon Monomers

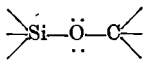


By A. D. Petrov, B. F. Mironov, V. A. Ponomarenko and E. A. Chernyshev. Authorized translation from the Russian by C. Nigel Turton and Tatiana I. Turton. Pp. 492. (New York: Consultants Bureau, 1964.) 22.50 dollars.

Chemists concerned with silicon polymers will be aware of the Russian publications on the relevant monomers. To have this essential information presented in English not only affords a means of checking items and impressions, but also greatly expedites the handing-on of knowledge to new postgraduates and to recruits into an industrial organization. It is a comfort to have this account of the experiences and views of the Russian chemists.

The use of the term 'monomers' is specific, and labels the compounds as precursors to polymers; but the chemistry described means much more than this, and fortunately the authors have assigned little space to polymerization. Rather may the book be considered to be a source of information for chemists, college or industrial alike, whose interests may not be in silicon polymers. Of more general significance are the reactive centres in the monomers, located by no means exclusively at the silicon atom. The influence of the silicon atom on the reactivity of atoms or groups, immediately or more remotely located, steric effects, and the transmission of electronic effects through the silicon atom, afford truly exciting properties for investigation. Therefore this ready access to vital information on the preparation of a series of organosilicon compounds having a stepwise range of reactivity is a windfall to many chemists who are not specifically committed to silicon polymers.

There are clear indications of the availability of the compounds, either by the usual laboratory facilities, or from commercial sources, and the three long tables dealing with unsaturated organosilicon compounds, aromatic organosilicon monomers, and physical properties of silicon hydrides, provide a list of the compounds prepared which can easily be scanned.



Details are given of the formation of the Si—C link by organometallic (for example, *R*Mg*X*), catalytic (Cu—Si 'direct' synthesis), and pyrolytic procedures. By subsequent processes, other atoms or groups are substituted for the reactive ones in the first stage product. Thus are constructed compounds with linkages depicted as follows:

Special features are, first, the silicohydrocarbons having alkenyl, $R_2Si(CH_2.CMe{=}CH_2)_2$, or alkynyl groups, and Si—H and Si—Si bonds; and secondly, the organosilicon hydrides, including compounds such as $RSiHCl_2$. In addition to the lithium aluminium hydride method, other procedures for forming the Si—H bond are described. Addition to a double bond is merely one example of the fascinating reactivity of the Si—H bond:

$$\rangle Si{-}H + CH_2{=}CHX \rightarrow \rangle SiCH_2CH_2X$$

The relative reactivity of the C—C and C—Si bonds has been much considered; but the variation of the relative reactivity of the Si—O and O—C bonds in:

and the basic function of oxygen in such compounds, according to the groups attached to Si and C, are matters in need of much further attention; p_π—d_π bonding to silicon from both the lone pairs on oxygen has been suggested as a probability in certain cases.

Points of comparison among the analogous compounds of Ge, Sn and Pb provide a fitting ending to *Synthesis of Organosilicon Monomers*, which deserves a place in every chemical laboratory whatever the bias.

ELECTRICAL CONDUCTIVITY OF GERMANIUM

Progress in Semiconductors
Vol. 8. Edited by Prof. Alan F. Gibson and Prof. R. E. Burgess. (A Heywood Book.) Pp. vi+244. (London: Temple Press Books Ltd., 1964.) 70*s*. net.

THE latest volume of *Progress in Semiconductors* departs from the usual practice in this series and contains only one article, a substantial contribution, by Dr. E. G. S. Paige, to the literature on germanium, devoted exclusively to electrical conductivity. The sheer bulk of the present data on the transport properties of semiconductors, and of germanium in particular, poses its own problems for the planner of review articles. In the present instance the editors have evidently considered that a closely related group of topics in a well-defined field could be treated advantageously, in a unified manner, by a single author. This inevitably involves a rather wasteful duplication of material—the present article overlaps several others which have appeared in earlier volumes. Moreover, in assessing the value of a work of text-book dimensions, the element of topicality plays little part in view of the lengthy period (two years in the present case) required for publication.

What Dr. Paige has provided is a workmanlike and authoritative monograph dealing in detail with the theory of electrical (bulk) conduction in germanium and its application to experimental results. The object has not been to shed new light on the foundations of the theory, or to examine controversial aspects, but rather to present a comprehensive account within a firmly established framework.

Of the five main sections the central, and longest, contains an analysis of experimental data on carrier mobilities, Hall effect and magneto-resistance effect, in terms of the relevant scattering mechanisms and the structure of the conduction and valence bands. High-frequency phenomena, including microwave cyclotron resonance, and impurity conduction are also dealt with, but in far less detail. The theoretical foundation is laid in the first two sections, which introduce the solutions of the Boltzmann equation, specific to the germanium band structure (and non-degenerate statistics), and the calculation of relaxation times from a detailed investigation of scattering mechanisms. The last two sections deal respectively with the effects of elastic deformations and 'hot electron' problems.

In a review article of this nature, where many results are quoted and few are derived, no concessions are made to the beginner—nor, indeed, would they be expected. This is essentially a work for specialists who already possess an adequate grasp of the subject. The book (for as such it must be regarded) suffers from one minor but irritating disadvantage: if it is opened at random, there is no clue, either from the page heading or from the labelling of the equations, which indicates the exact place. The list of contents at the beginning does not help since page numbers are not given. An adequate index is, however, provided. As a source of information on a field of much diversity and elaboration, this article should provide a useful work of reference for experimentalists and theoreticians who are directly concerned with the electrical properties of germanium.

VERTEBRATE ETHOLOGY

Social Behaviour and Organization among Vertebrates
Edited by William Etkin. Pp. xii+307. (Chicago and London: The University of Chicago Press, 1964.) 56*s*.

SOCIAL Behaviour and Organization among Vertebrates is a collective work developed as a result of the activities of the Textbook Committee of the Section of Animal Behaviour of the American Society of Zoologists. It aims at reviewing the activities of the past twenty-five years in the field of the social behaviour of animals as pursued not only by zoologists but also by experimental and clinical psychologists and other students of the behavioural sciences. Besides editing the work, William Etkin contributes four chapters which determine the scope and character of the book. The other five co-authors, Beach, Davis, Lehrman, Scott and Tinbergen, contribute a chapter each.

The book is wide-ranging and, for a co-operative work, well balanced. It gives a good general account, on the whole reasonably objective, of the contribution of modern ethology, and discusses such problems as the neuro-endocrine correlation in invertebrates, the physiological analysis of aggressive behaviour, the control of behaviour cycles in reproduction, and types of social organization in birds and mammals. The book extends far beyond the bounds hitherto considered respectable by the stimulus-response school of psychology so characteristic of North American thinking, and attempts, not always successfully, to get to grips with ethological principles, to interpret them and to relate them to sociological ideas and physiological facts. Topics as diverse as brain structure, "action-specific energy", drive, ritualization, imprinting, and innate releasive mechanisms are given special attention.

The significance of animal play is dealt with, and the widespread importance of the exploratory drive is understood. The views expressed as to the significance of the idea of instinct and the innate are somewhat muddled, and some of the very relevant contributions bearing on these problems, provided by European research workers (notably von Holst and Sokolov), are unaccountably omitted. Topics which seem to demand much more attention than they receive include homing and the orientation problem, and the development and spread of behavioural traditions in animals. A particularly excellent feature of the book is the abundance of clear and relevant illustrations coming from a wide variety of sources, some of them surprisingly and undeservedly unfamiliar. The work should be a valuable antidote for the students now being indoctrinated with the view that the whole of biology can really be summed up in the letters 'DNA'.
